

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

HORTENSIUS—KINGLAKE.

T H E
AMERICAN CYCLOPÆDIA:

A
Popular Dictionary
OF
GENERAL KNOWLEDGE.

EDITED BY
GEORGE RIPLEY AND CHARLES A. DANA.

VOLUME IX.
HORTENSIUS—KINGLAKE.

NEW YORK:
D. APPLETON AND COMPANY,
549 AND 551 BROADWAY.
LONDON: 16 LITTLE BRITAIN.
1874.

ENTERED, according to Act of Congress, in the year 1860, by D. APPLETON AND COMPANY, in the Clerk's Office of the District Court of the United States for the Southern District of New York.

ENTERED, according to Act of Congress, in the year 1874, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

Among the Contributors to the Ninth Volume of the Revised Edition are the following :

Prof. CLEVELAND ABBE, Washington, D. C.

HURRICANE.

WILLARD BARTLETT.

INDIA.
INDIAN ARCHIPELAGO.
KASHGAR.
KHOKAN.

Prof. C. W. BENNETT, D. D., Syracuse University.

HUNTINGDON, SELINA, Countess of.
JANES, EDMUND STONER.
KIDDER, DANIEL PARISH.

JULIUS BING.

ISMAIL PASHA, Khedive of Egypt,
KAULBACH, WILHELM VON,
and other articles in biography, geography, and history.

FRANCIS C. BOWMAN.

HUMMEL, JOHANN NEPOMUK.
JOSQUIN DES PRÉS.
KELLOGG, CLARA LOUISA.

T. S. BRADFORD, U. S. Coast Survey, Washington, D. C.

HYDROGRAPHY.

EDWARD L. BURLINGAME, Ph. D.

JOANNA I. and II., Queens of Naples,
JOHN, Archduke of Austria,
KENT, England,
and other articles in biography, geography, and history.

ROBERT CARTER.

THE
AMERICAN CYCLOPÆDIA.

HORTENSIVS

HORTENSIVS, Quintus, a Roman orator, born in 114 B. C., died in 50. At the age of 19 he made a speech in the forum, and gained the applause of the orators Crassus and Scævola. He joined the side of Sulla in the civil war, and afterward was a constant supporter of the aristocratic party. When Cicero first came to the forum Hortensius was called the *rex judiciorum*. Though professionally rivals, they seem to have lived on friendly terms; and in the beginning of the *De Claris Oratoribus*, Cicero pays an eloquent tribute to the memory of Hortensius. When obliged to leave the city on account of the impeachment of Clodius, however, Cicero was bitter against the supposed duplicity of Hortensius, and it was not till some time after his return that he was convinced of the injustice of his suspicion. In 81 Hortensius was made quæstor; in 75, ædile; in 72, prætor; and in 69, consul, with Q. Cecilius Metellus. The year before his consulship occurred the trial of Verres, in which the two rival orators were opposed. After his consulship, Hortensius took an active part against Pompey, opposing the Gabinian law, which gave Pompey the control of the Mediterranean sea, and the Manilian law, which transferred to his command the army against Mithridates. Cicero subsequently joined the same party, and we find them pleading often in common. They defended together C. Rabirius, L. Muræna, and P. Sulla. Ten years before his death Hortensius withdrew from public life. He had acquired great wealth, and owned villas at Tusculum, Bauli, and Laurentum.

HORTICULTURE, the most perfect method of tilling the earth so as to produce the best results, whether the products are objects of utility or of beauty. It is difficult to define the line between horticulture and improved agriculture upon the one side, and landscape architecture upon the other. Horticulture or gardening has been pursued from the earliest

HORTICULTURE

times of civilization or national refinement. Among the Romans, according to Pliny, small gardens filled with roses, violets, and other sweet-scented flowers were in repute; while many of the choicest plants and flowers which we now cherish were cultivated by the ancient Greeks. Horticultural art declined, however, with the fall of Rome, and not until long after did it revive under the monastic institutions. A part of the policy of Charlemagne was the establishment of gardens by royal edict, prescribing the very plants which were to be grown. In the 16th century several botanic gardens were founded by Alfonso d'Este, duke of Ferrara, and in consequence many other noblemen had fine gardens of their own. The Venetians and Paduans followed the example, and in 1555 a garden founded at Pisa by Cosmo de' Medici had become so rich in plants as to excite admiration. The garden at Montpellier in France, founded by Henry IV., contained before the end of the 16th century upward of 1,300 French, Alpine, and Pyrenean plants. At this time the garden at Breslau in Germany, to which the celebrated botanist Fuchs was attached, was in existence; and in 1577, at the suggestion of Bontius, was founded the garden at Leyden. In England, pleasure gardens with fountains and shady walks, with hedges and designs, were known from the time of the conquest, but it was not until the construction of conservatories for the preservation of tender plants that horticulture made much progress. According to Loudon, it was not till 1717 that such structures were furnished with glass roofs, and from this time a new era in gardening began. The education and training of young persons to the practice of gardening raised the occupation to an art, and has brought horticulture in European countries especially to a high rank.—We have considered horticulture as the acme of agriculture; and those familiar only with ordinary farm tillage

would be surprised to find how productive land can be made when husbanded by practical gardening. In the best market gardens the soil, by abundant manuring and working, is kept up to the highest attainable state of fertility, and is made to produce always two, and frequently three and four crops in a year. It often happens that a single acre near a large city yields the cultivator a greater profit than many entire farms bring to their owners. Within the last 30 or 40 years horticulture in the United States has rapidly advanced, and its progress has been largely due to the influence of the various horticultural societies, especially those of Pennsylvania and Massachusetts. In this country there are very few magnificent gardens; but in the diffusion of a knowledge of horticulture among the people at large there has been a steady advance, and a special literature pertaining to the science and practice of horticulture has sprung up. The large works of other countries upon the general subject are superior to any yet published here, but our works upon separate topics are more thorough and practical than those of any European country. Among the earlier horticultural works published in this country is "The American Gardener," by William Cobbett (New York, 1819). "The American Gardener's Calendar," by B. McMahon (Philadelphia, 1819), is one of the few works embracing every department of horticulture. In landscape gardening the leading authors are A. J. Downing, Copeland, Weidenmann, and Scott; in arboriculture, Warder, Hoopes, and Bryant; in flower gardening, including roses, Breck, Buist, Rand, Parkman, and Parsons. In floriculture under glass, "Practical Horticulture," by Peter Henderson (New York, 1868), is the only recent work. Among works on vegetable gardening, the most prominent are Burr's "Vegetables of America," White's "Gardening for the South," Quinn's "Money in the Garden," and Henderson's "Gardening for Profit." The leading agricultural journals have each a horticultural department with a competent editor, and there are now only three journals devoted solely to horticulture; these are: "The Horticulturist" (New York), established by A. J. Downing in 1846, and now (1874) edited by H. T. Williams; "The Gardener's Monthly" (Philadelphia, 1859), Thomas Meehan, editor; and "The California Horticulturist" (San Francisco, 1871), C. Stephens, editor.

HORTUS SICCUS. See HERBARIUM.

HORUS, a god of the Egyptians, son of Osiris and Isis. He represented the rising sun. He pierces with a spear the serpent Apophis or Apap, the vapors of dawn. He avenges his father Osiris, whom Set or Sutekh, also called Baal, kills, and whom the prayers of Isis resuscitate. The death of Osiris, the grief of Isis, and the final defeat of Set, the god of evil, are common themes in oriental mythologies, and recur in the stories of Cybele and Atys, and of Venus and Adonis. The youthful

Horus was held forth as a model for all princes, and as a type of royal virtues. He was often represented as a little child, sometimes in the lap of Isis, and always with a finger on his mouth, which is the common Egyptian sign indicative of extreme youth or infancy. The Greeks identified Horus with their god Harpocrates, whom they represented also with a finger on the lips; but mistaking the significance of the sign, they regarded it as a symbol of silence, secrecy, and mystery, and ascribed these attributes to the deity. He became accordingly a favorite subject for speculation with the later philosophers. His worship was also carried into Rome, where, probably on account of excesses committed in the mysterious rituals, it was for a while forbidden. The peach was considered the sacred fruit of the god. The Egyptians also believed that Horus held in conjunction with Anubis the balance in which the hearts of the dead are weighed before Osiris and the 42 assessors, and that he or Smon beheaded those found wanting on the *nemra* or infernal scaffold.

HORVÁTH, Mihály, a Hungarian historian, born at Szentes, Oct. 20, 1809. He was ordained as priest in 1830, and became in 1844 professor of the Hungarian language and literature in the Theresianum at Vienna. In 1848, during the Hungarian revolution, he was made bishop of Csanád, and *ex officio* a member of the upper house in the diet; and in 1849 he was minister of public worship and education. The Hungarian uprising having been overthrown, he took refuge first in France, and afterward in Belgium, Switzerland, and Italy, where for several years he prosecuted his studies in Hungarian history. In the mean while the Austrian government sentenced him to death in his absence. In 1866 he was permitted to return to his native country, and in 1869 he was unanimously elected member of the diet for Szegedin. His works on Hungarian history, in Hungarian, include "Hungarian History" (4 vols., Pépa, 1842-'6; abridged in 1 vol., Pesth, 1847; enlarged in 6 vols., 1859-'63; German translation, 2d ed., 1861); "Twenty-five Years of Hungarian History" (2 vols., Geneva, 1863; German translation, Leipsic, 1866); "History of the War of Independence in Hungary" (3 vols., Geneva, 1865); and "Reply to the Letters of Kossuth," a pamphlet setting forth the great importance for Hungary of the compromise with Austria in 1867. He has also published a collection of Hungarian historical documents in 4 vols.

HOSACK, David, an American physician, born in New York, Aug. 31, 1769, died Dec. 23, 1835. He studied in Columbia college from 1786 to 1788, thence went to Princeton college, where he graduated in 1789, and received his degree as doctor of medicine in Philadelphia in 1791. He subsequently continued his medical studies in London and Edinburgh; and on his return home in 1794 brought with him a cabinet of minerals obtained from Wer-

ner, and a collection of duplicate specimens of plants from the herbarium of Linnæus. This collection of dried plants gathered by Linnæus now constitutes a part of the museum of the lyceum of natural history of New York. In 1795 he was appointed professor of botany in Columbia college, and in 1797 of materia medica. In 1807 he became professor of materia medica and of midwifery in the newly created college of physicians and surgeons, and in 1811 of the theory and practice of physic and clinical medicine, to which were afterward added obstetrics and the diseases of women and children. He retained his post after the union of the two rival medical faculties of Columbia college and the college of physicians and surgeons in September, 1813. Resigning with the rest of the faculty in 1826, he aided in organizing the Rutgers medical school, which ceased in 1830. Dr. Hosack held several public medical offices, and was prominent in the promotion and management of municipal institutions. He founded in 1810, with Dr. Francis, the "American Medical and Philosophical Register," and was a fellow of the royal societies of London and Edinburgh. Among his works are: "A Biographical Memoir of Hugh Williamson, M. D., LL. D." (8vo, 1820); "Essays on Various Subjects of Medical Science" (3 vols., 1824-'30); "System of Practical Nosology" (1829); "Memoirs of De Witt Clinton" (4to, 1829); "Lectures on the Theory and Practice of Physic," edited by the Rev. H. W. Ducachet, M. D. (1838).

HOSANNA (Heb. *hoshv'ah na*, Save, we pray), in Jewish antiquity, a form of acclamation on joyous and triumphal occasions. At the feast of tabernacles it was customary to sing Ps. cxviii. 25, which contains the words *hoshv'ah na*, while the people carried green boughs of palm and myrtle and branches of willow. Hence the prayers were called hosanna, and the seventh day of the feast the great hosanna. The term was employed as a salutation to Christ on his public entry into Jerusalem.

HOSEA, the first of the minor prophets. He was the son of Beeri, commenced his prophecy about 785 B. C., and exercised his office at intervals for about 60 years. He was a resident of the kingdom of Israel, against which most of his prophecies are directed, rebuking and threatening the people for their sins, and exhorting them to repentance. His style is concise, sententious, and abrupt; and his prophecies are in one continued series, without any distinction as to the times when they were delivered or their subjects.

HOSMER, Harriet G., an American sculptor, born in Watertown, Mass., Oct. 9, 1830. She studied sculpture in the studio of Mr. Stevenson in Boston, also with her father, a physician, and in the medical college of St. Louis. In the summer of 1851 she commenced her first original work, a bust of Hesper. Late in 1852 she went to Rome, entered the studio of Gibson, and passed her first winter in modelling

from the antique. Her busts of Daphne and Medusa were her first attempts at original design in Rome, and were followed by a statue of Enone. For the public library of St. Louis she also executed her "Beatrice Cenci." In 1855 she modelled a statue of Puck, the popularity of which procured her orders for nearly 30 copies. In 1859 she finished a colossal statue of "Zenobia in Chains." This was followed by a statue of Thomas H. Benton in bronze for Lafayette park, St. Louis, and a "Sleeping Faun." She still resides in Rome (1874).

HOSPITAL (Lat. *hospitalia*, apartments for guests), an institution for the reception and relief of the sick, wounded, or infirm. The word has undergone great changes of signification. The earliest known hospital for the sick was founded in the latter part of the 4th century at Cæsarea; St. Chrysostom built one at his own expense in Constantinople; and Fabiola, the friend of St. Jerome, founded one at Rome. The Hôtel-Dieu in Paris, founded in the 7th century, has long been the largest and finest hospital in the world. It was rebuilt in the 12th century, and has been extended from time to time until now it covers five acres. The Hôtel-Dieu of Lyons, said to have been founded by Childebert in the 6th century, almost equals it. Rome had 24 hospitals in the 9th century; and in the 11th they began to be established for pilgrims in the Holy Land. Archbishop Lanfranc built a hospital at Canterbury in 1070. The oldest hospitals in London are St. Bartholomew's, which dates from 1546; Bethlehem, 1547; and St. Thomas's, 1553. In all civilized countries every considerable city now has one or more hospitals, sustained by charity, endowment, or government grants. Frequently they are connected with medical schools, for mutual advantage. Many have elaborate and costly buildings; but the latest theories are not in favor of permanent structures, which are believed to harbor the germs of disease. Military field hospitals, first known in the 6th century, have now, in connection with the ambulance system (see **AMBULANCE**), been made highly efficient. A yellow flag is the sign of a hospital.

HOSPITALLERS. See SAINT JOHN OF JERUSALEM, KNIGHTS OF.

HOTBED, in gardening, a bed of earth enclosed by a frame, which is covered by movable sashes, and heated from below by means of fermenting vegetable matter. In large establishments the hotbed is replaced by a glass structure heated by flues or by hot-water pipes. (See **GREENHOUSE**.) When vegetables are made to grow out of their proper season, they are said to be forced; large quantities of lettuce, radishes, &c., are forced for market in hotbeds during the winter months. The most general use of the hotbed is in starting such seeds as would germinate very slowly, if at all, in the open ground, and to forward plants for an early crop of those kinds that are later sown in the open air; by the use of the hotbed, plants six

weeks old, of cauliflower and cabbage for example, may be had for planting out at the time when the outside soil is dry and warm enough to allow of the sowing of seeds, thus enabling the gardener to produce a much earlier crop. The hotbed allows us to extend the season of many vegetables about two months; for instance, the season of tomatoes would be a very short one if we depended upon plants from seed sown in the open ground, but with the aid of the hotbed the plants may be so far forward as to be ready to flower at the time when it is safe to put them out. The usual heating material is horse dung; this is turned over a few times at intervals of a few days, and when in a state of active fermentation is laid up in a regularly formed bed 3 or 4 ft. thick, and a foot wider on each side than the frame of the hotbed; care is taken to have the manure evenly packed, and it is beaten with the fork to make it solid; the frame is then set upon the manure; fine, light, rich soil should be at hand, and when the thermometer shows that the heat of the bed (at first very violent) has receded to 90°, this is spread evenly over the manure to the depth of 6 or 8 in.; then the seeds may be sown. The use of one third or one half its bulk of forest leaves with the manure gives a more gentle and more lasting heat. The hotbed for a family garden is made in the manner described, and the frame, usually permanent, is large enough for two or three sashes. In market gardens the method is quite different. The regular hotbed sash is usually 6 x 3 ft.; the bars to hold the glass run longitudinally, there being no cross bars, but the glass is lapped at the edges about a quarter of an inch. The width of the bed is the length of the sash, and the length of the bed is determined by the number of sashes; an excavation is made 2½ ft. deep, and of the required size; this is boarded up with rough boards nailed to posts; the boarding extends above the surface of the ground 12 in. in front and 18 in. at the rear; cross pieces are nailed from front to rear, upon which the sash can slide. The manure is then placed in this pit and the soil put upon it as before described. Mats of straw or shutters of thin boards are provided to protect the bed in cold nights, and to afford shading when needed. The hotbed should be in a sheltered place well exposed to the sun; if need be, shelter from cold winds is afforded by making a fence, or setting up a wind-break of brush. As soon as the young plants are up they require the same care in weeding, thinning, watering, and loosening the soil, as those in the open ground; besides this, the sashes must be opened more or less, according to the weather, to prevent injury from too great heat, and when open must be closed should the outer temperature fall, to prevent damage from cold. Unless the beds are carefully attended to in both particulars, an hour of neglect may destroy the contents. Many plants require transplanting, when large enough, into other hotbeds before

they are finally set out. Before setting in the open ground the plants are hardened by gradually exposing them by the removal of the sashes whenever the night temperature will allow. The usual night temperature for a hotbed is 55° to 65°, and that in the day 70° to 80°. Where many varieties are to be sown in a bed, it is convenient, instead of sowing the seeds in the soil of the bed, to sow them in shallow wooden boxes 2½ or 3 in. deep. Besides seeds, roots of various kinds are forwarded in hotbeds; sweet potatoes are buried in the soil of the bed in order to get sets for planting; dahlia roots are started, and such slow-growing bulbs as tuberoses are best forwarded in this way before putting them out. A little bottom heat will often resuscitate a languishing plant or start a backward one into growth, and a hotbed is often useful as a place in which to plunge the pots of such plants. Where a very gentle and long continued heat is required, what is called a bark pit is used; in this spent tanner's bark, or waste tan, as it is called, takes the place of manure.

HOTHO, Heinrich Gustav, a German author, born in Berlin, May 22, 1802, died there, Dec. 25, 1873. He studied in Berlin, and was one of the most distinguished pupils of Hegel. In 1828 he became professor of history in the military school of Berlin, and in 1829 professor in the university; in 1830 assistant curator of the gallery of paintings, and in 1859 director of the collection of engravings in the royal museum. He published an edition of Hegel's *Vorlesungen über Aesthetik* (3 vols., Berlin, 1835-'8), and acquired celebrity as a historian and critic of Flemish and German art. His works include *Geschichte der deutschen und niederländischen Malerei* (2 vols., 1840-'43, left unfinished); *Die Malerschule Hubert's van Eyck*, &c. (2 vols., 1855-'9); and *Die Meisterwerke der Malerei vom Ende des 3. bis Anfang des 18. Jahrhunderts* (1865 et seq.).

HOT SPRINGS, a S. W. central county of Arkansas, intersected by Washita river; area in 1870, about 900 sq. m.; pop. 5,877, of whom 650 were colored. It has a hilly surface. The soil is very fertile in the river bottoms, and timber is abundant. It is traversed by the Cairo and Fulton railroad. The chief productions in 1870 were 5,796 bushels of wheat, 196,848 of Indian corn, 15,851 of sweet potatoes, and 843 bales of cotton. There were 964 horses, 3,896 cattle, 1,779 sheep, and 11,364 swine. The portion containing the hot springs whence its name is derived was set off to form Garland co. in 1873, reducing the area given above. Capital, Rockport.

HOT SPRINGS, a town and the capital of Garland co., Arkansas, about 45 m. W. S. W. of Little Rock, 6 m. N. of the Washita river, and 21 m. from Malvern on the Cairo and Fulton railroad; pop. in 1870, 1,276, of whom 296 were colored. It is built principally in the narrow valley of Hot Spring creek, running N. and S., and contains 8 or 10 hotels, 3

schools, 2 weekly newspapers, and 5 churches. In the vicinity is found valuable stone for hones and whetstones, of which considerable quantities are quarried. The springs (57 in number) issue from the W. slope of Hot Spring mountain, vary in temperature from 93° to 150°, and discharge into the creek about 500,000 gallons a day. They are much resorted to by invalids and tourists.—See "The Hot Springs as They Are," by Charles Cutter (Little Rock, 1874).

HOTTENTOTS, a people of South Africa, including the original inhabitants of the territory now occupied by Cape Colony. Van Kiebeek, the founder of this colony in 1652, states that they called themselves, according to the various dialects, Koi-koin, Tkuhgrub, Quenau, and Quaquas. It is supposed that the name of Hottentots was given them by the Dutch, probably in imitation of the clicking sounds in the language of the natives. The general characteristics of the Hottentots are a peculiarly livid and yellowish brown skin, crisp and tufted hair, a narrow forehead, projecting cheek bones, a pointed chin, a body of medium height and rather tough than strong, small hands and feet, and a flat and narrow skull. The Griquas are half-breeds descended from Hottentot mothers and Dutch fathers. The Hottentots are skilled in horsemanship, and are intelligent and courageous. They are of a mild disposition, but given to lying, stealing, drunkenness, and sensuality. They are ruled by chiefs who are controlled by councils. Their religious notions are centred in a supreme being, who is little else than a deified chieftain. They believe in a future life, and fear the return of spirits. They have various superstitions. They refuse to have their photographs taken lest it should deprive them of a portion of their life. They sometimes mutilate their hands as a protection against evil influences. As an example of their intellectual capacity may be mentioned the Hottentot Andreas Stoffles, who was master of several languages, and could make a good speech in English. The Damaras, a nomadic warrior tribe who came to South Africa from the central regions of that continent about the middle of the 18th century, are now almost extinct. Nearest related to the Hottentots are the Bushmen. See BUSHMEN, and ETHNOLOGY; also Fritsch, *Die Eingeborenen Südafrikas* (Breslau, 1872), and Perty, *Anthropologie* (2 vols., Leipsic, 1873-'4).—The Hottentot language has four dialects. The Nama dialect is spoken by the Namaquas (properly Nama-kha or Nama-na, *kha* and *na* being plural suffixes, the one of masculine, the other of common gender), N. W. of Cape Colony, and also by the Damaras, N. of them, but it does not seem to be their original tongue. It is the oldest and purest of the dialects, but, like the speech of all savages, it may be subdivided into several sub-dialects according to tribes and even families. The Khora dialect is spoken by the Koraquas (better Khora-kha or Kora-na),

N. of the upper Orange river, and is in age and purity greatly inferior to the Nama. The Cape dialect is the least cultivated of all, and no grammar of it has been published. The same is the case with the dialect of the eastern races. The Hottentot is, generally speaking, of a monosyllabic structure. It is rich in diphthongs and remarkably delicate in the use of inflectional final sounds, which contrast strangely with the constantly recurring initial clicking sounds. Flexional forms are produced by suffixes to the verbal root. Masculine, feminine, and common genders, and singular, dual, and plural numbers, are distinguished, and in case of pronouns not only in the third, but even in the first and second person. These distinctions, however, are not as clear as in other languages. The Bushman language also is considered a form of the Hottentot. Missionaries speak of it as hard and rough, and as represented by numerous dialects among the races of the desert and mountains of the interior.—See Tindall, "Grammar and Vocabulary of the Namaqua-Hottentot Language" (no date); Bleek, "Comparative Grammar of the South African Languages" (2 vols., Capetown and London, 1862-'9); and F. Müller, *Reise der Oesterreichischen Fregatte Novara: Linguistischer Theil* (Vienna, 1867).

HOTTENTOTS' BREAD. See TORTOISE PLANT.

HOTTINGER, Johann Heinrich, a Swiss philologist, born in Zürich, March 10, 1620, drowned June 5, 1667. He studied at Groningen, and afterward at Leyden. In 1642 he became professor of church history in Zürich, and in 1643 also of the Hebrew language; and in 1653 he was appointed to the chair of rhetoric, logic, and Scriptural theology. In 1655 he accepted the professorship of eastern languages and Biblical criticism at Heidelberg. On his return to Zürich in 1661 he was made rector of the university. His increasing reputation led to an invitation from the university of Leyden in 1667, which he was ready to accept, when, while crossing the river Limmath in the vicinity of Zürich, he was drowned by the upsetting of a boat, with several of his children. Among his works are *Thesaurus Philologicus, seu Clavis Scripturæ* (Zürich, 1649), and *Etymologicum Orientale, sive Lexicon Harmonicum Heptaglotton* (Frankfort, 1661).—His son, JOHANN JAKOB (1652-1735), wrote *Helvetische Kirchengeschichte* (Zürich, 1708-'29); and another JOHANN JAKOB, of the same family (1783-1859), wrote a *Geschichte der Schweizerischen Kirchentrennung* (Zürich, 1825-'7).

HOUDETOT, Elisabeth Françoise Sophie d', countess, a French lady celebrated by her association with Rousseau, born in Paris about 1730, died Jan. 22, 1813. She was a daughter of M. de la Live de Bellegarde, and married about 1748 the count d'Houdetot, to whom she bore a son in 1750. She left him toward 1753, and lived with the poet Saint-Lambert till his death in 1803. While residing at the château of Eau-Bonne near Andilly, and in the vicinity

of the Hermitage which her sister-in-law Mme. d'Épinay had fitted up for Rousseau, she renewed her acquaintance with the latter, whom she had previously met in her relative's house in Paris. He fell in love with her, and idealized her in his *Julie, ou la nouvelle Héloïse*, describing the vicissitudes of his passion and of his relation with her in his *Confessions*; but the countess protested against his exaggerations, and according to Rousseau's account as well as her own she remained faithful to her lover Saint-Lambert, although she felt much flattered by Rousseau's admiration. She had fine hair, but was far from handsome. When Saint-Lambert became idiotic in his old age she nursed him. Her husband, who died some 10 years before her lover, never lost his regard for her. Her son became a lieutenant general, and his three sons acquired eminence respectively in civil and military life and in literature.

HOUDIN, Robert, a French conjurer, born in Blois, Dec. 6, 1805, died there in June, 1871. His father, a watchmaker, gave him a good education at the college of Orleans, and at 18 years of age placed him in a lawyer's office; but having an extraordinary taste for mechanics, his father consented that he should learn watchmaking. While engaged in this occupation, the perusal of works on natural magic and a friendship formed with a travelling conjurer inspired him with an inclination for juggling. Having married, he went to Paris and engaged in his trade. He employed himself for a year in reconstructing a complicated machine, and so overstrained his mind as to lose all mental power for five years. After recovering he devoted himself for some time to making mechanical toys and automata, and at the Paris exhibition of 1844 obtained a medal for several curious figures of this kind. In 1845 he opened a series of exhibitions in juggling which became famous throughout Europe, and in 1848 he performed with great success in England. In 1855, at the great Paris exhibition, he gained the gold medal for his scientific application of electricity to clocks, and shortly after relinquished his exhibition to his brother-in-law Hamilton, retiring with a fortune to Blois. In 1856 the French government, finding that the Arabs in Algeria were frequently stirred up to rebellion by the pretended miracles of their marabouts or priests, invited Houdin to visit that colony, and if possible excel the magicians in their own tricks. He completely succeeded, passing through several very singular adventures while so doing. In 1857 he published *Robert Houdin, sa vie, ses œuvres, son théâtre*, and in 1859 his *Confidences*, which has been translated into English (Philadelphia, 1859). In 1861 he published *Les tricheries des Grecs dévoilées*, exposing the cheats of gamblers.

HOUDON, Jean Antoine, a French sculptor, born in Versailles, March 20, 1741, died in Paris, July 15, 1828. Having gained the first prize for sculpture in the royal academy at Pa-

ris, he passed ten years in Rome, and finished, among other works, the statue of St. Bruno in the church of Sta. Maria degli Angeli. Returning to Paris, he executed during the next 15 years admirable busts of Rousseau, Diderot, D'Alembert, Gluck, Turgot, Franklin, Mirabeau, and many other distinguished men; statues of Voltaire and Tourville; the "Diana" for the empress of Russia; the "Shivering Woman," and other works, which placed him in the first rank of French sculptors, and procured his admission to the academy. He made at this time the statue of a muscular skeleton of the human body, which he afterward reproduced in smaller size, and which has been often copied and used for the artistic study of anatomy. In 1785 he accompanied Franklin to the United States, to prepare the model for the statue of Washington ordered by the state of Virginia, and passed two weeks at Mount Vernon for that purpose. The statue, bearing the sculptor's legend, *Fait par Houdon, citoyen français*, 1788, in the hall of the capitol at Richmond, according to the testimony of Lafayette and other personal friends of Washington, is the best representation of him ever made. Among his later works were busts of Napoleon and Josephine and other celebrities of the first empire, and the statue of Cicero in the Luxembourg palace.

HOUGHTON, a N. W. county of the upper peninsula of Michigan, bounded N. W. by Lake Superior, indented on the N. E. by Keweenaw bay, and drained by Sturgeon river and other streams; area, about 2,000 sq. m.; pop. in 1870, 13,879. The surface is uneven and rocky, the N. W. portion consisting of the upper half of Keweenaw point, a peninsula lying between Lake Superior and Keweenaw bay, through which runs the Mineral range, and which contains Torch lake and Portage lake, discharging into the bay. Silver and iron ore are found, but the great wealth of the county is in its copper mines, which are situated in the Mineral range near Portage lake, the most productive being the Calumet and Hecla mine on the N. border. According to the census of 1870, there were 11 copper mines, employing 2,961 hands, and producing \$3,231,888 worth of ore. The product of 1872 was 12,602 tons (four fifths of the product of the Lake Superior region), of which the Calumet and Hecla mine yielded 9,800 tons. The ore is in a nearly pure state. The chief productions in 1870 were 8,595 bushels of oats, 22,040 of potatoes, and 703 tons of hay. There were 3 manufactories of clothing, 2 of iron castings, 1 of machinery, 1 of soap and candles, 12 of copper (milled and smelted), 4 of tin, copper, and sheet-iron ware, 4 breweries, 2 planing mills, and 5 saw mills. Capital, Houghton.

HOUGHTON, Richard Monekton Milnes, lord, an English author, born in Yorkshire, June 19, 1809. He graduated at Trinity college, Cambridge, in 1831, entered parliament as member for Pontefract in 1837, and represented that

constituency till Aug. 20, 1863, when he was raised to the peerage as Baron Houghton. He began his political life as a conservative, but soon allied himself with the liberals. In the house of commons he advocated popular education, religious equality, and measures for the reformation of criminals, and proved himself a warm friend of Italy in its struggles for unity and freedom. In early life he travelled much in southern Europe and in the East, and he has published several volumes of travels and a number of poems, some of the latter descriptive of oriental life and scenery. His works are: "Memorials of a Tour in Greece" (1833); "Memorials of a Residence on the Continent, and Historical Poems," and "Poetical Works" (1838); "Poetry for the People, and other Poems" (1840); "Memorials of Many Scenes: Poems" (1843); "Palm Leaves: Eastern Poems," "Poems Legendary and Historical," and "Poems of Many Years" (1844); "Good Night and Good Morning" (1859); "Monographs, Personal and Social" (1873); and "Poetical Works" (1874). He edited the letters and literary remains of John Keats, with a memoir (1848), has published many pamphlets and speeches on political topics, including "Thoughts on Party Politics," "Real Union of England and Ireland," and "Events of 1848, especially in their relation to Great Britain," and has contributed articles to the "Westminster Review" and other periodicals.

HOUGHTON, William, an English clergyman, born in Norwich in 1807. He graduated at Highbury college, London, in 1832, and in 1833 became minister of the Congregational church at Windsor. In 1844 he succeeded Dr. Robert Vaughan as minister of the Congregational society at Kensington, and in 1855 was elected chairman of the Congregational union of England and Wales, and delivered the "Congregational lecture," his subject being "The Ages of Christendom." Dr. Houghton has travelled extensively in the East, and has written many books, the most important of which is "The Ecclesiastical History of England" (4 vols., London, 1870). Among his other works is "Country Walks of a Naturalist with his Children" (1869). He represented the English Independents at the meeting of the evangelical alliance held in New York in 1873.

HOUND (*canis sagax*), the name of several varieties of large and powerful dogs hunting by scent, and trained to pursue the stag, the fox, the hare, and other animals, and even man. The progenitors of the hound races were probably, according to Hamilton Smith, the jungle koola (*lycaiscus tigris*, H. Smith) and the buansuah (*canis primævus*, Hodg.), both of the warmer parts of Asia. (See Dog.) These were domesticated after the more wolf-like varieties, and display in all the breeds a tendency to the three colors of white, black, and tan, characterizing them in their wild state. The cranium has a larger cerebral cavity than in less sagacious dogs, with a more convex fore-

head, wider space between the eyes for the organ of smell, and broader jaws; most varieties have also a wide nose, full and prominent eyes, large hanging ears, a raised and truncated tail, and often a spurious toe on the hind feet. There are two races, the one with short hair, the hounds proper, and the other with long hair, like the setter and spaniel, and used as gun and water dogs; the pointer seems to occupy an intermediate place between them. The faculties which make the hounds so useful in hunting must have existed in the original species, and have been cultivated in regard to special game according to the fancy of man; the blood, stag, and fox hounds have no intuitive tendency to pursue respectively man, the deer, and the fox, and these only, but have been trained with great care to hunt a single game. The most ancient form of hound figured upon the Egyptian monuments resembles much the bloodhound, which was formerly so much esteemed for its sagacity, strength, and olfactory acuteness. The bloodhound, once employed to trace felons, enemies, and fugitives, or to bring the huntsman to the retreat of a wounded animal, has been fully described under that title; it is now kept in civilized countries rather for show than use. The stag hound is but little smaller than the bloodhound, and like it is slow, sure, and steady; in fact it is a mongrel bloodhound, the cross being either some greyhound or swift fox hound; it has a large, rather short and sharp head, long hanging ears, muscular limbs, small feet, and tail carried high; the color is always more or less white with fulvous markings. Stag hunting, as performed in the fatiguing and cruel manner of the 17th and 18th centuries, is now rare, and this form of hound has become nearly if not entirely extinct. The fox hound of the present day is a perfect model of

English Fox Hound.

a hunting dog, and is a carefully bred cross between the bloodhound and the greyhound, probably with the intermixture of the southern English and perhaps other hounds; exactly how it has attained its present character it is impossible to determine. It is lower at the shoulders

and more slenderly built than the stag hound, with shorter hair, and the color is white, with larger clouds of black and tan, one on each side of the head, covering the ears, another on each flank, and a third at the root of the tail. Its speed is such that none but a thoroughbred hunter can keep up with it, and its endurance so great that a pack has been known to run for ten hours, tiring out three changes of horses, and severely testing the strength of the sportsmen. Breeders differ as to the best size for fox hounds, but from 22 to 24 in. high at the shoulder is generally considered the most advantageous. The best food is thought to be oatmeal and well boiled horse flesh, attention being paid to their constitution, the season of the year, and amount of work to be done. The cry of a pack of hounds, once so cheering and melodious, has lost much of its romantic interest from the change man has effected in the character of these animals; the other good points of a hound, such as pureness of stock, beauty of form, speed, endurance, and acuteness of smell, are more highly prized in a pack than harmonious voices. The average value of an established pack of fox hounds may be set down at about £1,000, though some have been sold for more than twice that sum; single hounds are often sold as high as 100 guineas. (See BEAGLE, BLOOD-HOUND, DOG, GREYHOUND, and HARRIER.)

HOUNSLOW, a town of Middlesex, England, 10 m. W. S. W. of London; pop. in 1871, 9,294. It consists of a single street, which stretches along the Great Western road from London. On Hounslow heath, which previous to the present century was frequently the scene of highway robberies, now stand gunpowder mills.

HOUB (Gr. *ῥα*; Lat. *hora*), a measure of time equal to $\frac{1}{24}$ of a mean solar day, or this proportion of the period between sunrise and sunrise at the time of the equinoxes. Thus applied, it becomes a definite measure; but as employed by the ancients to designate $\frac{1}{24}$ of the natural day, it was an indefinite period, varying with the times of rising and setting of the sun, times which continually changed with the season, and between increasing extremes as the observations were made in higher and higher latitudes. Even in the latitude of Rome, the length of the hour on June 25 was about $\frac{1}{24}$ part of 15 hours 6 minutes, as now reckoned, and on December 23 it was only $\frac{1}{24}$ part of 8 hours 54 minutes. At the two equinoxes only would the hour agree with its present measure. Hours thus divided were known as "temporary hours," in reference to their constant change of length. When the day was thus first divided is unknown. Herodotus states that the Greeks obtained the practice from the Babylonians. Wilkinson, however, says that "there is reason to believe that the day and night were divided, each into 12 hours, by the Egyptians, some centuries before that idea could have been imparted to the Greeks from Babylon." The division of the night as well as the day into 12 equal parts was

not practised by the Romans until the time of the Punic wars, and the use of equinoctial hours was not adopted till toward the end of the 4th century of our era; the first calendar known to have been made after this system is the *Calendarium Rusticum Farnesianum*. Hours are now reckoned in common practice in two series of 12 each, from midnight to midday, and from this to midnight, which corresponds to the supposed divisions of the ancient Egyptians. Astronomers count 24 hours from one midday to the next; and the Italians 24 hours from one sunset to the next, changing the commencement of the day with the season. The Chinese divide the day into 12 hours, one of their hours being equal to two of ours. They reckon from an hour (of our time) before midnight. In the use of clocks in the 11th century it was the duty of the sacristans of the churches to regulate the *horologia* each morning.

HOUB CIRCLES, or **Horary Circles**, great circles of the sphere, passing through the poles, and consequently perpendicular to the equator. They are meridians at every $\frac{1}{24}$ part of the circumference, their planes thus making angles of 15° with each other.

HOUBIS, the black-eyed damsels of the Mohammedan paradise, formed of pure musk, and made by a peculiar creation perpetual virgins. They dwell in green gardens and pearl pavilions, among lotus and acacia trees, with fruits in abundance, near flowing streams, reposing on lofty couches adorned with gold and precious stones. Some of the pavilions which they occupy are 60 miles square. The very meanest of the faithful will have 72 houris, besides the wives which he married when living. They join in concert with the angel Israfil, the most melodious of God's creatures, and the branches of the trees give an Æolian accompaniment. They may, if they desire, have children, which within an hour shall be conceived, born, and grow to maturity. Algazali regards the descriptions of the houris in the Koran as allegorical, and designed to convey an impression of the spiritual beatitude of the saints; and the orientalist Hyde affirms that an enlightened belief prevails among the wiser Mohammedans.

HOUBS, in mythology. See HORÆ.

HOUSATONIC, a river of New England, which rises in Berkshire co., Mass., flows into Connecticut, winds through Litchfield co., forms a part of the boundary between New Haven co. and Fairfield co., and falls into Long Island sound below Milford. Its entire length is about 150 m. Its scenery in general is very picturesque, and on its banks are numerous large mills. The Housatonic railroad follows its course for about 75 m.

HOUSELEEK (*sempervivum*, Linn.), a genus of plants of the natural order *crassulaceæ*, having thick succulent stems and leaves, the former frequently short, with the leaves so closely crowded upon them as to form a dense rosette,

and ornamental flowers, either yellow or red. The houseleeks are found in the mountains of southern and central Europe, the Canaries, and various parts of Asia and Africa. The common houseleek (*S. tectorum*, Linn.) has very thick, succulent leaves, disposed about a

Common Houseleek (*Sempervivum tectorum*).

short stem in a circular manner. It will grow in the most scanty soils and where it is exposed to drought, patches of it several feet in circumference thriving for years upon the exposed surfaces of rocks that are partially shaded. In Europe it is very common upon the thatched roofs of houses; it was formerly supposed to serve as a protection from lightning, and in early times every house was required, to have it; the custom still prevails, and it is said that the plant tends to preserve the thatch. Within a few years the taste in gardening has led to the use of sempervi-

Cobweb Houseleek (*Sempervivum arachnoideum*).

vums and other succulents for forming beds of a mosaic of living plants. The neat compact habit of the houseleeks and the related cotyledons, echeverias, &c., as well as the variety in color presented by the leaves, espe-

cially adapt them to this purpose; and these plants, which were formerly kept as single specimens by the curious, are now raised by the florists in large quantities for ornamental planting. One of the most valued for this purpose is *S. calcareum* from the Alps (incorrectly *S. Californicum* of florists), and several others are employed. A very striking and interesting little species is the cobweb houseleek (*S. arachnoideum*), also an alpine species; its rosettes, about an inch across, grow close together in large clumps; the tiny leaves are connected by a fine down which passes from tip to tip, making the plant look as if an industrious spider had spun its web over it. Where sparrows abound the plant cannot be grown in perfection, as these birds rob it of the web to use in their nests. The tree houseleek (*S. arboreum*), from the Canaries, has a branching stem 3 ft. or more high, each branch terminated by a handsome rosette

Tree Houseleek (*Sempervivum arboreum*).

of green leaves, or in the varieties yellow margined or purple. It is a greenhouse plant, and was formerly common as a window plant. —The houseleeks are not remarkable for useful qualities. The fresh leaves of the *ensão* of Madeira (*S. glutinosum*, Aiton) are used by the fishermen to rub upon their nets, to preserve them. Malic acid combined with lime exists in *S. tectorum*. Its juices are considered cooling, and its bruised leaves are used in domestic practice as applications to burns, ulcers, and inflammation, and from them also a simple and cooling salve is prepared.

HOUSSA, or **Hausa**, a country of central Africa, bounded N. by the Sahara, E. by Bornoo, S. by Nufi, and W. by the Quorra. The people are negroes, and the Foolahs or Fellatahs are the ruling race. Barth found the country divided into 10 provinces. Kano, in the province of the same name, is the principal city in point of commerce, and has about 30,000 inhabitants; it is in lat. 12° 0' 19" N. and

lon. 8° 40' E. Katagum, E. by N. of Kano, has from 7,000 to 8,000 inhabitants. Sackatoo, in the N. W. part of the country, has upward of 20,000 inhabitants, and has one of the best supplied markets in central Africa. Wurmo, 15 m. N. E. of Sackatoo, on the river Rima, is a new town founded in 1831; its population is about 12,000. Zaria, the capital of the province of Zegzeg, is in lat. 10° 59' N. and lon. 8° E.; it is surrounded by a beautiful and highly cultivated country, and its population is estimated at 50,000. Houssa is well watered, being traversed by the rivers Sackatoo, Mariadi, Zirmie, Bugga, Zoma, and other tributaries of the Niger. It is considerably elevated above the sea, and its climate is consequently cooler and more healthy than that of the other countries of central Africa. The land is well cultivated, the principal crop being Indian corn, of which two harvests are annually produced. Cotton is largely raised, and Kano is famous throughout central Africa for its dyed cloths. Tobacco, indigo, rice, and various kinds of grain and fruits, are diligently cultivated. At Sackatoo there are extensive manufactures of leather, iron, and cotton cloths; and an active commerce is carried on in all the cities by means of open markets, which are frequented by traders from the neighboring countries and from remote parts of the continent. The people of Houssa are mostly Mohammedans. They have attained to some degree of civilization, have a written language, and have historical records reaching back to the 13th century of our era. They were converted to Mohammedanism in the 16th century, and were conquered by the Foolaahs in 1807, when Katsena, then their principal city, surrendered after a desperate defence of seven years.

HOUSSAYE. I. **Arsène**, a French author, born at Bruyères, near Laon, March 28, 1815. While young he went to Paris, where his two novels, *La couronne de bluets* and *La pécheresse*, appeared in 1836. The friendship of Jules Janin and Théophile Gautier, and his association in work with Jules Sandeau, aided to establish him in the literary world. From 1844 to 1849 he was editor of *L'Artiste*, and his *Histoire de la peinture flamande et hollandaise* (fol., 1846) was aided by a subscription of 50,000 francs from the government. This work was received with popular favor, although charged with plagiarism. At the revolution of 1848 he was thrown into political prominence, and was an unsuccessful candidate for the assembly. He was manager of the Théâtre Français from 1840 to 1856, and he became one of the most notorious courtiers of the second empire. In 1861 he became one of the proprietors and the managing editor of *La Presse*. His numerous writings include poetry, plays, essays, and popular sketches of celebrated and fashionable women. Among them are *Nos grandes dames* (4 vols., 1868), *Les Parisiennes* (4 vols., 1869-70), and *Mademoiselle Cléopâtre* (new ed., 1874). II. **Henry**, a French author, son of the preced-

ding, born in Paris, Feb. 24, 1848. He became known in 1867 by his *Histoire d'Apelles*, and his subsequent works include *Histoire d'Alcibiade et de la république athénienne depuis la mort de Périclès jusqu'à l'avènement des trente tyrans* (2 vols., Paris, 1874).

HOUSTON. I. A central county of Georgia, bounded E. by the Ocmulgee river, which is navigable by steamboats, and drained by several of its affluents; area, 875 sq. m.; pop. in 1870, 20,406, of whom 15,332 were colored. The surface is undulating, and the soil, of limestone formation, is very fertile. The Southwestern railroad passes through the county. The chief productions in 1870 were 3,536 bushels of wheat, 363,895 of Indian corn, 40,107 of sweet potatoes, and 3,819 bales of cotton. There were 834 horses, 2,730 mules and asses, 1,502 milch cows, 3,890 other cattle, and 10,963 swine; 1 manufactory of agricultural implements, 3 of carriages, 1 of cotton goods, 1 flour mill, and 7 saw mills. Capital, Perry. II. A S. E. county of Texas, bounded E. by Neches river, and W. by Trinity river, both navigable; area, 1,090 sq. m.; pop. in 1870, 8,147, of whom 3,542 were colored. It has a highly fertile soil, and a rolling surface diversified in some places with hills, and well timbered with oak, pine, ash, hickory, black walnut, &c. The Houston and Great Northern railroad traverses it. The chief productions in 1870 were 33,163 bushels of Indian corn, 5,779 of sweet potatoes, and 920 bales of cotton. There were 297 horses, 2,684 cattle, and 3,171 swine. Capital, Crockett. III. A N. W. county of Tennessee, formed since the census of 1870, bounded W. by the Tennessee and N. E. by Cumberland river; area, about 350 sq. m. The surface is undulating and the soil fertile. The Louisville and Nashville and Great Southern railroad passes through the N. part. The assessed value of property in 1871 was \$344,775. Capital, Erin. IV. A S. E. county of Minnesota, separated on the E. from Wisconsin by the Mississippi, bordering on Iowa on the S., and intersected by Root river; area, about 575 sq. m.; pop. in 1870, 14,936. The surface is undulating and mostly wooded, only about a fifth being occupied by prairies. The soil, resting on magnesian limestone, is very fertile. The Southern Minnesota and the Chicago, Dubuque, and Minnesota railroads intersect it. The chief productions in 1870 were 623,557 bushels of wheat, 249,761 of Indian corn, 227,688 of oats, 31,182 of barley, 32,065 of potatoes, 27,560 lbs. of hops, 14,286 of wool, 229,183 of butter, and 14,776 tons of hay. There were 2,917 horses, 3,614 milch cows, 4,536 other cattle, 4,697 sheep, and 6,305 swine; 1 car factory, 6 flour mills, and 2 saw mills. Capital, Caledonia.

HOUSTON, a city and the capital of Harris co., Texas, the second city in the state in population and importance, situated at the head of tide water on Buffalo bayou, 45 m. above its mouth in Galveston bay, 46 N. W. of Galves-

ton, and 150 m. E. S. E. of Austin; pop. in 1860, 4,845; in 1870, 9,382, of whom 3,691 were colored; in 1874, estimated by the local authorities at 20,000. It is built on the left bank of the bayou, which is spanned by several bridges, the principal ones being of iron, and embraces an area of 9 sq. m. The city hall and market house of brick, just finished at a cost of \$400,000, is 272 ft. long by 146 ft. wide, and has two towers, 14 by 21 ft. and 114 ft. high. It contains a hall, 70 by 110 ft., fitted up for public entertainments and capable of seating 1,300 persons. The masonic temple is a handsome structure costing \$200,000. The principal hotel, the largest in the state, has accommodations for 500 guests. The city is lighted with gas, and is easily drained. The construction of street railroads and grading of streets are in progress. Houston is the centre

of the railroad system of the state, and attracts the trade of the surrounding country, which is rich in grazing and agricultural products. There are six diverging lines: the Houston and Texas Central; the Houston and Great Northern and International; Houston Tap and Brazoria; Galveston, Houston, and Henderson; New Orleans and Texas; and Buffalo Bayou, Brazos, and Colorado. The bayou opposite the city has a depth of 5 ft., but owing to bars in Galveston bay vessels drawing more than 4 ft. cannot reach this point. Improvements are in progress by the United States government and an incorporated company, which will render Houston accessible by vessels drawing 9 ft. The navigation of the bayou is mainly controlled by the Houston direct navigation company, which has a capital of \$300,000, and owns 6 steamers, 4 tugs, and 24 barges. The

Market and Opera House, Houston.

whole number of vessels regularly engaged in the trade of the bayou in 1872 was 71, viz.: steamers, 10; tugs, 6; barges, 30; schooners, mostly employed in the lumber trade with the Sabine, Louisiana, and Florida coasts, 25. An extensive lumber trade is also carried on by flatboats with the bayous emptying into Buffalo bayou and San Jacinto river. The principal business, however, is manufacturing, in which Houston surpasses all other places in the state. The chief establishments, besides the extensive machine shops of the railroads, are 2 cotton factories, 4 iron and brass foundries, 3 car factories, 4 planing mills and wood works, 5 manufacturing of furniture, 2 of soap, 1 of cement pipe, 1 of bone dust, 5 sheet-iron and tin works, 5 carriage and wagon works, 1 beef-packing and ice-manufacturing establishment, and 7 brick yards. There are three nurseries, two

fire and marine insurance companies, a cotton press company, two national banks with a capital of \$200,000, and a state bank with \$500,000 capital. The valuation of property in 1873 was \$7,669,625. The state fair is held here annually. The city contains 14 public schools, which in 1872 had 26 teachers and 1,228 pupils, two public libraries with about 3,000 volumes, three daily and six weekly newspapers, two monthly periodicals, and 12 churches.—Houston was settled in 1836, and in 1837 was temporarily the seat of government.

HOUSTON, Sam, an American soldier, born near Lexington, Va., March 2, 1793, died at Huntersville, Texas, July 25, 1863. His father served in the revolutionary war, and held the post of inspector of brigade till his death in 1807. His mother, after her husband's death, emigrated with her six sons and three daugh-

ters to East Tennessee, within 8 m. of the Cherokee country. Sam had read a few books, among them Pope's translation of the Iliad, of which he could repeat nearly the whole from memory. He desired to learn Greek and Latin, but was refused by his schoolmaster, upon which he left the school, and entered a store as clerk. This occupation he had no relish for, and absconding, he crossed the Tennessee river, and lived with the Indians about three years. Though under 18 years of age, he was six feet high and an active hunter, and stood high in the esteem of his savage associates. Oolooteka, one of their chiefs, adopted him as his son. In 1811 he returned to his family, and opened a school. In 1813, during the war with Great Britain, he enlisted as a common soldier, was promoted to be an ensign, and fought under Jackson against the Indians at the battle of the great bend of the Tallapoosa, March 24, 1814, where he was severely wounded. After the ratification of peace in 1815 he was promoted to be a lieutenant, and was stationed near Knoxville, Tenn., and afterward at New Orleans. In November, 1817, he was appointed a subordinate Indian agent to carry out the treaty with the Cherokees which had just been ratified. In the following winter he conducted a delegation of Indians to Washington. Complaints were made against him to the government on account of his exertions to prevent the unlawful importation of African negroes through Florida, then a Spanish province. He was acquitted of all blame by the government; but conceiving himself to be ill treated, he resigned his commission in the army, March 1, 1818, settled in Nashville, and began to study law. In six months he was admitted to the bar, and began practice in Lebanon, 30 m. E. of Nashville. He was soon appointed adjutant general of the state, with the rank of colonel; and in 1819 he was elected district attorney of the Davidson district, and took up his residence in Nashville. In 1821 he was elected major general of militia, and in 1823 a representative in congress. He was re-elected in 1825 by an almost unanimous vote, and in August, 1827, was chosen governor of Tennessee. In January, 1829, he was married, and in April, for reasons unknown to the public, separated from his wife, resigned his office, went to the west of Arkansas, to which his former friends the Cherokees had removed, and presented himself before Oolooteka, who had now become the principal chief of the tribe. He was kindly received, and by an official act of the ruling chiefs, Oct. 21, 1829, was formally admitted to all the rights and privileges of the Cherokee nation. In 1832 he went to Washington to remonstrate against the frauds and outrages practised upon the Indians. This resulted in the removal of five government agents from office, and he became involved in a series of personal and legal contests with the removed agents and their friends. He was accused in the house of rep-

resentatives by W. R. Stansbury of Ohio having attempted to obtain from government a fraudulent contract for Indian rations. This led to a personal rencontre between Houston and Stansbury, who was severely beaten. For this Houston was arrested, and publicly censured by the speaker of the house. He was also tried for assault, and fined \$500; but the sentence of the court was not enforced, and the fine was afterward remitted by President Jackson. A committee of which Mr. Stansbury was chairman was appointed to investigate the charge of fraud, but reported that it was not sustained. Houston returned to his wigwam, and in December, 1832, went to Texas, where a revolutionary movement was organizing against the Mexican government. In the constitutional convention, which met April 1, 1833, Houston exercised a controlling influence. When the war with Mexico began he was chosen general of the military district east of the Trinity, and in October, 1835, mustered his forces and led them to the camp of Gen. Austin, who was besieging Bexar. He was soon elected commander-in-chief of the Texan army. After the declaration of Texan independence, he resigned his command, and was immediately reelected commander-in-chief of the army of the new republic. On March 10, 1836, he went to the camp of Gonzalez and took command of the army of 374 men, ill organized, poorly armed, and without supplies. The fort of the Alamo had just been taken by the Mexicans, and its garrison of about 170 put to death. On March 12 information reached the camp of this massacre, accompanied by the statement that the president of Mexico, Santa Anna, was close at hand with an army of 5,000 men. The wildest panic seized the Texan camp. Houston promptly restored order, and fell back to the Colorado, receiving from time to time small reinforcements, till at length the entire number of his force was 650 men. He had no artillery, and Col. Fannin, who was stationed at Goliad with 500 men well armed and supplied with artillery, was ordered to join him; but he was intercepted by a vastly superior force, and after a desperate defence capitulated, March 20, and with his command of 357 was massacred in cold blood, March 27. Santa Anna advanced to Harrisburg, the capital, which he laid in ashes, and marched upon the town called New Washington. Here upon the San Jacinto he was encountered by Houston, who had at length received two six-pounders from Cincinnati. His force had been increased till it numbered 783 men, all volunteers, most of whom had never seen a battle; but, led in a general charge by Houston, with shouts of "Remember the Alamo!" "Remember Goliad!" they utterly routed (April 21) the Mexican force of 1,600 regulars, of whom 630 were killed and nearly all the remainder captured. The Texans had only 8 killed and 25 wounded. The next day Santa Anna, disguised as a common soldier, was captured and brought

before Houston, who rebuked him for the cruel and perfidious massacres of Goliad and the Alamo, but protected him from the wrath of the Texans. A treaty made with the captive president secured the independence of Texas. Houston, who had been severely wounded in the ankle, was relieved from the command of the army, and sailed for New Orleans, where he arrived almost in a dying condition. In July, however, he returned to his home in Nacogdoches. In the following September he was elected president of Texas, and was inaugurated Oct. 22, 1836. He appointed his political rivals to important offices, liberated Santa Anna, and opened negotiations with the United States government for the annexation of Texas to the Union. His presidential term expired Dec. 12, 1838; and as the constitution made him ineligible for the next term, he was succeeded by Mirabeau B. Lamar. During the three years of the next presidential term Texas became involved in wars with the Indian tribes on her borders, in disastrous expeditions against the Mexican territories, and in debt to an enormous amount. The expenditures for the year 1841 amounted to \$1,176,288, and the receipts to only \$442,604. Houston, who had meantime been twice elected to congress, was reelected president in September, 1841, by more than three quarters of the votes. After a stormy administration, beset at the outset with difficulties of the gravest character, which were met with firmness and overcome with great judgment and ability, he retired from his second presidential term in December, 1844. He had paid off a large amount of the national debt, had kept the expenditures far within the revenues, restored peace and trade with Mexico, made treaties with all the hostile Indian tribes, and lastly had negotiated successfully the great measure of annexation to the United States, though its final consummation did not take place till after the expiration of his constitutional term of office, when he was once more ineligible. Texas became one of the United States in 1845, and Sam Houston and Thomas J. Rusk were the first senators she sent to Washington. Houston was reelected at the end of his term in 1853, and remained in the senate till March 4, 1859. As a senator, he was the zealous advocate of justice and humanity to the Indians. He opposed the Kansas and Nebraska bill, in a speech March 3, 1854, and gave in his adhesion to the "Know-Nothing" or American party. In 1858 he voted against the Lecompton constitution of Kansas. On Aug. 1, 1859, he was elected governor of Texas. He opposed secession in 1861, and long resisted the clamor for an extra session of the Texas legislature; and he finally resigned his office in preference to taking the oath required by the convention.

HOVEDEN, Roger de, an English chronicler, born in Yorkshire about the middle of the 12th century. He was attached to the court of Henry II., and was employed in visiting mon-

asteries, and in watching over the revenues that accrued to the king on the death of the superiors. His history, *Annales Rerum Anglicarum*, is a continuation of the ecclesiastical history of Bede, beginning where he left off (731), and extending to 1202, the third year of the reign of King John. Its accuracy is attested by Sir Henry Savile, Selden, Leland, and Nicolson. It was published in Savile's *Scriptores post Bedam* (London, 1595), and translated by H. T. Riley for Bohn's "Antiquarian Library."

HOVEY, Alvah, an American clergyman, born in Thetford, Vt., March 5, 1820. He graduated at Dartmouth college in 1844. Having taught in the academy at New London one year, he studied theology at Newton, Mass., completing the course in 1848. He was pastor of the Baptist church at New Gloucester, Me., for one year, and in 1850 returned to Newton theological institution, and taught in the department of Biblical literature till 1853. He became professor of ecclesiastical history in 1853 and of theology and Christian ethics in 1855, which latter post he still retains (1874). He received the degree of D. D. from Brown university in 1856. He has published a translation of Perthes's "Life of Chrysostom," jointly with the Rev. D. B. Ford (Boston, 1854); "Life and Times of Backus" (1858); "The State of the Impenitent Dead" (1859); "The Miracles of Christ as Attested by the Evangelists" (1863); "The Scriptural Law of Divorce" (1866); and "Religion and the State" (1874).

HOWARD, the name of eight counties in the United States. **I.** A central county of Maryland, bounded N. E. by the Patapsco river, and S. W. by the Patuxent; area, 225 sq. m.; pop. in 1870, 14,150, of whom 3,474 were colored. It has an uneven surface, rising in some places into hills. The valleys are generally fertile. The Baltimore and Ohio railroad and the Washington branch pass through it. The chief productions in 1870 were 128,376 bushels of wheat, 415,719 of Indian corn, 204,877 of oats, 97,929 of potatoes, 182,980 lbs. of tobacco, 189,646 of butter, and 7,445 tons of hay. There were 2,958 horses, 3,100 milch cows, 3,056 other cattle, 2,516 sheep, and 8,441 swine; 3 cotton mills, 1 woollen mill, and 5 flour mills. Capital, Ellicott City. **II.** A S. W. county of Arkansas, formed in 1873 from portions of Hempstead, Pike, Polk, and Sevier cos. It is well watered by affluents of Little river and of the Little Missouri. The surface is irregular, consisting of hills, valleys, and river bottoms. The valleys and bottoms produce corn and cotton; the hills are better adapted to the smaller grains and fruit. Timber is abundant, and lead, silver, and marl are found. Capital, Centre Point. **III.** A central county of Indiana, traversed by Wildcat creek, an affluent of the Wabash; area, 279 sq. m.; pop. in 1870, 15,847. It has a level surface and an excellent soil. The Pittsburgh, Cincinnati, and St. Louis, and the Indianapolis, Peru, and Chicago railroads intersect at the

county seat. The chief productions in 1870 were 287,875 bushels of wheat, 356,401 of Indian corn, 34,031 of oats, 37,668 of potatoes, 46,429 lbs. of wool, 121,777 of butter, and 4,250 tons of hay. There were 3,803 horses, 2,687 milch cows, 4,424 other cattle, 14,393 sheep, and 14,656 swine; 5 flour mills, 3 planing mills, 36 saw mills, and 3 woollen factories. Capital, Kokomo. **IV.** A N. E. county of Iowa, bordering on Minnesota, and watered by the Wapsipinicon, Turkey, and Upper Iowa rivers; area, about 430 sq. m.; pop. in 1870, 6,282. It is well timbered, and has tracts of prairie. The Iowa and Minnesota division of the Milwaukee and St. Paul railroad crosses the N. E. corner. The chief productions in 1870 were 321,514 bushels of wheat, 120,234 of Indian corn, 263,258 of oats, 30,713 of potatoes, 408,351 lbs. of butter, and 14,880 tons of hay. There were 2,175 horses, 2,734 milch cows, 3,922 other cattle, 1,648 sheep, and 2,640 swine. Capital, New Oregon. **V.** A central county of Missouri, bounded S. and W. by the Missouri river, and drained by some of its small tributaries; area, 430 sq. m.; pop. in 1870, 17,233, of whom 5,193 were colored. It abounds in anthracite coal, and has quarries of limestone and sandstone. The surface is rolling, and the soil fertile. The chief productions in 1870 were 400,410 bushels of wheat, 917,335 of Indian corn, 152,490 of oats, 42,422 of potatoes, 788,132 lbs. of tobacco, 66,554 of wool, 126,216 of butter, and 3,856 tons of hay. There were 5,799 horses, 2,425 mules and asses, 4,103 milch cows, 7,326 other cattle, 19,156 sheep, and 35,094 swine; 2 manufactories of carriages, 4 of saddlery and harness, and 4 flour mills. Capital, Fayette. **VI.** A S. E. county of Kansas, bordering on the Indian territory, and drained by Suicide creek and other branches of the Arkansas, and by Fall river; area, 1,271 sq. m.; pop. in 1870, 2,794. The surface is undulating and the soil fertile. The chief productions in 1870 were 4,766 bushels of wheat, 26,795 of Indian corn, 2,710 of oats, 2,304 of potatoes, and 150 tons of hay. There were 243 horses, 502 milch cows, 1,348 other cattle, 592 sheep, and 435 swine. Capital, Elk Falls. **VII.** An E. central county of Nebraska, intersected by Loup fork of the Platte river and its branches; area, 576 sq. m.; not included in the census of 1870. **VIII.** A N. W. county of Dakota, bordering on Montana, recently formed and not included in the census of 1870; area, about 3,500 sq. m. It is bounded N. by the Missouri, intersected by the Little Missouri, and watered by other streams.

HOWARD, Charles, Lord Howard of Effingham, an English admiral, born in 1536, died Dec. 14, 1624. His father, William, son of Thomas, second duke of Norfolk, was lord high admiral of England and lord privy seal. The son was sent to France in 1559 to congratulate Francis II. on his accession to the throne, and served with credit on land and sea for many years. In 1585 he was appointed lord high ad-

miral, and in 1588 succeeded in averting from the English coasts the attack of the Spanish armada. In 1596 he participated with the earl of Essex in the capture of Cadiz and the destruction of the Spanish shipping there, for which service he was created earl of Nottingham. The appointment of Essex in the succeeding year to be hereditary earl marshal, with precedence over the lord high admiral, induced Lord Howard to resign the latter office; but he subsequently resumed it, and in 1599, during the alarm at the prospect of another Spanish invasion, and of an insurrection under Essex in Ireland, was appointed by the queen lieutenant general of England. He commanded the party which captured Essex in London, and retained his office under James I. until a few years before his death, when he resigned it in favor of Buckingham, receiving in compensation a pension of £1,000, and the acquittal of a debt of £1,800 due the crown.

HOWARD, Henry, earl of Surrey. See SURREY.

HOWARD, John, an English philanthropist, born in Enfield, Sept. 2, 1726, died in Kherson, Russia, Jan. 20, 1790. At 16 years of age he was apprenticed to a grocer in London; but upon the death of his father soon after, he purchased his indentures and travelled on the continent. Returning to England, he occupied himself with medical and scientific studies at Stoke Newington. About the age of 25 he experienced a severe attack of illness, and upon his recovery testified his gratitude to his landlady, who had nursed him, and who was 27 years his senior, by marrying her. She died at the end of three years, and Howard in 1756 embarked for Lisbon, with a view of doing something to alleviate the calamity of the great earthquake. On the voyage he was taken prisoner by a French privateer and carried into Brest, where he witnessed the inhuman treatment of prisoners of war. Having procured the exchange of himself and his fellow captives, he returned to England, married a second time in 1758, and settled upon an estate at Cardington, Bedfordshire, which he had inherited from his father. His career of active philanthropy may be said to date from this time. He built schools and model cottages for the peasantry, the latter the first erected in England for their benefit; and Cardington, formerly a wretched and filthy village, now attracted attention by its neatness and the healthful and thrifty appearance of its inhabitants. In 1765 his second wife died, and for several years he was employed in his studies and reformatory plans, and in travelling on the continent. He was named for the office of sheriff of Bedfordshire in his absence, and upon his return in 1773 accepted, and visited in his official capacity the Bedford jail, in which John Bunyan wrote his "Pilgrim's Progress." The wretched condition of the prisoners made a deep impression upon him; and the confinement of many innocent persons for months and sometimes for years, from in-

ability to pay their fees of jail delivery, so shocked him that he proposed to the magistrates to pay regular salaries to the jailers, in place of the fees collected from the prisoners. The magistrates, unprepared for such an innovation, asked for a precedent, and, in his fruitless exertions to find one, Howard visited every town in England containing a prison. He collected a mass of information respecting prison abuses, which he communicated in a report to the house of commons, who gave him a vote of thanks, and in 1774 passed bills "for the relief of acquitted prisoners in the matter of fees" and "for preserving the health of prisoners." At his own expense he caused copies of the new laws to be sent to every jailer in the kingdom. The prominence thus given to his name secured his election from Bedford to the house of commons; but his sympathy with the American revolution aroused the ministry to oppose him, and a parliamentary scrutiny unseated him. He never afterward participated in political life, but gave his whole time to the philanthropic plans in which he had embarked. He reexamined the principal penal establishments of England, and visited those of France, Germany, and the Low Countries; then made a new tour through England, examining the operation of the new jail act, and relieving much distress among poor debtors, and revisited a large portion of the continent. The result of these researches appeared in his "State of the Prisons in England and Wales, with Preliminary Observations and an Account of some Foreign Prisons" (4to, 1777). One of the first fruits of this publication was the determination of the ministry to make a trial of the discipline of hard labor in one of the large prisons. But as no building was adapted to the purpose, Howard undertook in 1778 another tour to collect plans and information, in the course of which he visited the Low Countries, Germany, Italy, and France, and travelled upward of 4,600 miles. In the succeeding year he made another survey of English prisons, and in 1780 published an appendix to his work. A bill, drafted by Sir William Blackstone and Mr. Eden, was now passed for building two penitentiaries on the hard labor system, of which Howard was appointed the first supervisor. To escape controversy as to the site of the buildings, he resigned his office, and between 1781 and 1784 travelled through Denmark, Sweden, Russia, Poland, Spain, and Portugal, publishing in 1784 a second appendix and a new edition of his work. His labors for a period of more than ten years had left him with impaired pecuniary resources and shattered health; but he embarked upon a second series of philanthropic researches with a zeal surpassing his physical powers, volunteering to procure for the British government information relating to quarantine establishments. The French government was incensed against him for having published in 1780 a translation of a suppressed French account of the interior of

the Bastille, and refused him a passport. He therefore travelled through the country in various disguises, and, after a series of romantic adventures and several narrow escapes from the police, who were constantly on his track, succeeded in visiting the new lazaretto at Marseilles. He proceeded thence to Malta, Zante, Smyrna, and Constantinople, fearlessly exposing his person in infected places. That he might speak with authority on the subject of pest houses, he went to Smyrna, sought out a foul ship, and sailed in her for Venice. After a voyage of 60 days, during which he assisted the crew in beating off an attack of pirates, he arrived at his destination and was subjected to a rigorous confinement in the Venetian lazaretto, under which his health suffered severely. He returned to England in February, 1787, after an absence of 16 months, and published his second great work, "An Account of the Principal Lazarettos of Europe, with various Papers relating to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and additional Remarks on the Present State of those in Great Britain and Ireland" (4to, 1789), in the preface to which he announced his intention to pursue his inquiries in the same direction, observing that his conduct was not from rashness or enthusiasm, but a serious conviction of duty. In the summer of 1789 he started on his last continental tour, meaning to pass through Russia to the East, but was cut off by camp fever which he contracted from a patient at Kherston, on the Black sea. He expended nearly the whole of his fortune in various benefactions. In his private relations he was pure-minded, pious, and upright.—See Hepworth Dixon's "Howard and the Prison World of Europe" (2d ed., London, 1850); also the memoirs by Dr. Aikin, J. B. Brown, the Rev. J. A. Field, and T. Taylor. A marble statue of him was erected in St. Paul's cathedral, London.

HOWARD, John Eager, an American revolutionary soldier, born in Baltimore co., Md., June 4, 1752, died Oct. 12, 1827. In 1776 he commanded a company in the flying camp under Gen. Mercer, which took part in the battle of White Plains. Upon the disbanding of his corps in 1776, he was commissioned major in the 4th Maryland regiment of the line, with which he took part in the battles of Germantown and Monmouth. In 1780, as lieutenant colonel of the 5th Maryland regiment, he fought at Camden under Gates (Aug. 16), and in the latter part of the year joined the army under Greene. In the battle of Cowpens, Jan. 17, 1781, he displayed great gallantry, and the bayonet charge of the Maryland troops under his command secured victory to the Americans. At one period of the day he held in his hands the swords of seven officers of the 71st British regiment who had surrendered to him. This was said to have been the first occasion in the war on which the bayonet was effectively used by the American troops. For his ser-

vices in this battle Col. Howard received from congress a silver medal. He fought at Guilford Court House (March 15), materially aiding Greene in effecting his retreat, and again at Hobkirk's Hill (April 25). After the latter battle he succeeded to the command of the 2d Maryland regiment. At Eutaw Springs (Sept. 8) his troops were so cut up that the command was reduced to Col. Howard, a single commissioned officer, and 30 men. With this small force he was returning to the charge when he was severely wounded. He was governor of Maryland from 1789 to 1792, United States senator from 1796 to 1803, and in 1798 was selected by Washington, in anticipation of war with France, for one of his brigadier generals. During the panic in Baltimore subsequent to the capture of Washington by the British troops in 1814, he was one of the most earnest opponents of the capitulation.

HOWARD, Oliver Otis, an American soldier, born at Leeds, Maine, Nov. 8, 1830. He graduated at Bowdoin college in 1850, and at West Point in 1854, and became instructor in mathematics there in 1857. He resigned his commission as first lieutenant June 4, 1861, to take command of a regiment of Maine volunteers. At the battle of Bull Run he commanded a brigade, and was made brigadier general of volunteers, Sept. 3. He was assigned to a brigade in the army of the Potomac, and in the battle of Fair Oaks, June 1, 1862, lost his right arm. After the battle of Antietam he took command of a division of the 2d corps, and at the battle of Chancellorsville he commanded the 11th corps. At Gettysburg, after the death of Reynolds, he commanded during the first day of the battle. He afterward received a commission as major general of volunteers, dating from Nov. 29, 1862. He was engaged at Lookout Valley, Oct. 29, 1863, at Chattanooga, Nov. 23-25, and in the operations for the relief of Knoxville in December. On July 27, 1864, he took command of the army of the Tennessee. He was in most of the battles of the Georgia campaign ending in the capture of Atlanta, and commanded the right wing of Sherman's army in its march to the sea and through the Carolinas. He was appointed a brigadier general in the regular army, his commission to date from Dec. 21, 1864; and brevet major general March 13, 1865. On May 12, 1865, he was appointed commissioner of the freedmen's bureau, and held that office until the closing of the bureau by law, June 30, 1872. He was made a trustee of Howard university March 19, 1867, president of that institution April 6, 1869, and resigned in 1873. He was appointed special commissioner to the Indians March 6, 1872, and spent eight months on that duty in New Mexico and Arizona. In March, 1874, he was tried by court martial on charges of pecuniary dishonesty in the management of the freedmen's bureau, and was acquitted.

HOWARD, Thomas, third duke of Norfolk, an English statesman, born about 1473, died

July 18, 1554. In 1513 he became high admiral of England, and in the same year aided his father in gaining the battle of Flodden field, for which he was created earl of Surrey. He afterward quelled an insurrection in Ireland under O'Neal, and one incited by the Catholics in the north of England. Though a staunch Catholic, he succeeded by his prudent conduct in disarming for a long time the suspicion and jealousy of Henry VIII., who however condemned to death his son, the accomplished earl of Surrey. The duke himself was finally condemned to be beheaded for treason; but the king dying before his execution, a respite was granted him, and he was kept a prisoner in the tower throughout the reign of Edward VI. On the accession of Mary in 1553 he was restored to his rank and property.

HOWARD, Thomas, earl of Arundel. See ARUNDEL.

HOWARD UNIVERSITY, an institution of learning in Washington, D. C., organized by a special act of congress in 1867, and named from Gen. O. O. Howard, one of its founders. It was designed to afford advanced instruction especially to colored students, but in the admissions no distinction is made as to color or sex, and among its instructors and students are white and colored persons of both sexes. The university grounds are near the head of Seventh street, where are grouped nine buildings, the chief of which is four stories high and contains rooms for lectures and recitations, a chapel, library, philosophical apparatus, museum, and offices. Miner hall is three stories high, with rooms for 100 young women, while Clark hall has accommodations for 200 male students. The general management of the institution is vested in a board of 21 trustees. The university comprises a normal department with a two years' course of study, including also, for younger students, the model school and the Miner school; the preparatory, with a course of three years; the collegiate, four years; the theological, two years; the law, two years; the medical, three years; and the military, commercial, and musical departments. An examination is required for admission to the collegiate department, and upon the completion of the course the degree of A. B. is conferred. Special efforts have been made to give the law department the most complete facilities for imparting a thorough legal education. From this school have graduated 49 young men and one young woman. The whole number of instructors connected with the university is 28, including 4 in the collegiate, 5 in the theological, 3 in the law, and 9 in the medical department. The number of students in 1872-'3 was 238 in the normal, 100 in the preparatory, 35 in the collegiate, 26 in the theological, 67 in the law, 45 in the medical, 84 in the commercial, and 21 in the musical department; total, after deducting repetitions, 567. About two thirds of the students are colored. Indigent students may be relieved from paying the tuition fee.

The university possesses a library of 7,500 volumes, a mineralogical cabinet, a museum of curiosities, and a picture gallery. Although the government of the United States aided in the establishment of the university, it is now dependent upon contributions and fees received from students. More than \$100,000 toward a proposed endowment of \$300,000 has been subscribed. Gen. Howard was president of the university until the latter part of 1873, when he resigned, and John M. Langston (colored), dean of the law department, was appointed vice president.

HOWE, the name of three British officers connected with American history, all of them sons of Emanuel Scrope Howe, Viscount Howe in the peerage of Ireland. **I. George Augustus**, general, born in 1724, killed at Ticonderoga, July 8, 1758. In 1757 he was sent to America in command of the 60th regiment, and arrived at Halifax in July. On Sept. 28 he was put in command of the 55th foot, and on Dec. 29 was made brigadier general. On July 6, 1758, he landed under Abercrombie at the outlet of Lake George. Coming suddenly upon a French force, he fell in the ensuing skirmish. The general court of Massachusetts appropriated £250 for a monument to him, which was erected in Westminster abbey. **II. Richard**, admiral, born in London in 1725, died there, Aug. 5, 1799. He entered the navy at the age of 14, and served with distinction against the French from 1745 to 1759. After the conclusion of peace he obtained a seat at the admiralty board. In 1765 he was appointed treasurer of the navy, and entered parliament for Dartmouth. Five years later he was made rear admiral of the blue, and commanded a fleet in the Mediterranean. In 1776 he sailed for North America with the rank of vice admiral of the blue, and as joint commissioner with his brother William for restoring peace. He was variously employed against the American forces for two years, and in August, 1778, had an indecisive encounter with a superior French fleet under Count d'Estaing, off the coast of Rhode Island, both fleets being much shattered by a severe storm. In April, 1782, he was made a peer of Great Britain, under the title of Viscount Howe, having since 1758 borne the Irish title of the same grade, inherited from his brother George. In the latter part of 1782 he succeeded in bringing into the harbor of Gibraltar the fleet sent to the relief of Genl. Elliott, then besieged there by the combined French and Spanish forces. For these and previous services he was in August, 1788, created Earl and Baron Howe of Langar. In 1793 he was put in command of the channel fleet. On June 1, 1794, he gained a victory over the French off the western coast of France, and received the thanks of parliament. In the succeeding year he was made admiral of the fleet, and in 1797 a knight of the garter. His last important service was the suppression of the mutiny in the fleet at Spithead in 1797. His memoirs were

compiled by Sir John Barrow (London, 1838).

III. William, general, born Aug. 10, 1729, died July 12, 1814. He commanded the light infantry under Wolfe in the battle on the heights of Abraham, near Quebec (1759), and in 1775 succeeded Gen. Gage as commander of the British forces in America. He commanded at the battle of Bunker Hill, and after the evacuation of Boston retired to Halifax. Subsequently he defeated the Americans on Long Island, Aug. 27, 1776, took possession of New York, Sept. 15, directed the movements in the Jerseys and in Pennsylvania, and repelled the American attack at Germantown, Oct. 4, 1777. He was succeeded by Sir Henry Clinton in May, 1778. His conduct was severely criticised, but an investigation ordered by parliament in 1779 freed him from blame. He succeeded his brother Richard in the Irish viscounty, and at the time of his death was a privy councillor and governor of Plymouth.

HOWE, Elias, an American inventor, born in Spencer, Mass., July 9, 1819, died in Brooklyn, N. Y., Oct. 3, 1867. He lived with his father, who was both farmer and miller, till 1835, working upon the farm and in the mill, and attending the district school during the winters. He then went to Lowell, and was employed in a manufactory of cotton machinery, and afterward worked in a machine shop in Boston. Here he developed his invention of the sewing machine, completing his first machine in May, 1845, and securing a patent Sept. 10, 1846. After constructing four machines in the United States, he visited England in 1847, and remained two years. He returned to Boston entirely destitute, and resumed his trade. From this period till 1854 he was involved in expensive lawsuits, when the principal infringers of his patents acknowledged his rights, and arranged to manufacture sewing machines under licenses from him. His income now steadily increased, reaching \$200,000; and his fortune realized from his invention is said to have amounted to \$2,000,000. During the civil war he enlisted as a private in a Connecticut regiment, and when the payment of the regiment was delayed by the government, he advanced the necessary money. (See SEWING MACHINE.)

HOWE, John, an English clergyman, born at Loughborough, Leicestershire, May 17, 1630, died in London, April 2, 1705. He graduated at Christ's college, Cambridge, became pastor of a nonconformist church in Great Torrington, and was selected by Cromwell in 1657 for his domestic chaplain. After the restoration and the act of uniformity he led a wandering life, and continued to preach in private houses. He passed five years in Ireland, where he was chaplain to Lord Massarene in the parish of Antrim, was pastor of a congregation in London from 1675 to 1684, travelled on the continent with Lord Wharton in 1685, became pastor of the English church at Utrecht, and returned to England in 1687, when James II. published his declaration for liberty of con-

science. A complete edition of his works, with a life by the Rev. John Hunt, appeared in London in 8 vols. (1810-'22; new ed., 1868), and with a life by Edmund Calamy in 1 vol. (1838). A biography, by Henry Rogers, was published in 1836.

HOWE. I. Samuel Gridley, an American philanthropist, born in Boston, Nov. 10, 1801. He studied in the Boston grammar school, thence went to Brown university, where he graduated in 1821, and studied medicine in Boston. In 1824 he went to Greece, and served as a surgeon in the patriot army and in various other capacities till 1830. In 1831 he returned to the United States, and soon became interested in the project for establishing an institution for the blind in Boston. He accepted the charge of it, and embarked at once for Europe, to acquire the necessary information and engage teachers, visiting the schools of France and England for this purpose. While in Paris he was made president of the Polish committee, and undertook to carry and distribute funds for the relief of the detachment of the Polish army which had crossed into Prussia. In the discharge of this duty he was arrested and imprisoned for about six weeks by the Prussian government. He was then liberated, and escorted over the French frontier by night. In 1832 the Perkins institution for the blind, in Boston, was put in operation under his charge. A notable achievement in this institution is the education of Laura Bridgman, a blind deaf mute. (See BRIDGMAN, LAURA.) He took a prominent part in founding the experimental school for the training of idiots, which resulted in the organization, in 1851, of the Massachusetts school for idiotic and feeble-minded youth. He was actively engaged in the anti-slavery movement, and was a free-soil candidate for congress from Boston in 1846. He engaged earnestly in the sanitary movement in behalf of the soldiers during the civil war. In 1867 he again went to Greece as bearer of supplies for the Cretans in their struggle with the Turks, and subsequently edited in Boston "The Cretan." In 1871 he was one of the commissioners to visit Santo Domingo and report upon the question of the annexation of that island to the United States, of which he has since been an earnest advocate. He has published a "Historical Sketch of the Greek Revolution" (1828), and a "Reader for the Blind," in raised characters (1839). **II. Julia Ward**, an American poetess, wife of the preceding, born in New York, May 27, 1819. Her early education comprised an unusually wide range of studies. In 1843 she was married to Dr. Howe, with whom she made a tour in Europe. In 1850 she again went to Europe, being absent more than a year, a great part of the time in Rome. After her return she published "Passion Flowers," a volume of poems (1854); "The World's Own," a drama (1855); "Words for the Hour" (1856); "Lenore," a tragedy (1857); and "Hippolytus," a tragedy (1858).

During the winter of 1858-'9 she visited Cuba, and in 1860 published "A Trip to Cuba." A volume of poems, "Later Lyrics," appeared in 1866. In 1867 she accompanied her husband to Greece, and published "From the Oak to the Olive" (1868). She is a prominent speaker in behalf of woman's rights.

HOWELL, a S. county of Missouri, bordering on Arkansas, and drained by Spring river and affluents of the N. fork of the White; area, about 900 sq. m.; pop. in 1870, 4,218, of whom 24 were colored. The surface is hilly, and the soil in the valleys fertile. There are large forests of pine. The chief productions in 1870 were 15,356 bushels of wheat, 115,728 of Indian corn, and 8,454 of oats. There were 1,132 horses, 3,201 cattle, 2,707 sheep, and 5,656 swine. Capital, West Plains.

HOWELL, James, an English author, born near Brecknock, Wales, in 1596, died in 1666. He was educated at Jesus college, Oxford, and passed many years on the continent, as a mercantile agent, as travelling tutor, or in a diplomatic capacity. In 1640 he was appointed clerk to the council at Whitehall, but after the breaking out of the civil war he was thrown into the Fleet, where he languished until after the death of Charles I. After the restoration he was appointed historiographer royal, an office which he retained until his death. Howell's publications number about 40, the greater part as well as the best of them being in prose. His *Epistolæ Ho-Eliañæ*, or "Familiar Letters," first printed in 1645-'55, and of which many editions have appeared, was the second published collection of epistolary literature in the English language.

HOWELLS, William Dean, an American author, born in Martinsville, Belmont co., Ohio, March 1, 1837. He learned the printing business in his father's office, and worked at that trade for 12 years. He then became connected with the "Ohio State Journal" as assistant editor, and up to 1860 had published six poems in the "Atlantic Monthly," besides a life of Abraham Lincoln, and, with John J. Piatt, a volume of verse called "Poems of Two Friends." He was appointed by President Lincoln United States consul at Venice, where he remained till 1865. On his return home he joined the staff of the "Nation," and shortly after became assistant editor of the "Atlantic," which magazine passed into his sole control as editor in July, 1871. His publications are: "Venetian Life" (London and New York, 1866); "Italian Journeys" (1867); "No Love Lost," a poem (1868); "Suburban Sketches" (1869); "Their Wedding Journey" (1872); and "A Chance Acquaintance" (1873).

HOWITT. I. William, an English author, born at Heanor, Derbyshire, in 1795. His parents were members of the society of Friends, and in 1823 he married Mary Botham, also a member of the society. They made a pedestrian excursion through Great Britain, and subsequently embarked in literature, writing

several books in common, the first being "The Forest Minstrel and other Poems" (1823). In 1840 he went to Heidelberg for the education of his children. In 1847 he established "Howitt's Journal," which was published only a short time. In 1852-'4 he was engaged in gold mining in Australia. His principal works are: "Book of the Seasons" (1831); "Popular History of Priestcraft" (1834); "Rural Life of England" (1837); "Colonization and Christianity" (1838); "Boy's Country Book" (1839); "Visits to Remarkable Places" (1839); "Student Life of Germany" (1841); "Rural and Domestic Life of Germany" (1842); "Jack of the Mill" (1844); "The Aristocracy of England" (1846); "Homes and Haunts of the British Poets" (1847); "The Year Book of the Country" (1847); "The Hall and the Hamlet" (1847); "Stories of English Life" (1853); "Natural History of Magic" (1854); "Land, Labor, and Gold" (1855); "The Man of the People" (1860); "Illustrated History of England" (1861); "The Ruined Castles and Abbeys of Great Britain" (1861); "History of the Supernatural in all Ages and Nations" (1863); "Discoveries in Australia" (1865); and "The Mad War Planet, and other Poems" (1871). **II. Mary Botham**, an English authoress, wife of the preceding, born at Uttoxeter about 1804. She is joint author with her husband of several of the books above mentioned. Among her numerous separate publications are the novels "Wood Leighton" (1836) and "The Heir of West Wayland" (1851). She has written many volumes, in prose and verse, designed for the young, and has made numerous translations from the Swedish of Fredrika Bremer, the Danish of Andersen, and the German of various authors. Her later works are: "Biographical Sketches of the Queens of England" (1862); "The Cost of Caergwyn" (1864); "Birds and their Nests" (1871); and "A Pleasant Life" (1871).—**ANNA MARY**, daughter of the preceding, married in 1859 to Mr. A. A. Watts, has published "An Art Student in Munich" (1853), and "The School of Life" (1857). Her sister **MARGARET** has published "Twelve Months with Fredrika Bremer in Sweden" (2 vols., 1866).

HOWITZER. See **ARTILLERY**, vol. i., p. 786.

HOWSON, John Saul, an English clergyman, born in 1816. He graduated at Trinity college, Cambridge, a double first, in 1837, and in each of the next three years obtained a prize for an essay. In 1845 he took orders and became senior classical master in Liverpool college, of which he was principal from 1849 to 1865. In 1866 he was made vicar of Wisbeach, Cambridgeshire, and in 1867 dean of Chester. He has made numerous contributions to Biblical literature, his principal publication being "The Life and Epistles of St. Paul" (2 vols. 4to, 1850-'52), which he wrote conjointly with the Rev. W. J. Conybeare, furnishing the historical, geographical, and descriptive matter. He has also published

"The Character of St. Paul" (1864) and "Metaphors of St. Paul" (1868).

HOWTH, Hill of, a peninsula of Ireland, county Dublin, forming the N. boundary of Dublin bay. It is a rocky and picturesque elevation, rising to the height of 563 ft., 3 m. long and 2 m. broad, having at its extremity a lighthouse. Howth gives the title of earl to the family of St. Lawrence, the descendants of its Anglo-Norman conquerors. A harbor of 52 acres has been formed at Howth, costing £500,000.

HÖXTER, a town of Prussia, in the province of Westphalia, on the Weser, crossed here by a stone bridge, 28 m. E. N. E. of Paderborn; pop. in 1871, 5,041. It is a thriving manufacturing and commercial place, and paper, cotton goods, and linen are made. Höxter was formerly the capital of the ecclesiastical principality of Korvei, and belonged to the Hanseatic league. It abounds with reminiscences of the battles of Charlemagne against the Saxons, and the watch tower on the neighboring Brunsberg is according to some traditions the relic of a formidable Saxon fortress built by Bruno, brother of Wittikind. The town endured many military vicissitudes during the 17th century.

HOYLE, Edmund, an English writer on games, born in 1672, died in 1769. So generally is his principal work accepted as authority in card playing, that "according to Hoyle" has become a proverb. There have been many editions of his book, among which are "Hoyle's Games, Improved and Enlarged by G. H." (London, 1853); "Hoyle's Games made Familiar" (London, 1855); and "Hoyle's Games, containing the Rules for playing Fashionable Games" (Philadelphia, 1859).

HRABANUS MAURUS. See **RABANUS**.

HUACA, a Peruvian word, signifying something sacred, applied particularly to sepulchral mounds. Among the Peruvians all persons remarkable for their inventions, or for having in any way ameliorated the condition of mankind, were the recipients of a kind of hero worship. Few had temples, their shrines being generally their tombs, called *huacas*. The Peruvians made sacrifices to the huacas, which were supposed to respond to petitions and questions supported by appropriate offerings made in a proper spirit. The inner chambers of these oracular tombs were sometimes inhabited by priests; and generally they seem to have been devices whereby an inferior class of priests obtained their support. Some were of great extent, and erected over the remains of the incas, who were entitled to divine honors after death, and over the chiefs of provinces. In accordance with an invariable custom, the wealth of these high personages was buried with them. The violation of their tombs was commenced soon after the conquest, and from some of them vast treasures were taken. A single huaca among the ruins of Chimu, near the port of Trujillo in Peru, opened in 1563 by Garcia Gutierrez, afforded so large a treasure of gold and silver, that he paid 85,547 castellanos of

gold, as the royal fifth, into the treasury of Trujillo. But he did not obtain the whole of it, for in 1592 it was again opened, and 47,020 castellanos of gold were paid into the treasury as the royal fifth. So it seems that not less than 677,600 castellanos of gold, equal to \$931,000, were taken from this single tomb. The name *huaca*, as applied to aboriginal graves, gradually became extended to the provinces adjacent to Peru on the north, where they were also found to contain more or less of treasure. The name has also been applied to Indian graves in the district of Chiriqui in Colombia, whence many golden ornaments and images have been extracted.

HUALLAGA, a river of Peru, rising on the E. slope of the Eastern Cordillera, about lat. 10° S. and lon. 75° 30' W., flowing N. W. parallel to that range as far as lat. 8°, where it curves to the N. E., and joining the *Marañon* or Upper Amazon at La Laguna, lat. 4° 50' S. and lon. 75° 40' W., after a tortuous course of some 600 m., mainly through the Pampa de Sacramento, a region of which little is definitely known. For 60 m. from its mouth the Huallaga is navigable by the largest vessels; above that point rapids occur at intervals of about 50 m., but these do not impede the passage of canoes, especially in the upper portion of the river.

HUAMANGA. See AYACUCHO.

HUANGAVELICA. **I.** An inland department of Peru, occupying a portion of the valley bordered by the Eastern and Western Cordilleras S. E. of the department of Lima. The surface is intersected by numerous hills, and watered by the Jauja and other rivers, and numerous lakes. The climate is mostly very cold, and the soil rather inferior to that of other parts of the republic. There being no forests, wood is scarce, and the chief combustible used is a species of grass called *ichu*. Gold is found, silver is abundant, and there is some copper; but the principal mineral product is mercury, especially that from the mine in the Cerro de Santa Barbara, discovered in 1563, the mean annual yield of which for 200 years was from 400,000 to 600,000 lbs. Large numbers of cattle, sheep, and llamas are reared, and wool of excellent quality is exported. **II.** A city, capital of the department, and of a province of the same name, 150 m. S. E. of Lima; pop. about 8,000. The streets are regular, and the houses solidly constructed of stone; several stone bridges cross the streams intersecting the town. Owing to the elevation, 12,670 ft. above the sea, the climate is very cold, and the town is exposed to fierce tempests, thunder, hail, and frost. Husbandry, cattle rearing, and mining are the chief occupations. In the immediate vicinity are numerous mercury furnaces; and excellent colors are extracted from a peculiar species of metalliferous clay which abounds in the neighborhood.

HUANTA, a town of Peru, in the department of Ayacucho, 205 m. S. E. of Lima; pop.

about 5,000. It is in a very picturesque and fertile region, is well built of stone, and has a large trade in cattle, sheep, grain, fruit, coca, dragon's blood, cinnamon, honey, &c.

HUANUCO. **I.** An inland department of Peru, occupying a portion of the valley bordered by the Eastern and Western Cordilleras, N. of the department of Lima. The surface is irregular, being intersected by hills mostly densely wooded, and delightful vales, watered by the Huallaga, Jauja, and numerous minor streams. The climate, hot in the low and cold in the elevated regions, is very salubrious, and the soil is extremely fertile and well cultivated. Precious woods, particularly cedar, and coca leaves are important articles of commerce. The sugar cane thrives well, and sugar is manufactured in several places; and coffee of superior quality is grown. The plains, though of inconsiderable extent, afford good pasturage for large herds of cattle and sheep; and the horses of Concepcion are highly esteemed. The district of Cerro de Pasco, formerly the capital of the department, has long been celebrated as the principal mining region of Peru. There are weaving factories at Tarma and elsewhere. Ruins of towns, temples, palaces, and fortresses, in various parts of the department, attest the opulence and civilization of the ancient Incas, once the exclusive lords of the soil. **II.** A city, capital of the department, and of a province and district of the same name, near the river Huallaga, 165 m. N. N. E. of Lima; pop. about 7,000. The only objects of interest still remaining in this once flourishing city are the ruins of edifices attesting its early splendor, and particularly a palace and temple of the sun, built by the Incas. Besides mining and agriculture, the manufacture of sweetmeats, much prized in Lima, occupies many of the inhabitants. It was founded in 1539 by Gomez Alvarado, who named it Leon de los Caballeros.

HUARAZ, an inland city of Peru, capital of the department of Ancachs, and of a district of its own name, 192 m. N. N. W. of Lima; pop. about 6,000. It is situated in the valley of Huaraz, one of the most fertile in the republic, and derives its importance from the large quantities of wheat and other grains, sugar, fruit, and cattle which it exports. Wood is here extremely scarce, and in its stead a species of peat called *champa* is used for fuel. The mineral productions, including gold, silver, and copper, are of considerable value. A railway is in course of construction (1874) from Huaraz to Chimbote, 172 m.

HUASTECAS. See QUETZALCOATL.

HUBBARD, William, an American historian, born in England in 1621, died in Ipswich, Mass., Sept. 14, 1704. He graduated at Harvard college in 1642, and was ordained in 1658 as minister at Ipswich, where he continued during the remainder of his life. In 1688 he was temporary rector or president of Harvard college. He is the author of "A Narra-

tive of the Troubles with the Indians from 1607 to 1677, with a Discourse" (4to, Boston, 1677), the map accompanying which is supposed to be the first executed in America, and "Memoir of Gen. Denison" (1684). He left also in manuscript a general history of New England, for which the colony paid him £50. For the most of the earlier annals he was indebted to Winthrop's MS. journal, and his MS. has been used by other historians and annalists. It was published by the Massachusetts historical society in 1815 (8vo, Cambridge).

HUBBARDTON, a town of Rutland co., Vermont, 48 m. S. W. of Montpelier; pop. in 1870, 606. It is noted for a battle between the British and Americans, July 7, 1777. The American army under Gen. St. Clair having been forced to evacuate Ticonderoga, July 6, their main body marched through Hubbardton to Castleton, leaving a rear guard of 1,000 half equipped men under Cols. Warner, Francis, and Haile, to wait at Hubbardton for the stragglers. Here on the following morning they were overtaken by about double their number of British, commanded by Gen. Fraser. The battle began at 7 A. M. The charge of the Americans at first forced the enemy to give way, but they soon formed again, while at the same time Col. Francis was mortally wounded, his men fell back, and Gen. Riedesel appeared on the field with a heavy reinforcement for the British. Warner was obliged to retreat, leaving 30 of his men killed and 294 wounded and prisoners, while the British acknowledged a loss of 183 killed and wounded, though, according to Ethan Allen, they lost 300. Col. Haile withdrew from the field with 300 men without coming into action. He demanded a court martial to investigate the charge of cowardice brought against him, but died in captivity before it could be held. A monument on the battle field was inaugurated July 7, 1859.

HUBER, François, a Swiss naturalist, born in Geneva, July 2, 1750, died in Lausanne, Dec. 21, 1831. At 15 years of age a too close devotion to the study of the natural sciences, which he had followed from childhood, affected his health and eyesight, and he was taken to Paris for medical treatment. His health was soon restored, but the disease of his eyes was pronounced incurable, and he soon after became totally blind. Before that time he had won the affections of a young lady, Mlle. Lullin, who married him, and until the close of his life was unremitting in her devotion to him. Being left by his father in comfortable circumstances, he resumed his investigations in natural science, in which he was aided by his wife, and a faithful attendant named Burnens, who ultimately became his reader and amanuensis. He had previously given much attention to the habits of bees, and believing that many of the statements of Réaumur and Bonnet on the subject were erroneous, he proceeded, with the assistance of his wife and attendant, to make a vast number of original

observations, which, having been digested and systematically arranged by him, were first published in his *Lettres à Ch. Bonnet* (1792). The work was reprinted in 1796, and again in 1814, under the title of *Nouvelles observations sur les abeilles*, both times with important additions. The last edition contained his *Mémoire sur l'origine de la cire*, in preparing which he was assisted by his son Pierre. The impregnation of the queen bee, and many other important facts in the economy of the beehive, were first made known in this work, which from its intrinsic merits, as well as the unusual circumstances under which it was prepared, made Huber's name famous throughout Europe. Subsequently, with the coöperation of Senebier, he produced a *Mémoire sur l'influence de l'air et des diverses substances gazeuses dans la germination des différentes plantes* (Geneva, 1801).—**PIERRE**, his son, born in Geneva in 1777, was the author of several valuable papers relating to bees and butterflies, and published *Recherches sur les fourmis indigènes* (1810). He died at Yverdun in 1840.

HUBER, Jean Rodolphe, a Swiss painter, born in Basel in 1668, died in 1748. He studied in Switzerland and in Italy, and executed works for various German princes, including historical pictures for the palace of the duke of Würtemberg at Stuttgart. He excelled in correctness of drawing and vigorous coloring, and on account of his surprising facility in portrait painting was called the Tintoretto of Switzerland, though greatly inferior to that master.

HUBER, Johann Nepomuk, a German theologian, born in Munich, Aug. 18, 1830. He graduated at the university of Munich in 1854, and became professor in 1859. His *Philosophie der Kirchenväter* (Munich, 1859) was in 1860 placed on the prohibitory index, and an effort was made to prevent students from attending his lectures. His rupture with the ultramontanes became still wider in 1863, when in an assembly of Roman Catholic scholars he stood alone in asserting the right of free investigation in theology. In 1871 he became the foremost adversary of the society of Jesus, and one of the principal leaders of the Old Catholic movement in Bavaria, in opposition to the papal decree of infallibility. His works include *Johann Scotus Erigena* (Munich, 1859); *Idee der Unsterblichkeit* (1861); *Die Proletarier* (1864); *Professor Stöckl in Münster*, and *Offener Brief an Professor Stöckl*, exposing the pantheism of Thomas Aquinas (1864); *Studien* (1867); *Freiheiten der französischen Kirche* (1870); *Das Papstthum und der Staat* (1870); *Die Lehre Darwins kritisch betrachtet* (1870); and *Kleine Schriften* (1871).

HUBER, Marie, a Swiss authoress, born in Geneva in 1695, died in Lyons, June 13, 1753. She was the daughter of a merchant, received a scientific education, never married, and spent her whole life in seclusion, study, and charitable labor. Her principal works are: *Systèmes des théologiens anciens et modernes conciliés*

(Geneva, 1731; enlarged ed., 1739); and *Lettres sur la religion essentielle à l'homme* (1739; new ed., enlarged, 6 vols., 1754).

HUBER. I. Michael, a German scholar, born at Frontenhausen, Bavaria, in 1727, died in Leipsic, April 15, 1804. He resided in Paris for several years, and went to Leipsic in 1766, where he became a teacher of the French language. He translated into French many poems of Klopstock, Wieland, Lessing, and others (*Choix de poésies allemandes*, 4 vols., Paris, 1766), and other works, among which is Winckelmann's *Kunstgeschichte* (3 vols., Leipsic, 1781), and wrote *Notices générales des graveurs et des peintres* (Dresden, 1787). **II. Ludwig Ferdinand**, son of the preceding, born in Paris in 1764, died near Leipsic, Dec. 24, 1804. In 1798 he became editor of the *Allgemeine Zeitung* in Stuttgart. He translated dramas from the English and French, and wrote a number of plays and collections of tales. He also published *Friedenspräliminarien* (10 vols., Berlin, 1793-'6). A collection of his later works was published by his widow (4 vols., Tübingen, 1806-'19). **III. Therese**, wife of the preceding, born in Göttingen, May 7, 1764, died in Augsburg, June 15, 1829. She was a daughter of Heyne, and was first married to the traveller Johann Georg Forster, and afterward in 1794 to Huber, under whose name many of her writings were published. In 1819 she became editor of the *Morgenblatt* at Stuttgart, and published *Forster's Briefwechsel* with a biographical sketch (2 vols., Leipsic, 1828-'9). A collection of her *Erzählungen* was published by her son (6 vols., Leipsic, 1830-'33). **IV. Victor Aimé**, son of the preceding, born in Stuttgart, March 10, 1800, died at Wernigerode, July 19, 1869. He studied medicine, travelled extensively, and was professor in various places, lastly in 1843 of languages and literature at Berlin, retiring in 1850. As a publicist he opposed the revolutionary movements of 1846-'9, but subsequently left the ranks of the ultra conservatives. His later writings embrace popular politico-economical subjects, but his reputation rests mainly on his works relating to the English and Spanish languages and literature. The more celebrated of them, besides those treating of the history of the Cid, are: *Skizzen aus Spanien* (4 vols., Göttingen, 1828-'35); *Die neuromantische Poesie in Frankreich* (Leipsic, 1833); *Die englischen Universitäten* (2 vols., Cassel, 1839-'40); and *Reisebriefe aus Belgien, Frankreich und England* (2 vols., Hamburg, 1855). His biography by Elvers was published in 1872.

HÜBNER, Karl, a German painter, born in Königsberg, June 14, 1814. He is a disciple of the Düsseldorf school, and excels in *genre* pictures. In 1864 he was appointed professor at Düsseldorf. Many of his works have been brought to the United States.

HÜBNER, Rudolf Julius Benno, a German historical painter, born in Prussian Silesia in 1806. He studied in Berlin under Schadow, and fol-

lowed his master to Düsseldorf. Among his earlier works were illustrations of Goethe's ballad of the "Fisherman," and "Orlando delivering Isabella," a scene in Ariosto's epic. He has also gained reputation as a painter of cartoons and portraits. He became a resident of Dresden in 1839, and professor at the academy there in 1841. He sent to the universal exposition of 1867 a historical painting of the "Discussion between Luther and Eck," and two religious paintings, "Jesus at the Age of twelve," and the "Magdalen by the Body of Christ."

HUC, Évariste Régis, a French missionary and traveller, born in Toulouse, Aug. 1, 1813, died in Paris, March 31, 1860. He studied theology in his native city, and taught in the seminary there for a while, after which he entered the order of Lazarists, and was ordained priest in Paris in 1839. Resolving to devote himself to the Chinese missions, he set sail from Havre a few days after his ordination, and reached Macao about the month of August. He passed 18 months in the Lazarist seminary at this place, preparing himself for the work he was about to undertake, and in the early part of 1840, shaving his head with the exception of the queue which he had carefully cultivated since his arrival, dyeing his skin, and putting on the Chinese costume, he started from Canton for the interior of the empire. After directing a Christian mission in the southern provinces, he went to Peking, where he perfected himself in the Chinese language, and subsequently established himself at He-Shuy (valley of Black Waters), in Mongolia, just north of the great wall and not far from Peking, where there was a considerable population of Chinese Christians. He visited various parts of Mongolia, acquiring the dialect of the country, and translating into Mongol several books of prayer and instruction. In 1844 the vicar apostolic of Mongolia directed M. Huc and another French Lazarist, Joseph Gabet, to make a journey through the vicariate, for the purpose of ascertaining its extent and studying the character and manners of the Tartars. Adopting the costume of the Thibetan lamas or priests, and accompanied by a young lama convert, named Samdadshiamba, they set out in September, travelling S. W. along the Mongolian side of the great wall. Their caravan consisted of a horse, a mule, and three camels. Their only guides were a map and a compass. At night they slept in tents, and their food during 18 months was generally confined to tea and a little meal. After a few days' journey they arrived at the city of Tolon-noor, where they completed their outfit. At the large new town of Shagan-kooen they crossed the Hoang-ho river and entered the sandy steppes of the Ortoos country, where they suffered for want of water and forage. Crossing the Hoang-ho again with great difficulty at a season of inundation, they entered the N. E. part of the Chinese province of Kansu in the early part of November, and remained two days at a frontier

town. In January, 1845, they reached Tangkiul, on the boundary between Kansu and the territory of Koko-nor. From Lassa, the capital of Thibet, their point of destination, they were yet distant four months' journey across a desert utterly uninhabited except by robbers. They consequently resolved to wait here eight months for the arrival of a Thibetan embassy on its way home from Peking, under whose escort they might travel in safety. During their stay they studied the Thibetan language and Buddhist books with the assistance of a teacher, and after a while they were invited to take up their abode in the famous lamasery of Koonboom, about 30 m. distant. In this establishment, which numbers about 4,000 lamas, they remained three months, treated, as they were in all parts of Mongolia, with great kindness. At the end of that time they removed to Chogortan, a summer establishment belonging to the lamasery. Toward the end of September the embassy arrived, and the missionaries joined the caravan, which consisted of 2,000 men and 3,700 animals. In crossing the desert and climbing the snow-covered mountains over which their route led them, they suffered the most terrible hardships. M. Gabet fell ill and was every moment expected to die, but they were obliged to press on with the sick man fastened to his camel. On Jan. 29, 1846, they entered Lassa. After a few days they were summoned before the *kalon* or regent, the real ruler of the country under the nominal supremacy of the grand lama, who received them well, gave them a residence of his own, and allowed them to preach and set up a little chapel. The Chinese ambassador, Keshen, who had conducted the negotiations with the British at Canton in 1840-41, soon interposed on political grounds, and they were sent to Chingtoofoo, capital of the Chinese province of Sechuen, and their neophyte Samdadshiembra back to his own country. MM. Huc and Gabet left Lassa March 15, and travelled in palanquins with great state, having a mandarin and a body of soldiers for escort. They wore the richest Chinese robes, and insisted upon putting on the yellow cap and red girdle reserved for members of the imperial family. These precautions secured respectful treatment throughout their journey. Their expenses were defrayed by government. At Chingtoofoo they were put on trial, and it was resolved to send them to Canton. The journey was performed in the same state, sometimes overland, sometimes on the Yangtse-kiang and other navigable rivers. In October, 1846, they arrived at Canton, and soon went to the Lazarist seminary at Macao. Here M. Huc remained between two and three years, arranging for publication his notes of travel. M. Gabet returned to Europe in November, and thence proceeded to South America, where he died soon afterward at Rio de Janeiro. In 1849 M. Huc set out for Peking, intending to revisit the missions in Mongolia; but an inundation

obliged him to remain six months at a Christian station in the province of Chekiang, and shortly after his arrival at the capital the shattered state of his health induced him to return home. He sailed from Macao Jan. 1, 1852, visited Ceylon, India, Egypt, Palestine, and Syria, and landed at Marseilles in June of the same year. He subsequently fixed his residence in Paris. His *Souvenirs d'un voyage dans la Tartarie, le Thibet et la Chine* appeared in 1852 (2 vols. 8vo, Paris), and was translated into English by William Hazlitt (London, 1852). This work is not only one of the most interesting books of travel which have been written during the present generation, but is stored with valuable information with regard to the history, inhabitants, and geography of the previously almost unknown region of Mongolia. *L'Empire chinois* (2 vols. 8vo, 1854; English translation, London, 1855) relates the adventures of the missionaries during their journey from Lassa to Canton; it is written in an attractive style, enlivened with much humor, and a large part of it is devoted to a general account of the manners, customs, government, laws, and internal condition of the Chinese empire. He also wrote *Le Christianisme en Chine, en Tartarie et au Thibet* (4 vols., 1857-'8; translated into English, 3 vols.).

HUCKLEBERRY. See WHORTLEBERRY.

HUDDERSFIELD, a market town and parliamentary borough of England, in the West riding of Yorkshire, on the Colne, 35 m. S. W. of York, and 204 m. by railway N. N. W. of London; pop. in 1871, of the borough, 70,253, of the town, 38,658. There are in the town 34 places of worship, of which 9 belong to the established church, 5 to the Congregationalists, and 14 to the Methodists. There are two colleges, a philosophical hall, and a mechanics' institute. It is connected by canals with the Mersey and the Humber. It is one of the chief seats of the woollen manufacture in England, of which nearly every variety is produced. It has an extensive cloth hall, where a fair is held each Tuesday attended by upward of 600 manufacturers. There are also cotton mills, breweries, chemical works, and dye houses.

HUDSON, a N. E. county of New Jersey, bounded E. by the Hudson river and New York bay, S. by the Kills, separating it from Staten island, S. W. and W. by Passaic river and Newark bay, and N. W. by the Hackensack, which also intersects the S. W. part; area, 75 sq. m.; pop. in 1870, 129,067. It has a diversified surface, rising into hills on each side of the Hackensack. Limestone, copper, and magnetic iron ore are found. The Morris canal passes through it, and numerous railroads radiate from Jersey City and Hoboken. The value of farms in 1870 was \$3,134,000; of farm productions, chiefly market vegetables, \$312,920. There were 333 manufacturing establishments, with an aggregate capital of \$3,280,526, and an annual product of \$24,256,017. The most important were 1 manufactory of boxes,

19 of bread, &c., 1 of cars, 25 of clothing, 1 of cooperage, 3 of crucibles, 2 of drugs and chemicals, 1 of feathers, 3 of gas, 1 of heating apparatus, 1 of India-rubber goods, 11 of iron, 3 of jewelry, 11 of machinery, 5 of marble and stone work, 2 of molasses and sirup, 4 of oakum, 1 of castor oil, 2 of paints, 2 of paper, 1 of polishing preparations, 3 of silk goods, 4 of soap and candles, 3 of steel, 8 of tin, copper, and sheet-iron ware, 37 of cigars, 1 of watches, 1 flour mill, 4 breweries, 2 saw mills, and 4 pork-packing establishments. Capital, Jersey City.

HUDSON, a city and the capital of Columbia co., New York, situated on the E. or left bank of the Hudson river, at the head of ship navigation, 116 m. above New York city and 29 m. below Albany; pop. in 1850, 6,280; in 1860, 7,187; in 1870, 8,615. It is beautifully situated on rising ground, and presents a highly picturesque appearance, especially when seen from the river at a distance. A slate bluff rises abruptly from the water to a height of 60 ft., whence a ridge slopes upward for $1\frac{1}{2}$ m., terminating in Prospect hill, 500 ft. above the river. The principal street runs along this ridge, from Prospect hill to a public square laid out on the summit of the bluff. The city is divided into four wards, and is regularly laid out, with streets crossing each other at right angles. The principal public buildings are the court house, a handsome marble and limestone building, 116 ft. long and 60 ft. high, surmounted by a dome and faced by an Ionic portico, and the city hall, a brick edifice, containing the post office. Hudson is a terminus of the Hudson and Boston railroad, and an important station on the Hudson River railroad. It has regular steamboat communication with Albany and New York; and from Athens on the opposite bank of the river, with which it is connected by a steam ferry, a branch of the New York Central railroad extends to Schenectady. The wharves are built on two bays at either side of the public square, and are accessible by large ships. It is said that at one time Hudson owned a larger amount of shipping than New York. It was made a port of entry in 1795, had an extensive commerce with the West Indies and Europe, and owned a number of whaling and fishing vessels. Its commerce was destroyed during the embargo and the war of 1812; and although the whaling business was resumed, it has since been entirely abandoned. Its trade, however, is still important, the principal article of export being pressed hay for the New York market. The chief manufactures are of iron. The Hudson iron company and the Columbia iron works together turn out from 60 to 75 tons of pig iron per day. There are two machine shops, two iron foundries, a stove foundry, manufactories of steam fire engines, paper car wheels, tiles, and pianos, six carriage factories, two breweries, three rectifying establishments, knitting mills, a spoke factory, a pump and block factory, a tannery, a flour mill, three national

banks with a capital of \$750,000, a savings bank, and 10 hotels. The city is lighted with gas, is supplied with drinking water through iron pipes from a spring 2 m. distant, and has an efficient fire department. There are six public schools with about 1,000 pupils, an academy, three public libraries, two daily and three weekly newspapers, an orphan asylum, and 12 churches.—Hudson, originally known as Claverack Landing, was settled in 1783. It was incorporated as a city in 1785. A lunatic asylum was established here in 1832, but given up on the opening of the state asylum at Utica.

HUDSON, a township and village of Summit co., Ohio, at the junction of the Cleveland and Pittsburgh and the Cleveland, Mt. Vernon, and Columbus railroads, 25 m. S. by E. of Cleveland and 120 m. N. E. of Columbus; pop. in 1870, 1,520. The village is pleasantly situated and neatly built. It is the seat of the Western Reserve college, chartered in 1826, which has handsome grounds and five substantial college halls. In 1872-'3 the academical department had 8 professors and instructors, 52 students, and a library of 10,000 volumes; the preparatory department had 2 instructors and 47 pupils. The medical department (Cleveland medical college) is in Cleveland; it was founded in 1843, and in 1871-'2 had 14 professors and instructors, 76 students, and a library of 6,000 volumes. There is also a female seminary.

HUDSON, Henry, a British navigator and discoverer, born about the middle of the 16th century. He was first employed by a company of London merchants to search for the N. W. passage in 1607, when he sailed in a small vessel with a crew of only ten men and a boy to the E. coast of Greenland, lat. 80°, where he was stopped by ice. After three months of fruitless exploration he returned to England, whence he sailed again, April 21, 1608, hoping to find the passage between Nova Zembla and Spitzbergen, but was again hindered by ice, not being able to get to the eastward of the former land. On April 4, 1609, he began another voyage to the N. E. of Asia, sailing from Amsterdam in the service of the Dutch East India company. His crew being unable to endure the climate, he sailed for the American coast, hoping to find a passage N. of Virginia. On July 18 he anchored in a harbor on the coast of Maine. Sailing S., he discovered Delaware bay on Aug. 28 and explored it. Returning, he anchored within Sandy Hook Sept. 3, and on the 11th discovered the river that bears his name. In April, 1610, he began his fourth voyage with 23 sailors, passing in June and July through the strait and into the bay which now bear his name. Finding, however, that this did not give him an open route westward, he resolved to winter there and resume explorations in the spring. His provisions ran short, and he was compelled to return. It is said that he incautiously declared that in their destitute condition he would have to leave some behind, and in a mutiny he

was seized and placed with his son and seven others who remained faithful to him in an open boat, and abandoned. His fate was revealed by one of the mutineers, and an expedition was sent from England in quest of him, but no trace of him was ever discovered. "A Collection of Documents forming a Monograph of the Voyages of Henry Hudson," edited, with an introduction, by George Asher, was published in London by the Hakluyt society in 1860. See also a "Historical Inquiry concerning Henry Hudson," by J. M. Read, jr. (Albany, 1866).

HUDSON, Henry Norman, an American essayist, born in Cornwall, Vt., Jan. 28, 1814. His early youth was passed on a farm; from his 18th to his 21st year he lived in Middlebury as an apprentice at the trade of coachmaking, during which time he prepared himself for college. He graduated at Middlebury college in 1840, and went to Kentucky, where he remained a year engaged in teaching, an occupation which he subsequently followed for two years in Huntsville, Ala. Having during this time applied himself especially to the study of Shakespeare, he wrote and delivered at Huntsville a course of lectures on the great dramatist, which he subsequently delivered in different parts of the country, and finally printed (2 vols. 12mo, New York, 1848). In 1844 he became a communicant of the Episcopal church, and was ordained to the priesthood in New York in 1849. He has since edited the works of Shakespeare (11 vols. 12mo, Boston, 1850-'57), and for a short time edited the "Churchman." He was rector of the Episcopal church in Litchfield, Conn., in 1859 and 1860. In the winter of 1860-'61 he delivered a new course of Shakespearean lectures. During the civil war he was a chaplain in the army, and subsequently taught school in Boston, and for two years edited the "Saturday Evening Gazette." He has published "A Chaplain's Campaign with Gen. Butler" (1865), a "School Shakespeare" (1870), "Shakespeare, his Life, Art, and Characters" (1872), and "Sermons" (1874).

HUDSON, Jeffery. See DWARF.

HUDSON BAY, an inland sea of British North America, between lat. 51° and 64° N., and lon. 77° and 95° W. It is of irregular shape, 850 m. long N. and S., and 600 m. broad. Its S. extremity is called James bay. In its mouth, at the northeast, lies Southampton island; outside of this it communicates with Davis strait by means of Hudson strait, and E. of Southampton island Fox channel extends N. The coasts are generally high, rocky, and rugged. The depth of the middle of the bay has been taken at 150 fathoms, but it is probably more. Southampton island is formed of high rocky masses, and seems to be composed of several small islands separated by straits, always closed however by ice. There are many other islands, and many reefs and sand banks. The principal rivers flowing into the bay are the Great Whale river, on the E. coast; the Main, Abbitibe, Moose, and Albany, into James bay; and

the Weenisk, Severn, Hayes, Nelson, Churchill, and Seal, on the W. coast. It was formerly supposed that there were two tides in the bay, one from the east and another from the west; and this error led to the belief in a channel communicating with the western sea, which was thought to be not far distant. Navigation is possible only during two months, the bay being completely frozen over or obstructed by drift ice during the rest of the year. Before the navigation of the bay was understood, it was usual to take two seasons for a voyage from England; and the captain who succeeded in returning the same year was awarded a prize of £50. Accounts differ as to the abundance of fish in Hudson bay. The Hudson bay company gave little attention to fisheries, yet the white whale is found there, and the whale fishery was once of considerable importance.

HUDSON BAY TERRITORY. See NORTHWEST TERRITORIES.

HUDSON RIVER, in New York, one of the most beautiful and important rivers in the United States. Its remote sources are in the Adirondack mountains, in the N. E. part of the state, more than 4,000 ft. above the sea. Its principal head streams rise in Hamilton and Essex cos., serving as the outlets to a great number of small highland lakes. Several of these streams unite in the S. W. part of Essex co., and the river formed by their junction flows in a tortuous course S. E. to about the centre of Warren co., where it receives the outlet of Schroon lake on the east, about 8 m. W. of the S. part of Lake George. It runs from this point nearly S. to the town of Corinth, on the boundary between Warren and Saratoga cos., receiving on its way the Sacondaga river from the west, and some smaller streams, and then turns sharply to the east, following that general direction with several bends until it reaches Glen's Falls, where it has a fall of 50 ft. Soon after passing this point it sweeps around to the south, and flows in that direction with little deviation to its mouth, a distance of about 190 m., separating Washington, Rensselaer, Columbia, Dutchess, Putnam, Westchester, and New York cos., on the east, from Saratoga, Albany, Greene, Ulster, Orange, and Rockland cos., and the state of New Jersey on the west. From Glen's Falls to Troy its course is much broken by rapids, but at the latter place, 151 m. from its mouth, it is affected by the tide and becomes a broad, deep, sluggish stream. From Albany, 6 m. below Troy, its general width is from 300 to 700 yards, though it greatly exceeds this in certain places. Its banks are elevated and picturesque throughout nearly its whole course. The upper part of the river is bordered by gentle eminences, covered with cultivated fields, interspersed with pleasant towns and villages, while in Greene and Ulster cos. its valley is bounded W. by the Catskill mountains, which in the former approach within 7 m. of the river. A short distance below Newburgh, 61 m. from New York, it begins its passage through

the beautiful hills called the Highlands, which rise abruptly from the water; in some places vessels following the channel pass so near the shore that one can almost touch the cliffs from their decks. The most remarkable of these hills are Breakneck (1,187 ft. in height), Beacon, so named from the signal fires which used to burn on its summit during the revolutionary war (1,685 ft.), Butter (1,500 ft.), Crow Nest (1,428 ft.), Sugarloaf mountain, Bull hill, Anthony's Nose (1,128 ft.), and Dunderberg (Thunder Hill) or Donderbarrack (Thunder Chamber). The Highlands cover an area of about 16 by 25 m., and the river flows through them with many windings, which add greatly to its beauty. In the midst of them, on a bold promontory commanding magnificent views both N. and S., is West Point, the seat of the United States military academy. Fort Putnam, the ruins of which remain, was built here during the war of independence by the Americans, and a chain was stretched across the river at this place to prevent the passage of British ships. Several other sites memorable in the history of that period are pointed out to tourists in various parts of the river. Shortly after emerging from the Highlands the Hudson widens into the expanse known as Haverstraw bay, immediately below which is Tappan bay, extending from Teller's Point to Piermont, about 12 m. long and 3 to 4 m. wide. On the W. shore a range of trap rock called the Palisades rises perpendicularly from the water's edge to a height of from 300 to 500 ft., extending from the New Jersey boundary just below Piermont to Fort Lee, 9 m. from New York bay, the range being thus about 15 m. long. From this place to its mouth the Hudson is between 1 and 2 m. wide. It falls into New York bay in lat. $40^{\circ} 42' N.$, lon. $74^{\circ} 1' 30'' W.$, its whole length being a little over 300 m. Its fall from Albany to its mouth, according to the United States coast survey reports, is only about 5 ft. On the E. side of its mouth lies New York city, on the W. side Jersey City and Hoboken. The Hudson has few tributaries, the largest being the Hoosac, Mohawk, Walkill, and Croton. Spuyten Duyvil creek connects it with the Harlem river, which flows into the East river, forming the N. boundary of Manhattan island. The basin of the Hudson occupies about two thirds of the E. border of the state, and a large part of the interior. The principal cities and towns on its banks are Lansingburgh, Troy, Hudson, Poughkeepsie, Peekskill, Sing Sing, Tarrytown, Yonkers, and New York, on the east, and Waterford, West Troy, Albany, Catskill, Kingston, Rondout, Newburgh, Haverstraw, Nyack, Piermont, Hoboken, and Jersey City on the west. It is navigable by ships to Hudson, by steamboats to Troy, and by sloops, by means of a dam and lock, to Waterford, at the mouth of the Mohawk. The passenger steamers from New York to Albany and Troy are noted for their elegance and fine proportions. A little below

Albany the navigation is at times obstructed by shifting sands called the Overslaugh, for the removal of which large expenditures have been made by the United States government. New York is indebted for much of its prosperity to this river, which forms one of the principal channels of communication between the east and west, and is connected with the great lakes by the Erie canal and the Erie and New York Central railroads, with Lake Champlain and Canada by canal and railroad, and with the Delaware river and the Pennsylvania coal region by the Delaware and Hudson canal. The Hudson River railroad runs along its east bank from New York to Troy, and a railroad has been commenced along its west bank from Jersey City to Albany.—In 1524 Verrazzani, sailing under a commission from Francis I. of France, entered the bay of New York and sailed a short distance up the river in a boat. Henry Hudson discovered it Sept. 11, 1609, explored it above the mouth of the Mohawk, and called it "river of the mountains." This name was soon changed to Mauritius, in honor of Prince Maurice of Nassau; and about 1682 it became generally known as the North river, to distinguish it from the Delaware or South river. The name Hudson's river had been applied to it by the English not long after its discovery in 1609. The Indians are said to have called it Shatemuc and Cahohatatea. The first successful attempt at steam navigation was made on the Hudson by Robert Fulton in 1807.

HUDSON STRAIT, in British North America, connects Hudson bay with the ocean and Davis strait, between lat. 60° and $64^{\circ} N.$, and lon. 65° and $77^{\circ} W.$ Its length is 450 m., its average breadth 100 m., and its least breadth 60 m.

HUÉ, a city of Asia, capital of the empire of Anam, and of the province of the same name, on the Hué roadstead, about 10 m. from the China sea; lat. $16^{\circ} 28' N.$, lon. $107^{\circ} 32' E.$; pop. estimated at from 80,000 to 100,000. It is composed of two cities, an outer and an inner. The former is surrounded by the river, and by walls 5 m. in circumference and 60 ft. high, fortified in the European manner. It is entered by ten bridges and as many corresponding gates, and contains the palaces of the king's near relatives, the different public offices, barracks, prisons, magazines, granaries, and the dwelling houses and shops of the citizens. In the centre of the outer city is the inner one, which is also walled, and in which are the palaces and seraglio of the king, the palace of his mother, the palace wherein the sovereign receives his mandarins, and guard rooms for the sentinels on duty. Hué is a naval station, and has extensive ship yards and a large cannon foundry. The streets are traversed by navigable canals. The roadstead is an excellent and well sheltered harbor. The citadel is fortified after the European fashion, and would require 50,000 men to fully garrison it. The commercial and manufacturing activity of Hué is extensive. In 1787 the city was formally

ceded to the French, but has never been occupied by them.

HUELVA. I. A S. W. province of Spain, forming the W. extremity of Andalusia, bordering on Portugal, the Atlantic, and the provinces of Cadiz, Seville, and Badajoz; area, 4,118 sq. m.; pop. in 1870, 196,469. The larger portion of the province is a picturesque mountain land, being traversed by a continuation of the Sierra Morena, known as the Sierra de Aroche. It is but little cultivated and thinly peopled. It has mines of copper, iron, lead, and coal, salt works, and mineral springs. The copper mines on the Rio Tinto are celebrated. The chief rivers are the Guadiana, which forms part of its western frontier, and the Tinto. The principal towns, besides the capital, are Moguer, Ayamonte, Cartaya, La Palma, Valverde del Camino, and Aracena.

II. A town, capital of the province, situated on a peninsula between the mouths of the Tinto and the Odiel, 50 m. W. S. W. of Seville; pop. about 10,000. It has broad, clean streets, two churches, two hospitals, a high school, a theatre, barracks, a beautiful promenade, and an ancient aqueduct. Copper is largely exported, and there is a brisk coasting trade with Cadiz and Seville. It is the site of the ancient Onoba, of which considerable remains exist.

HUERFANO, a S. county of Colorado, drained by a river of the same name; area, about 2,000 sq. m.; pop. in 1870, 2,250. The surface is generally mountainous. The land along the Huerfano and its branches is fertile, and Indian corn grows well, but stock raising is the chief industry. Some gold and silver is found in the mountains. The Denver and Rio Grande railroad traverses the county. The chief productions in 1870 were 5,597 bushels of wheat, 13,080 of Indian corn, 2,170 of oats, and 37,779 lbs. of wool. There were 281 horses, 1,987 milch cows, 2,349 other cattle, 30,704 sheep, and 413 swine. Capital, Badito.

HUESCA. I. A province of Spain, in Aragon, bordering on France and the provinces of Lérida, Saragossa, and Navarre; area, 5,872 sq. m.; pop. in 1870, 274,623. The N. part, which is covered by offsets of the Pyrenees, is rugged and mountainous; but the S. is level and fertile. The principal rivers are the Cinca, Alcanadre, Isuela, Gallego, and Aragon, all tributaries of the Ebro. Wine, oil, and cattle are produced. Iron, copper, and lead are found, but there is little mining. The manufactures are linen, woollen, and hempen fabrics, &c. The principal towns are Huesca, Barbastro, Fraga, Monzon, and Jaca. **II.** A town (anc. *Osca*), capital of the province, on the Isuela, 35 m. N. E. of Saragossa; pop. about 10,000. It is a place of great antiquity. Sertorius founded here a college for the instruction of Iberian youth in Greek and Roman learning. Julius Cæsar raised it to the dignity of a *municipium*, and honored it with the title of *Osca Urbs Victrix*. In 1096 Pedro I. of Aragon recovered this city from the Moors,

who called it Weshha, and annexed it to his dominions. It is the seat of a bishop, has a beautiful Gothic cathedral, four churches, an episcopal seminary, two colleges, a theatre, and barracks. The university, which was founded by Pedro IV. of Aragon in 1354, has recently been abolished. The industry is confined to tanning and weaving of coarse linen.

HUET, Pierre Daniel, a French scholar, born in Caen, Feb. 8, 1630, died in Paris, Jan. 26, 1721. He studied at Caen and Paris, and travelled in Holland and Sweden in 1652. In 1670 he was appointed by the king sub-preceptor under Bossuet of the dauphin, and he directed for his royal pupil the preparation of the Delphin edition of the classics (*ad usum Delphini*). He was received into the French academy in 1674, became bishop of Avranches in 1689, resigned that office after ten years, and soon afterward entered an establishment of the Jesuits at Paris. His principal works are: *De Interpretatione* (Paris, 1661); *Lettre sur l'origine des romans* (1670), full of curious researches; *Demonstratio Evangelica* (1679); *Censura Philosophiæ Cartesianæ* (1689), in which he appears as an opponent of Cartesianism; *Histoire du commerce et de la navigation des anciens* (Lyons, 1716); and *Traité philosophique de la faiblesse de l'esprit humain* (Amsterdam, 1723), which caused him to be classed among skeptics. He wrote memoirs of his life in Latin (1718); French translation by Charles Nisard, Paris, 1853). His complete works appeared in 1856, in 6 vols.

HUFELAND, Christoph Wilhelm, a German physician, born at Langensalza, Thuringia, Aug. 12, 1762, died in Berlin, Aug. 25, 1836. He studied at Jena and Göttingen, graduated as M. D. in 1783, and was appointed professor of medicine at Jena in 1793. In 1798 he removed to Berlin, and after the establishment of the university of Berlin (1809) he became professor there of special pathology and therapeutics. His work on the art of prolonging life (*Makrobiotik, oder die Kunst das menschliche Leben zu verlängern*, Jena, 1796; 8th ed., Berlin, 1860) was translated into several European languages. Among his other works is one on scrofulous diseases (*Ueber die Natur, Erkenntnismittel und Heilart der Skrophelkrankheit*, Jena, 1795). His work on the physical training of infants (*Guter Rath an Mütter über die wichtigsten Punkte der physischen Erziehung der Kinder in den ersten Jahren*, Berlin, 1799; 10th ed., 1866) produced many reforms in the system of education; while his *Enchiridion Medicum* (Berlin, 1836; 10th ed., 1857), which gives the experiences of his 50 years of practice, is still consulted. His *System der praktischen Heilkunde* (Jena and Leipsic, 1800-'5), and his *Geschichte der Gesundheit* (Berlin, 1812), are much esteemed. He introduced the system of mortuary houses for the prevention of burying alive, the first of which was erected at Weimar under his superintendence; and endowed charitable institutions for poor physicians and phy-

sicians' widows. His autobiography, edited by Göschen, was published in 1863.

HÜGEL, Karl Alexander Anselm, baron, a German traveller, born in Ratisbon, April 25, 1796, died in Brussels, June 2, 1870. He studied law in Heidelberg, served as an Austrian officer in 1813-'14, and held an appointment in the embassy sent to induce Christian, the temporary king of Norway, to resign. In 1821 he went in a diplomatic capacity to Naples, and afterward lived several years in Vienna. In 1831 he set out to visit Greece, Asia Minor, Egypt, Barbary, and remote portions of India and central Asia. He returned to Europe in 1837, bringing with him a collection illustrating ethnography and natural history, as well as antique coins, manuscripts, jewelry, paintings, and silver vessels. The whole collection was purchased for the imperial museum in Vienna. He wrote *Botanisches Archiv* (Vienna, 1837); *Kaschmir und das Reich der Sikhs* (4 vols., Stuttgart, 1840-'42); and *Das Becken von Kabul* (2 vols., Vienna, 1851-'2).

HUGER. I. Isaac, an American revolutionary general, born at Limerick plantation, S. C., March 19, 1742, died in Charleston in November, 1797. He was one of five patriot brothers active in the revolution. Their parents were wealthy, and the sons completed their education in Europe. Isaac first served under Col. Middleton in the expedition against the Cherokees in 1760. He was made lieutenant colonel of the 1st South Carolina regiment, June 17, 1775, and subsequently colonel of the 5th regiment; took a conspicuous part in the engagements connected with the siege of Savannah in 1778; was made a brigadier general Jan. 19, 1779; commanded a force of cavalry at the siege of Charleston in 1780, which was surprised and dispersed by Tarleton; and commanded the Virginia brigade which formed the right wing in the battles of Guilford Court House, March 15, 1781, and Hobkirk's Hill, April 25, 1781. **II. Francis Kinlock**, an American officer, nephew of the preceding, born in 1764, died in Charleston, S. C., Feb. 15, 1855. His father, Major Benjamin Huger, was killed before the lines of Charleston in 1779. After being a pupil of Dr. John Hunter, and a fellow student of Dr. Physick in Philadelphia, he joined with Dr. Eric Bollmann in a daring but unsuccessful attempt to rescue Lafayette from Olmütz. (See BOLLMANN.) Huger was arrested and for eight months kept in severe confinement. He returned home, and in 1798 became a captain in the army, was a colonel in the war of 1812, and served in both branches of the legislature of his state. **III. Benjamin**, son of the preceding, born in Charleston in 1806. He graduated at West Point in 1825, and was commander at Fortress Monroe from 1841 to 1846. He served as chief of ordnance to Gen. Scott in the Mexican war, was successively brevetted as major, lieutenant colonel, and colonel, and from 1854 to 1860 was in command of the arsenal at Pikesville, Md. He resigned

his commission in April, 1861, entered the confederate service, and was soon made major general. His conduct during the campaign on the peninsula was severely censured, and he was removed from active service soon after.

HUGGINS, William, an English astronomer, born in London, Feb. 7, 1824. He was educated at the city of London school and by private tutors, and devoted himself successively to natural philosophy, astronomy, and microscopy, attaining great proficiency in each. In 1855 he erected an observatory near his residence at Upper Tulse hill, furnishing it with a transit instrument and an equatorial of 8 in. aperture manufactured in Cambridge, Mass. At first he was occupied with observations of double stars, and he also made drawings of Mars, Jupiter, and Saturn; but later he gave almost his entire attention to the application of spectrum analysis to the examination of comets and nebulae, and his most valuable achievements have been in this field. In 1862, as a preliminary task, he spent several months in mapping the spectra of 26 chemical elements; the results are published in the "Philosophical Transactions" for 1864. In his prismatic observation of the stars he was assisted by Dr. William A. Miller, and the gold medal of the royal astronomical society was awarded to them jointly in 1867, Mr. Huggins having received one of the royal medals in 1866. He has proved that the proper motion of a star in the line of sight can be determined by any small change of position in the lines of the spectrum, and thus he calculates that Sirius is moving away from the earth at the rate of 27 m. a second. He has made valuable observations on the solar prominences, showing how their forms may be seen, and has detected the heat received at the earth from some of the fixed stars. In 1869 he delivered the Rede lecture at Cambridge, in which he gave an account of his discoveries. In 1871 the royal society placed at his disposal a telescope of 15 in. aperture, which was placed in a new observatory at Upper Tulse hill. For an account of his observations of the spectra of comets, see COMET, vol. v., p. 141.

HUGH CAPET, king of France and the founder of the Capetian dynasty, born about 940, died Oct. 24, 996. When still a child he inherited from his father, Hugh the Great, the duchy of France and the county of Paris, thus taking rank among the most powerful princes of his country. On the death of Louis V., the last of the Carolingian kings, a number of nobles and bishops from all parts of the country assembled at Senlis to settle the succession, and selected Hugh Capet in preference to the Carolingian duke Charles of Lorraine, the uncle of the late king. Hugh was consequently crowned at Noyon, July 3, 987, by the archbishop of Rheims. Notwithstanding this election, Charles supported his claims to the crown of France by the sword, and after four years' hostilities was apparently on the point of suc-

ceeding, when he was treacherously made prisoner by Adalbéron, bishop of Laon, who delivered him to his rival. The unfortunate prince was sent to Orleans, where he soon breathed his last in a dungeon. Hugh, having thus secured possession of the crown, associated his son Robert in the government, which he settled on the principle of hereditary succession. (See CAPETIANS.)

HUGHES, Ball, an American sculptor, born in London, England, Jan. 19, 1804, died in Boston, Mass., March 5, 1868. When only 12 years old he made out of wax candle-ends a bass-relief copy of a picture representing the wisdom of Solomon, which was afterward cast in silver. He spent seven years in the studio of Edward Hodges Bailey, and competed successfully for the prizes awarded by the royal academy and the society of arts and sciences. Among his works at this period, besides several ideal statues, were busts of George IV. and the dukes of Sussex, York, and Cambridge. In 1829 he emigrated to New York, where he executed a marble statue of Hamilton, which was destroyed in the merchants' exchange, in the great fire of 1835. He also made a monumental alto-relief, of life size, in memory of Bishop Hobart, which is now in Trinity church. Several of his casts are in the Boston athænaeum, and his bronze statue of Nathaniel Bowditch is in Mt. Auburn cemetery, Cambridge, Mass. He also appeared as a lecturer on art.

HUGHES, John, an American archbishop, born near Clogher, county Tyrone, Ireland, in 1797, died in New York, Jan. 3, 1864. He was, to use his own words in his well known letter to Mayor Harper, "the son of a farmer of moderate but comfortable means." Being the youngest of three sons, he was allowed to indulge an early passion for books, and was sent for a time to a Latin school. In 1816 his father came to the United States. John followed him in 1817, and in 1818 the whole family settled near Chambersburg, Pa. Toward the end of that year John obtained admission to the college of Mount St. Mary's, at Emmettsburg, Md. "I was to superintend the garden," he afterward wrote, "as a compensation for my expenses, until I might be appointed teacher, prosecuting meanwhile my studies under a private tutor." Toward the close of 1825 he was ordained priest, and placed in charge of a small mission at Bedford, Pa. A few weeks afterward he was appointed pastor of St. Joseph's church, Philadelphia, where he soon gained reputation as a pulpit orator. On May 31, 1829, he preached a sermon on Catholic emancipation, which was published in pamphlet form and dedicated to O'Connell. In 1830 he accepted a challenge from the Rev. John Breckenridge, D. D., a distinguished Presbyterian clergyman, to discuss through the press the question, "Is the Protestant religion the religion of Christ?" In 1831-'2 he built St. John's church, Philadelphia, of which he was the rector as long as he remained in that city. In 1834

he accepted a second challenge from Dr. Breckenridge to a public oral discussion of the question, "Is the Roman Catholic religion hostile to liberty?" The debate created much interest, was brought to an unsatisfactory termination, and afterward appeared in book form. Mr. Hughes was appointed coadjutor bishop of New York in 1837, received episcopal consecration Jan. 7, 1838, and in 1839 became administrator of the diocese, which then comprised the entire state of New York and part of New Jersey, with a Catholic population of 200,000, and only 40 clergymen. He forthwith set to work to remedy the evils springing from the "trustee system" of holding church property. The titles were vested in laymen, who frequently came into conflict with the episcopal authority, and were sometimes supported in their opposition by priests suspended from their office. Several churches had in consequence been closed to divine worship; most of them had become deeply involved in debt, and of the eight churches in New York city, five were on the point of being sold. Bishop Hughes set about consolidating these debts, removing the lay trustees, and securing the titles in his own name. In spite of every obstacle he succeeded, and thus put an end to scandalous contentions. He next purchased a large property at Fordham, Westchester co., with the intention of opening there a college and theological seminary. For the purpose of obtaining money and the aid of religious communities for the institutions which he planned, he went to Europe in 1839. During his absence the Catholics of New York set up an organized opposition to the public school system. To prevent this movement from becoming a purely political one, Bishop Hughes on his return took himself the lead, and drew up a petition to the common council praying, in the name of the Catholic citizens, that seven parochial schools should be designated as "entitled to participate in the common-school fund, upon complying with the requirements of the law." Remonstrances to this petition were sent in by the public school society and the pastors of the Methodist Episcopal church, and on Oct. 29 both parties appeared before the common council. Bishop Hughes met and answered, for several days in succession, the array of eminent counsel opposed to him, and supported his petition in an elaborate speech; but his demands were rejected by the common council. The matter was then brought before the legislature; but being baffled in his suit there, he recommended Catholics to nominate independent candidates in the ensuing elections; a movement which developed such unexpected strength that a modification of the school system was soon afterward effected. In 1841 he was able to open regular courses of classical and theological instruction in St. John's college, Fordham. In 1842, after the death of Bishop Dubois, Dr. Hughes succeeded him as titular bishop of New York. In August of

that year was held the first diocesan synod of New York, whose decrees on secret societies and the tenure of church property were published officially by the bishop in September; and this legislation was further supplemented by the publication in 1845 of "Rules for the Administration of Churches without Trustees." On March 10, 1844, he consecrated as his coadjutor the Rev. John McCloskey, D. D. During the spring and summer of this year fears were entertained of anti-Catholic riots in New York, such as had taken place in Philadelphia. Bishop Hughes thereupon addressed a letter to Mayor Harper, which calmed the public excitement, and in a series of letters denounced the editor of the "New York Herald" for attacks on himself. A second visit to Europe in December, 1845, enabled him to secure the services of the Jesuits, Christian brothers, and sisters of mercy. On his return he was solicited by President Polk to accept a peace mission to Mexico, which he declined. In 1847 he delivered in the hall of representatives at Washington, by request of both houses of congress, a discourse on "Christianity, the only Source of Moral, Social, and Political Regeneration." During this year his diocese was divided by the creation of the sees of Albany and Buffalo. In 1850 the see of New York was raised to metropolitan rank, and Bishop Hughes received the pallium as archbishop in Rome at the hands of the pope. In 1853 the sees of Brooklyn, Burlington, and Newark were erected, and the new bishops were consecrated by the nuncio, Archbishop (afterward Cardinal) Bedini, Oct. 30. Archbishop Hughes presided in 1854 over the first provincial council of New York; was in Rome at the proclamation of the dogma of the immaculate conception, Dec. 8; and on his return was involved in a controversy with Mr. Erastus Brooks, the letters on both sides being published in a volume entitled "Brooksiana." In August, 1858, he laid the corner stone of a new cathedral on Fifth avenue, New York, the largest yet planned in the United States. In the preceding autumn, while accompanying the nuncio to Canada, he was seized with lung fever, from the effects of which he never wholly recovered. He persisted nevertheless in the discharge of his daily duties, causing himself toward the end of his life to be carried to the altar when conferring confirmation. At the breaking out of the civil war, and before active operations had begun in Virginia, Archbishop Hughes, though in very feeble health, went to Washington to proffer the aid of his priests, sisters of charity, and sisters of mercy. In November, 1861, at the solicitation of President Lincoln, he went to Europe in company with Mr. Thurlow Weed, in order to secure the friendly neutrality of some governments, particularly of the French court. After visiting France and Italy, he preached at the laying of the corner stone of the Catholic university of Dublin, June, 1862. He ap-

peared at the New York academy of music in April, 1863, to make an appeal in favor of the famishing Irish, and in July made his last public address to quell the draft riots. Thenceforward his strength steadily declined until his death. His works have been published by L. Kehoe (2 vols., New York, 1864-'5); and his life has been written by John R. G. Hassard (8vo, New York, 1866).

HUGHES, Thomas, an English author, born near Newbury, Berkshire, Oct. 20, 1823. He was educated at Rugby, and graduated at Oriel college, Oxford, in 1845. He studied law, was called to the bar in 1848, and became queen's counsel in 1869. From 1865 to 1868 he was a liberal member of parliament for the borough of Lambeth, and from 1868 to January, 1874, for the borough of Frome, which was not contested by the liberals in the election of February, 1874, and consequently a conservative took his place. While in parliament he supported the bills for the disestablishment of the Irish church, and for secularizing the universities, abolishing tests, and admitting dissenters to fellowship in Oxford and Cambridge. He took an active interest in educational and social questions and in all measures for the improvement of the laboring classes. In 1869 and 1870 he visited the United States, lecturing in the principal cities, and was well received. He is the author of "Tom Brown's School Days," a graphic description of life at Rugby school under Dr. Arnold (1856); a sequel to it entitled "Tom Brown at Oxford" (1861); "The Scouring of the White Horse" (1858); "Religio Laici," a semi-theological essay (1862); "Alfred the Great" (1869); and "Memoirs of a Brother" (1873). He has also written critical prefaces to English editions of a work on "Trades Unions" by the count de Paris, Lowell's "Biglow Papers," and the poems of Walt Whitman.

HUGHES, a S. county of Dakota, bounded S. W. by the Missouri, recently formed and not included in the census of 1870; area, about 800 sq. m. It is intersected by East Medicine Knoll river, and watered by several small affluents of the Missouri.

HUGO, Gustav, a German jurist, born at Lör-rach, Baden, Nov. 23, 1764, died in Göttingen Sept. 16, 1844. He studied at Göttingen from 1782 to 1785, and first became known by his edition of the "Fragments of Ulpian" (Göttingen, 1788). In 1788 he was appointed professor extraordinary and in 1792 regular professor of law at the university of Göttingen. He was one of the first to follow the example of Leibnitz and of Pütter, presenting the Roman law classified with reference to the principal eras of its history. His principal works are: *Lehrbuch der Geschichte des römischen Rechts* (Berlin, 1790; 9th ed., 1824); *Lehrbuch eines civilistischen Cursus* (7 vols., 1799-1812); and *Beiträge zur civilistischen Bücherkenntniss der letzten vierzig Jahre* (2 vols., 1829). He edited the *Civilistische Magazin* from 1814 to 1837.

HUGO, Victor Marie, a French poet and novelist, born in Besançon, Feb. 26, 1802. The son of an officer whose military duties called him out of France, he was carried in childhood to Elba, Corsica, Switzerland, and Italy. In 1809 he was taken to Paris; and here for two years, under the exclusive supervision of his mother and the care of an old priest, he commenced his classical studies in company with an elder brother, Eugène, and a young girl who afterward became his wife. In 1811, his father having been made general and appointed major-domo of Joseph Bonaparte, the new king of Spain, Victor went to Madrid, and entered the seminary of nobles with a view of becoming one of the pages of Joseph; but subsequent events defeated this design. In 1812 Mme. Hugo returned to Paris with her two sons, and had their classical education continued by the same clergyman who had already instructed them. On the fall of the empire a separation took place between the general and his wife; and thenceforth the young man was placed entirely under the control of the former. He entered a private academy to prepare himself for admission to the polytechnic school. Here he evinced some taste and ability for mathematics, but a much stronger inclination toward poetry; and his first poems gave promise of such talent that his father was finally persuaded to allow him to follow literature as his vocation. In 1817 he presented to the French academy a poem upon *Les avantages de l'étude*. He afterward won three prizes in succession at the Toulouse academy of floral games. His first volume of *Odes et ballades* (1822) created a sensation. Two novels, *Han d'Islande* (1823) and *Bug-Jargal* (1825), exhibited him as an original and forcible prose writer, but already displayed that predilection for the horrible and monstrous which characterizes most of his greater productions. His second volume of *Odes et ballades* appeared in 1826. About this period, in conjunction with Sainte-Beuve, Antoine and Émile Deschamps, A. de Vigny, Boullanger the painter, and David the sculptor, he formed a kind of literary association, called the *Cénacle*, in the meetings of which new literary and artistic doctrines were debated. They also established a periodical, called *La muse française*, which attracted little attention. The drama of *Cromwell* (1827), although unsuitable for the stage, was presented as a specimen of the literary reforms aimed at by the new school; but it had much less importance than the preface, which was a treatise on æsthetics. Thenceforth Victor Hugo was the acknowledged leader of the romanticists, who waged earnest war against their opponents, the classicists. His claims to this distinction were strengthened in 1828 by the publication of *Les orientales*. *Le dernier jour d'un condamné*, which followed, fascinated the public by its vivid delineation of the mental tortures of a man doomed to execution. The contest

between the two opposite schools reached its climax when, on Feb. 26, 1830, the drama of *Hernani* was produced at the Théâtre Français. In 1831 Hugo won another dramatic triumph with *Marion Delorme*, while his lyrical poems *Les feuilles d'automne* and his novel *Notre Dame de Paris* were received with enthusiasm. The performance of his dramas, *Le roi s'amuse* (1832), *Lucrèce Borgia* and *Marie Tudor* (1833), *Angelo, tyran de Padoue* (1835), *Ruy Blas* (1838), and especially *Les burgraves* (1843), drew forth marked approbation; his political poems, *Les chants du crépuscule* (1835), *Les voix intérieures* (1837), and *Les rayons et les ombres* (1840), were highly popular; and his miscellaneous writings, *Claude Gueux*, *Étude sur Mirabeau*, *Littérature et philosophie mêlées* (1834), and *Le Rhin* (1842), were scarcely less successful. His literary reputation had secured his election to the French academy in 1841, notwithstanding the opposition of the members attached to the old classic school; and having thus reached the highest distinction in literature, he now indulged in political aspirations, which were partly gratified by his being created in 1845 a peer of France by King Louis Philippe. On the revolution of February, 1848, he was elected a deputy to the constituent assembly, where he generally voted with the conservative party. On his reelection to the legislative assembly, he evinced more democratic and socialistic tendencies. In vehement speeches he denounced the reactionary tendencies of the majority, and the secret policy of President Louis Napoleon. On the *coup d'état* of Dec. 2, 1851, Hugo was among those deputies who vainly attempted to assert the rights of the assembly and to preserve the constitution. His conduct led to his proscription; he took refuge in the island of Jersey, where, while resuming his literary pursuits, he continued his opposition to Louis Napoleon, publishing *Napoléon le Petit* (1852), and his bitter satires *Les châtimens* (1853). Two years later he was compelled, on account of some hostile manifestation to the French government, to remove to the island of Guernsey. He refused to accept the amnesty offered to political exiles in 1859. In 1856 he published *Les contemplations*, a collection of lyrical and personal poems, and in 1859 *La légende des siècles* (2 vols. 8vo), a series of poems mainly of an epical character. *Les misérables*, a romance which had been announced several years before, appeared in nine languages simultaneously at Paris, London, Brussels, Madrid, Berlin, St. Petersburg, Turin, and New York (April, 1862). Its success equalled that of any of his previous works. An illustrated edition, published in parts (Paris, 1863-'5), attained a sale of 150,000 copies. In 1865 he published *Chansons des rues et des bois*, in which all the peculiarities of the author were exhibited in an exaggerated degree. *Les travailleurs de la mer* (1866) was also very popular; but *L'homme qui rit* (1869),

in which the author's fondness for monstrous caricature was carried to its height, did not attain so great a success. In 1869 he again refused to avail himself of the privilege of returning to France afforded him by the emperor's proclamation of amnesty of Aug. 15. He published in the *Rappel* a protest against the *plébiscite* of May 8, 1870, ratifying the new reforms of the empire, the violence of which caused it to be officially condemned. After the fall of the emperor and the proclamation of the republic he returned to Paris, and soon after issued an address to the Germans calling upon them to proclaim a German republic and extend the hand of friendship to France. On Feb. 8, 1871, he was elected one of the 43 representatives of the department of the Seine in the national assembly. He there vehemently opposed the parliamentary treaty of peace between France and Germany. This aroused against him the anger of the party of "the right," and on March 8, when he attempted to address the assembly, the opposition was so violent that he left the tribune and immediately resigned his seat. Returning to Paris when the insurrection of the commune broke out, he vainly protested in the *Rappel* against the destruction of the Vendôme column, and soon after went to Brussels, where on May 26 he wrote a letter protesting against the course of the Belgian government in regard to the insurgents of Paris, and offering an asylum to the soldiers of the commune. This excited the hostility of the Belgian government and of the populace of Brussels; his house was surrounded in the night by a mob, and he escaped only by the intervention of the police. Being required by the government to quit Brussels, he went to London, and after the condemnation of the leaders of the commune he returned to Paris and interceded with M. Thiers energetically, though vainly, in behalf of Rossel, Rochefort, and others of the communist leaders. At the election in Paris on Jan. 7, 1872, he was presented by all the radical newspapers as their candidate, but was defeated. During the siege of Paris a new edition of *Les châtimens* was published, and more than 100,000 copies were sold. In 1872 he published a volume of poetry entitled *L'Année terrible*, depicting the misfortunes of France. On May 10 of that year he commenced, in company with his son François and others, the publication of a democratic journal called *Le Peuple Souverain*. His latest novel, *Quatre-vingt-treize* (1874), relates to the war in the Vendée, and introduces Robespierre, Danton, and Marat. It was published simultaneously in French, English, Russian, Italian, Spanish, Portuguese, Dutch, Hungarian, and other languages, Hugo deriving 80,000 francs from these translations alone. The latest edition of Hugo's works, complete to the time of publication, was published in Paris in 1862-'3, in 20 vols. 12mo.—Two of his sons, CHARLES VICTOR (born in 1826, died March 16, 1871),

and FRANÇOIS VICTOR (born in 1828, died Dec. 26, 1873), distinguished themselves as pupils of the Charlemagne college, and in 1848-'50 contributed to the newspaper *L'Événement*, which supported the politics of their father. The elder, on account of an article on the death penalty, was sentenced to six months' imprisonment. Both accompanied their father in his exile, and devoted their leisure hours to literature. Charles published several light novels, among which *La Bohème dorée* was especially successful. François, after translating with considerable success the sonnets of Shakespeare into French, began in 1859 a translation of his dramatic works, which he completed in 1865. The brothers returned to France in 1869, and commenced the publication of the *Rappel* in company with Rochefort, who however soon separated from them. François at the time of his death had nearly completed an edition of a posthumous work by his brother Charles, *Les hommes de l'exil*.—One of the two brothers of Victor Hugo, JULES ABEL (born in 1798, died in 1855), deserves mention as a literary man. Among his many publications were: *Histoire de la campagne d'Espagne en 1823* (2 vols. 8vo, Paris, 1824); *France pittoresque, ou Description des départements et colonies de la France, &c.* (3 vols. 4to, 1833); *France militaire, histoire des armées françaises de terre et de mer de 1792 à 1833* (5 vols. 4to, 1834); and *France historique et monumentale, histoire générale de France depuis les temps les plus reculés jusqu'à nos jours* (5 vols. 4to, with maps and plans, 1836-'43).

HUGUENOTS, a name of uncertain origin, first applied by the Roman Catholics of France to all partisans of the reformation, but subsequently restricted to the Calvinists. Some derive it from one of the gates of the city of Tours called Hugons, at which these Protestants held some of their first assemblies; others from the words *Huc nos*, with which their protest commenced; others from *aignos* (Ger. *Eidgenoss*), a confederate. The *Dictionnaire de Trévoux* suggests its derivation from the hiding in secret places and appearing at night like King Hugon, the great hobgoblin of France. Prof. Mahn, in his *Etymologische Untersuchungen*, who quotes no fewer than 15 different derivations, derives the word himself from Hugues, the name of some conspirator or heretic, from which it was formed by the addition of the French diminutive ending *ot*. The reformation in France was but little influenced by Luther, and before Calvin took the lead was almost entirely self-developing. "It was not," says D'Aubigné, "a foreign importation. It was born on French soil; it germinated in Paris; it put forth its shoots in the university itself, that second authority in Romish Christendom." Anti-Catholic influences had been at work in France from an early age. Arianism had for several centuries been the prevailing religion of a part of southern France, and though it was finally rooted out by the victory of the

Catholic Franks, there remained a widespread dissatisfaction with the religion of the victors. Throughout the middle ages the national sentiment of the race of Languedoc, as the history of the Albigenses and kindred sects amply proves, was prone to sympathize and to identify itself with demands for religious reform, and even with open secession from the church of Rome. (See CATHARISTS.) To these influences was added during the reign of Francis I. the very important aid of courtly fashion, or rather the sympathy of those nobles and scholars who had become interested in the revival of letters, and who in France, as in Germany and other countries of Europe, were involved in animated conflicts with the monks and the prominent theologians of the churches. These elements of courtly, scholarly, or popular opposition to the church gave birth not merely to the humor of Rabelais, but to the poetry and philosophy which sprung up around the beautiful Marguerite of Valois, queen of Navarre, from whom the spirit of the reformation was transmitted to Jeanne d'Albret, the mother of Henry IV. At this court all poets, scholars, and clergymen more or less tinctured with the spirit of reform, such as Lefèvre, Farel, and Roussel, were welcome; and for a time it seemed as though the court and the government of France might be gained for the cause of the reformation. But at length Francis I., like his opponent the emperor Charles V., decided in favor of the old church, as the papal nuncio succeeded in convincing him that "a new religion disseminated among the people must result in a change of kings." In the city of Meaux, around its bishop Bricconnet, a large body of men inclined to the new faith began, without formally professing schism, to act as reformers. Among these were Gérard Roussel, François Vatable, Martial Mazurier, Jossé Clichou, Michel d'Arande, and Guillaume Farel. Their labors, joined to the political and social agitations of the day, soon attracted persecution. It is remarkable that this persecution in France acted so effectually on the French reformation as to free it in a great measure from excesses such as those of the Anabaptists in Germany. Yet it would probably have fallen away had not the strong hand of Calvin taken it up (1528). Hence we find the French reformers embodying Calvin's ideas of church government and discipline in a common confession of faith, which was formally done at the celebrated general synod in May, 1559. During the reign of Henry II. (1547-'59) the Huguenots gathered such strength as to entertain hopes of becoming the dominant political party; hopes which were confirmed by the fact that several of the royal family, such as the king of Navarre, his brother the prince de Condé, and many of the nobility, including the Châtillons and Admiral Coligni, favored the reformation. From this blending of religious reform with politics arose the conspiracy of Amboise, whose object was to overthrow

the power of Duke François of Guise and his brother the cardinal de Lorraine, who with Mary of Scotland ruled the kingdom through the feeble-minded boy-king Francis II. The king of Navarre and prince de Condé were deeply involved in this plot, and would have suffered death with their Calvinist friends had it not been for the unexpected demise of the king. This occasioned a pause in persecution, of which the queen mother, Catharine de' Medici, and the ruling party availed themselves for political purposes, becoming more moderate in their treatment of reformers. By extending toleration to the Augsburg confession, the cardinal de Lorraine shrewdly fomented quarrels between the Calvinists and Lutherans. This state of affairs, which led to terrible commotions, was again temporarily checked by the edict of January, 1562. At this time, during the reigns of two successive kings whose intellectual inferiority rendered a regency always necessary (after 1559), Catharine de' Medici held the reins of authority, while the dukes of Guise supported by the Catholics, and the princes of Bourbon by the Huguenots, contended for the regency. Some liberal concessions, made for the sake of policy by Catharine and the Guises to the Huguenots, excited the anger of the Catholics, and to allay these feelings war was renewed and raged till the peace of St. Germain (1570), when full liberty was guaranteed the Huguenots, and the king's sister given as wife to Henry of Navarre. The leading Protestants were invited to Paris to the nuptials, where on the day of St. Bartholomew, 1572, a general massacre of Protestants was attempted at the instigation of the queen mother. The Huguenots, with Henry of Navarre as leader, now battled against the holy league formed by the Guises and Philip II. of Spain. Charles IX. died a victim to nervous excitement (1574), and Henry III., disgusted with the tyranny of the league, had Henry, duke of Guise, and the cardinal put to death, and fled for safety to the Protestant camp. He was himself assassinated by the Dominican Clément (1589), and was succeeded by Henry of Navarre, who, to pacify these terrible disorders in France, became a Catholic, but secured full freedom of conscience and all political and religious rights to the Huguenots by the edict of Nantes (1598). The murder of Henry IV. by Ravaillac (1610) left the Protestants without a protector. Under his young son and successor Louis XIII. their rights were soon attacked. Cardinal Richelieu, determined to build up royal power and crush all jarring elements, at one time made war upon the Protestants, driving them into an unlucky league with England, which resulted in the siege and capitulation of La Rochelle. But his treatment of them was on the whole tolerant, though its ultimate result was to greatly diminish their numbers and weaken their power. From 1629 to 1661, under Richelieu and especially under his successor Mazarin, there was comparative rest. After the death of Mazarin

several edicts were again published in rapid succession which aimed at reducing and finally exterminating the Huguenots. Colbert, from considerations of national economy, made the utmost efforts to secure toleration for them, but they were of little avail. Two years after his death, in 1685, Louis XIV. published the celebrated revocation of the edict of Nantes, on which occasion at least 500,000 Protestants took refuge in foreign countries. From this time, for many years, their cause was completely broken in France. In the wild mountains of the Cévennes, the religious peasants, under the name of Camisards, waged war against the royal troops for the defence of Protestant principles; but they had finally to succumb. In 1705 there was not a single organized congregation of Huguenots left in all France. Soon, however, the scattered remnants were again collected and the church reorganized by the indefatigable Jean Court. Although under the reign of Louis XV. severe ordinances were again issued against them, they continued to increase, and in the middle of the century found a powerful aid in men like Montesquieu and Voltaire. Their position was greatly improved on the accession of Louis XVI. (1774), and finally the revolution restored to them their full rights, which have been substantially respected by all the succeeding governments of France. The right of convening general synods of the church was, however, not recovered till 1872. The term Huguenot had long before ceased to be the common name of the church, which is now known as the Reformed church of France.—So early as 1555, Coligni attempted, but without success, to establish a Huguenot colony in Brazil. In 1562 he sent out two ships, under the command of Jean Ribault, on a voyage of exploration to Florida, but the attempt to establish a colony was unsuccessful. Many departed for North America even before the revocation of the edict of Nantes. Some settled in and around New Amsterdam, now New York, where their family names are frequent. Others found homes in Massachusetts, Rhode Island, and Virginia. But South Carolina was their favorite resting place, and a large number of the foremost families in that state are of Huguenot origin. This class of emigrants has contributed, in proportion to its numbers, a vast share to the culture and prosperity of the United States. Wherever they settled they were noted for severe morality, great charity, and politeness and elegance of manners. Of seven presidents who directed the deliberations of the congress of Philadelphia during the revolution, three, Henry Laurens, John Jay, and Elias Boudinot, were of Huguenot parentage.—Among the copious existing sources of Huguenot history, the principal are: Beza, *Histoire ecclésiastique des Églises réformées du royaume de France* (Antwerp, 1580); Weiss, *Histoire des réfugiés protestants de France* (Paris, 1843; translated by H. W. Herbert, New York, 1854); Gieseler,

Lehrbuch der Kirchengeschichte (Bonn, 1845-'7); Berthold, *Deutschland und die Hugenotten* (Bremen, 1848); Félice, *Histoire des protestants de France* (Paris, 1851); the *Bulletin de la société de l'histoire du protestantisme français*; *La France protestante*, by Eugène and Émile Haag (9 vols., Paris, 1859); Smiles, "The Huguenots: their Settlements, Churches, and Industries in England and Ireland" (London, 1867; American edition, New York, 1869, containing a valuable appendix on the Huguenots in the United States, by G. P. Disosway, a descendant of a Huguenot family); Hugues, *Histoire de la restauration du protestantisme de France au XVIII^e siècle* (2 vols., Paris, 1872).

HULIN, or **Hullin**, **Pierre Augustin**, count, a French general, born in Paris, Sept. 6, 1758, died Jan. 9, 1841. He enlisted in the army when scarcely 13 years old, entered the regiment of French guards, and was a sergeant when the revolution broke out. He sided with the people, distinguished himself by his valor and humanity at the taking of the Bastille, July 14, 1789, and was appointed captain in the national guards under Lafayette. During the reign of terror he was imprisoned, but was liberated after the fall of Robespierre. In 1796 he joined the army of Italy under Bonaparte, who appointed him adjutant general; he was governor of Milan in 1797-'8, and was in Paris on the 18th Brumaire, when he supported his general. He followed Bonaparte in Italy during the campaign of Marengo; was made brigadier general in 1803; presided over the court martial which sentenced the duke d'Enghien to death, March 21, 1804; received the rank of general of division and the command of the first military division in 1807; and was the next year created count of the empire. He held the command of Paris until the first restoration; and although, after the abdication of Napoleon, he had sent in his adhesion to the new government, he was dismissed by the Bourbons. He resumed his post during the hundred days, was arrested on the second restoration, and compelled to leave France, but was allowed to return in 1819. Under the title of *Explications offertes aux hommes impartiaux au sujet de la commission militaire institutée en l'an XII pour juger le duc d'Enghien* (Paris, 1823), he published a plain account of his part in that tragedy.

HULL, or **Kingston-upon-Hull**, a municipal and parliamentary borough and seaport of England, in the East riding of Yorkshire, on the river Hull, at its mouth in the Humber, 34 m. S. E. of York, 154 m. N. of London, and 20 m. from the sea; pop. in 1871, 121,598. It is built on a low plain, protected against inundation by artificial means, and extends more than 2 m. along the W. bank of the Hull, and nearly the same distance along the N. bank of the Humber. The streets are very irregular, but are mostly well paved, lighted, and drained. The residences of the wealthy inhabitants are principally in the parish of Sculcoates and the

quarter called Myton. A part of the town built along the left bank of the Hull is connected with the remainder by a bridge of four arches. On the point of land formed by the junction of the two rivers there is a fort which commands the whole harbor. Adjoining it is the Victoria dock. The old dock, opened in 1778 on the Hull, is nine acres in extent, and can accommodate 100 square-rigged ships. There is also a railway dock at the terminus of the Hull and Selby railway. Other docks have been built of late years, and the total area of all the docks of Hull in 1874 was about 87½ acres. The principal public buildings are the custom house, exchange, post

Town Hall, Hull.

office, mansion house, courts of law, jail and house of correction, assembly rooms and museum, concert rooms, two theatres, several banks, and corn exchange. The Holy Trinity church is a handsome cruciform edifice of several dates; the oldest portion was built in 1270. The town has several charitable schools, one of which educates 36 boys to be seamen, and is connected with the Trinity house founded in 1366 for the relief of decayed seamen and the widows of seamen. There is a marine hospital attached to it. Hull college, founded in 1838, occupies a fine Grecian building. There are also a lunatic asylum, a general infirmary, a school of medicine and anatomy, various literary associations with libraries, and botanic

and zoölogical gardens and a "People's Park" of 27 acres given by Sir Z. C. Pearson in 1864. The manufactures include canvas, chains, machinery, earthenware, chemicals, leather, sugar, cotton and linen goods, &c. There are ship-building yards, rope walks, saw mills, grist mills, bone mills, and oil mills. The principal exports are hardware and manufactures of cotton and woollen; the imports, timber, tar, pitch, rosin, grain, wool, flax, hemp, iron, hides, tallow, horns, bones, &c. The trade is chiefly along the coast, with the Baltic ports, and with Germany, Holland, Belgium, Denmark, and America. Hull is an important station for steam packets which connect it with various ports of Great Britain and the continent, and also has railway communication with nearly all parts of the kingdom. The total imports in 1871 were valued at £15,076,095, the exports at £27,387,071. The entrances were 3,417 vessels, of 1,188,841 tons; clearances, 2,911 vessels, of 1,044,158 tons. Hull ranks as the third port in the kingdom.

HULL, Isaac, an American naval officer, born at Derby, Conn., March 9, 1775, died in Philadelphia, Feb. 3, 1843. He commenced his career in the merchant service, and was commissioned as lieutenant in the navy at the commencement of hostilities with France in 1798. In 1800 he was first lieutenant of the frigate *Constitution*, and performed a very gallant achievement in cutting out a French letter of marque from under the guns of a strong battery in the harbor of Port Platte, Santo Domingo. During the war with Tripoli, 1802-'5, Hull served with distinction in the several attacks on the city of Tripoli in July, August, and September, 1804, and subsequently coöperated with Gen. Eaton in the capture of Derne. In 1806 he was made captain. At the opening of the war of 1812 between the United States and Great Britain, he was in command of the frigate *Constitution*, and in July of that year, while cruising off New York, he fell in with a British squadron consisting of a razeed of 64 guns and four frigates, which chased the *Constitution* closely for nearly three days and nights. By the greatest efforts, and the exercise of a skill in handling his ship which excited the admiration of his pursuers, he succeeded in escaping. After this remarkable feat, Hull went into Boston for a few days, whence he sailed Aug. 2, and on Aug. 19, in lat. 41° 41' N., lon. 55° 48' W., discovered a ship to leeward, which was soon made out to be an English frigate. The course of the *Constitution* was shaped to close with this vessel, which hove to to await an engagement. At 5 P. M. the English frigate opened her fire at very long range, and at a little after 6 the *Constitution* closed with her. After a desperate fight of about half an hour the English frigate was reduced to a wreck and surrendered. She proved to be the *Guerriere*, Capt. Dacres, one of the ships which had recently chased the *Constitution*. Possession was taken of her soon after 7 P. M. The next

day she was discovered to be in a sinking condition, and after the removal of the prisoners she was set on fire and soon afterward blew up. The Constitution suffered somewhat aloft in this action, though but little in her hull. Her loss in killed and wounded was 14, and that of the Guerriere 79. The Constitution was the larger and heavier ship, mounting 54 guns, long 24s and 32-pounder carronades, the Guerriere mounting 49 guns, long 18s and 32-pounder carronades. As this was the first naval action of the war, it was regarded as very important. Capt. Hull carried his prisoners into Boston, where he was enthusiastically received. Congress at its next session presented a gold medal to him, and silver ones to each commissioned officer under his command in this engagement. After the war his principal services were in command of the navy yards at Boston and Washington, of the squadrons in the Pacific and Mediterranean, and in the board of navy commissioners.

HULL, William, an American soldier, born in Derby, Conn., June 24, 1753, died in Newton, Mass., Nov. 29, 1825. He graduated at Yale college in 1772, studied law at Litchfield, Conn., and was admitted to the bar in 1775. He entered the army of the revolution at Cambridge in 1775 as captain of a Connecticut company of volunteers; was made major in the 8th Massachusetts regiment in 1777, and lieutenant colonel in 1779, and was inspector of the army under Baron Steuben. He was in the battles at White Plains, Trenton, Princeton, Stillwater, Saratoga, Monmouth, and Stony Point. He commanded the expedition against Morrisania, for which he received the thanks of Washington and of congress. After the war he was major general of the 3d division of Massachusetts militia, and a state senator, and was appointed by Jefferson governor of Michigan territory in 1805. He remained in this office till 1812, when he was appointed as brigadier general to the command of the northwestern army. He marched his troops through the wilderness to Detroit, heard of the declaration of war, and of the fall of Michilimackinac, which let loose the Indians of the northwest upon him, crossed into Canada, but found his communications cut off, recrossed, and on the arrival of Gen. Brock surrendered to that officer the post of Detroit and the territory. For this act he was tried two years after by a court martial, and sentenced to be shot. The execution of the sentence was remitted by the president in consideration of his age and revolutionary services. In 1824 Gen. Hull published a series of letters in defence of his conduct in this campaign. In 1848 a volume was published in New York on his revolutionary services and the campaign of 1812, written by his daughter, Mrs. Maria Campbell of Georgia, and his grandson, the Rev. James F. Clarke of Massachusetts.

HULLAH, John, an English composer and teacher of music, born in Worcester in 1812.

His comic opera "The Village Coquettes," written in conjunction with Dickens, and produced in 1836, first made him known to the public. After the production of two other operas, he turned his attention about 1838 to the establishment in England of popular singing schools, similar to those which had proved so successful in Paris. In 1847 a spacious music hall was erected in London for his concerts, which was burned down in 1860. He is professor of vocal music and harmony in King's, Queen's, and Bedford colleges, London, organist of the Charterhouse, conductor of the orchestra and chorus in the royal academy of music, and musical inspector for the United Kingdom. He is the author of numerous works, essays, and lectures on the science and history of music.

HULTSCH, Friedrich Otto, a German philologist, born in Dresden, July 22, 1833. He became a teacher at Leipsic in 1857, subsequently at Zwickau, and afterward at Dresden, where in 1868 he became rector of the Kreuzschule. His principal works are *Griechische und römische Metrologie* (Berlin, 1862), and editions of the *Scriptores Metrologici* (Leipsic, 1864-'6), of Heron's *Geometrici et Stereometrici* (Berlin, 1864), of Censorinus *De Die Natali* (Leipsic, 1867), and of the "Histories" of Polybius (Berlin, 1867-'72).

HUMBER, a river or estuary of England, separating the counties of York and Lincoln. It is principally formed by the junction of the Ouse and the Trent. Its course is nearly E. as far as Hull, and S. E. thence to where it falls into the North sea. It is about 40 m. in length, and varies in breadth from 2 to 7 m. The chief towns on its banks are Hull, Goole, and Great Grimsby. By means of its numerous tributaries it drains an area of 10,000 sq. m. It is navigable for the largest ships to Hull, 20 m. from the sea, and throughout for vessels of considerable burden.

HUMBOLDT. I. A N. W. central county of Iowa, intersected by the Des Moines river and its W. branch; area, 576 sq. m.; pop. in 1870, 2,596. It has an undulating surface and a fertile soil. There are quarries of good building stone. The chief productions in 1870 were 59,101 bushels of wheat, 107,950 of Indian corn, 60,316 of oats, 12,416 of potatoes, 83,985 lbs. of butter, and 9,133 tons of hay. There were 999 horses, 1,021 milch cows, 1,614 other cattle, and 1,393 swine; 1 saw mill, and 2 flour mills. Capital, Dakota City. **II.** A N. W. county of California, bordering on the Pacific, and drained by Eel, Mad, and Bear rivers, and other streams; area, 2,800 sq. m.; pop. in 1870, 6,140. Humboldt bay lies near the N. W. corner, and Cape Mendocino, the westernmost point of the state, projects into the Pacific near the centre of the coast line. The surface is mountainous, and mostly covered with forests of redwood, pine, spruce, &c., which attain an enormous size. The bottom lands are fertile, but lumber is the chief source

of wealth. Petroleum has been found in the S. part. The streams swarm with salmon. The chief productions in 1870 were 32,284 bushels of wheat, 137,022 of oats, 31,907 of barley, 54,316 of peas and beans, 372,924 of potatoes, 112,580 lbs. of butter, 51,867 of wool, and 7,426 tons of hay. There were 4,329 horses, 5,691 milch cows, 12,056 other cattle, 12,660 sheep, and 10,050 swine; 3 manufactories of carriages, 1 flour mill, and 8 saw mills. Capital, Eureka. **III.** A N. W. county of Nevada, bordering on Oregon; area, 19,000 sq. m.; pop. in 1870, 1,916, of whom 220 were Chinese. The surface is generally mountainous, the E. portion being occupied by the Humboldt range. Humboldt, Reese, and Quins rivers, and other streams that lose themselves in "sinks," or lakes without outlet, water portions of the county. There are several lakes in the W. part. On Humboldt river and in Paradise and other valleys is some arable land, and the hills afford grazing; but the chief wealth is in the silver mines, which are mostly S. of the Humboldt river. Gold, copper, and lead are also found. By the census of 1870, 14 mines were returned, of which 12 were of silver, 1 of gold, and 1 of lead. There were 10 quartz mills, all except one for the production of silver. It is traversed by the Central Pacific railroad. The chief productions were 4,419 bushels of wheat, 30,209 of barley, 5,504 of potatoes, and 2,219 tons of hay. There were 365 horses, 2,186 cattle, 700 sheep, and 786 swine. Capital, Unionville.

HUMBOLDT, Friedrich Heinrich Alexander von, baron, a German naturalist, born in Berlin, Sept. 14, 1769, died there, May 6, 1859. He was less than ten years old at the death of his father, who had been adjutant of Duke Ferdinand of Brunswick in the seven years' war, and afterward a Prussian royal councillor. He and his elder brother Wilhelm were educated at home, with special care in the natural sciences. In 1787 he studied at the university of Frankfurt-on-the-Oder, returned to Berlin in the following year, and applied himself to the technology of manufactures and to the Greek language. An acquaintance with the botanist Willdenow led him to study the cryptogamous plants and the family of grasses. He passed a year (1789-'90) at the university of Göttingen, studying philology under Heyne, and extending his knowledge of natural history under the guidance of Blumenbach, Lichtenberg, and others. His first published work, the fruit of an excursion from the university, was *Ueber die Basalte am Rhein, nebst Untersuchungen über Syenit und Basanit der Alten* (Berlin, 1790). A rapid journey which he made in 1790, in company with George Forster, through the Low Countries, England, and France, gave him a desire to visit the tropics. He returned to Germany with the purpose of devoting himself to finance, and repaired to a mercantile academy at Hamburg, where he learned bookkeeping, familiarized himself

with counting-house affairs, and practised the modern languages. On a visit to his mother in the following year he obtained permission to engage in practical mining; and he went to the mining academy at Freiberg, where for eight months he enjoyed the private instruction of Werner and the friendship of Freiesleben, Von Buch, and Del Rio, the last of whom 12 years later he found settled in Mexico. He wrote while there a description of the subterranean flora and an account of his experiments on the color of plants withdrawn from the light and surrounded by irrespirable gases, entitled *Flora Subterranea Freibergensis, et Aphorismi ex Physiologia Chemica Plantarum*, which first appeared in 1793. With Freiesleben he made the first geognostic description of one of the Bohemian mountain ranges. In 1792 he was appointed assessor in the mining department, and subsequently became superior mining officer in the Fichtelgebirge. In 1793-'4 he explored the mining districts in Upper Bavaria, Galicia, and various parts of Prussia. In 1794 he accompanied the minister Hardenberg to Frankfurt, and was employed in his cabinet correspondence. On his return he experimented on the nature of fire-damp in mines. In 1795 he made a geognostic journey through Tyrol, Lombardy, and Switzerland. In 1796 he was sent on a mission to the headquarters of Gen. Moreau in Swabia. From the time when he first heard of Galvani's discovery he had accumulated materials for his work *Ueber die gereizte Muskel- und Nervenfasern, nebst Vermuthungen über den chemischen Process des Lebens in der Thier- und Pflanzenwelt* (2 vols., Berlin, 1797-'9). He also familiarized himself with practical astronomy, especially with the use of the sextant for determining geographical positions. On the death of his mother he resolved to prosecute his purpose of a great scientific expedition. Leaving Baireuth in 1797, he passed three months at Jena, and then began a second journey to Italy, with a desire to see the volcanoes Vesuvius, Stromboli, and Etna. The disturbed condition of Italy made his purpose impracticable, and he passed the winter in Salzburg and Berchtesgaden, occupied with meteorological observations. There he accepted the invitation of Lord Bristol to accompany him on an excursion to Upper Egypt, intending also to proceed to Syria and Palestine. He visited Paris to procure the requisite scientific instruments, but in May, 1798, he learned that Lord Bristol had been arrested at Milan charged with having secret political designs in Egypt. Remaining in Paris, he became intimate with the future companion of his travels, the young botanist Bonpland. At this time the public were interested in the voyage of circumnavigation which the directory had decreed and put under the command of Capt. Baudin. The expedition was to explore the E. and W. coasts of South America from Buenos Ayres to Panama, to

touch at many islands of the South sea, New Zealand, and Madagascar, and to return by the cape of Good Hope. Humboldt received permission to join the expedition, and to leave it when and where he wished. After several months of suspense, the necessities of war obliged the government to postpone the undertaking. Thus disappointed in his hopes of travel, Humboldt accepted an invitation to accompany the Swedish consul Skjöldebrand, who had been appointed to carry presents to the dey of Algiers, and he intended to proceed by way of Tunis to Egypt. The delay of the Swedish frigate, and the news from Barbary that during the war between the Turks and French every person arriving from a French port was thrown into prison, thwarted this purpose. He therefore, in company with Bonpland, resolved to spend the winter in Spain; and passing through Perpignan, Barcelona, Montserrat, and Valencia, making botanical, astronomical, and magnetic observations by the way, they reached Madrid in February, 1799. He was received with distinguished favor, and the Saxon minister at Madrid, Baron Forell, having overcome the scruples of the Spanish government and procured for him an interview with King Charles IV., all the Spanish possessions in Europe, America, and the East Indies were opened to him, with free permission to use all instruments for astronomical and geodetic observations, the measurement of mountains, the collection of objects of natural history, and investigations of every kind that might lead to the advancement of science. Such extensive privileges had never before been granted to any traveller. He left Madrid, measuring the elevations on his way through Old Castile, Leon, and Galicia, and on June 5, 1799, embarked with Bonpland in the frigate Pizarro from Corunna. Avoiding the English cruisers, they reached Tenerife on June 19, where they tarried to ascend the peak and to make many observations on the natural features of the island, and arrived at Cumaná, in Venezuela, July 16, 1799. After exploring the Venezuelan provinces for 18 months, residing the latter part of the time at Carácas, they set out for the interior from Puerto Cabello over the grassy plains of Calabozo to the river Apure, a branch of the Orinoco. In Indian canoes they made their way to the most southern post of the Spaniards, Fort San Carlos, on the Rio Negro, within two degrees of the equator. They could have advanced only by taking their boats over land, and therefore returned through the Cassiquiare to the Orinoco, which they followed to Angostura, proceeding thence to Cumaná. This journey through wild and unfrequented regions was the first which furnished any positive knowledge of the long disputed bifurcation of the Orinoco. They sailed to Havana, but after a few months hastened to seek some southern port, hearing a false report that Baudin, whom they had promised to join, had ap-

peared on the W. coast of South America. They embarked in March, 1801, from Batabanó, on the S. coast of Cuba. The season of the year forbade the execution of their plan of going to Cartagena and Panama, and they sailed for 54 days up the river Magdalena to Honda, in order to reach the high plateau of Bogotá. Thence they made excursions to the most remarkable natural features of the surrounding country. In September, 1801, in spite of the rainy season, they began to journey southward, passed Ibagua, the Cordillera de Quindiu (at an altitude of 12,000 ft., their highest encampment by night), Cartago, Popayan, Almaguer, and the lofty plain of Los Pastos, and reached Quito, after experiencing the greatest difficulties for four months, Jan. 6, 1802. The next five months they passed in investigations of the elevated vale of Quito, and of the snow-capped volcanoes which surround it, ascending some of these to heights not before attained. On Chimborazo they reached (June 23, 1802) the altitude of 19,286 ft., about 3,500 ft. higher than the point reached by La Condamine on the Corazon in 1738, and they were prevented only by a deep crevasse from advancing to the summit. They were joined at Quito by a young scholar, Carlos Montufar, son of the marquis of Selvalegre, who attended them throughout their wanderings in Peru and Mexico and back to Paris. Over the pass of the Andes in the paramo of Asuay, by Cuenca and Loja, they descended into the vale of the upper Amazon at Jaen de Bracamoras, and traversing the plateau of Cajamarca, by the mountain city Micuipampa (upward of 11,000 ft. high, near the silver mines of Chota), they reached the western declivity of the Peruvian Andes. From the summit of Guangamarca (about 9,500 ft. high) they enjoyed for the first time the long-sought view of the Pacific. They reached the coast at Trujillo, and travelled through the sandy deserts of Lower Peru to Lima. After one of the principal designs of their Peruvian journey, the observation of the transit of Mercury over the sun, was fulfilled, they embarked from Callao in December, 1802, and reached Acapulco in Mexico, March 23, 1803. They arrived in the city of Mexico in April, remained there a few months, and then visited Guanajuato and Valladolid, the province of Michoacan near the Pacific coast, and the volcano of Jorullo, which had first broken out in 1759, and returned by way of Toluca to the capital, where they remained long enough to arrange their rich collections and to reduce their various observations to order. In January, 1804, after having measured the volcano of Toluca and the Cofre de Perote, they descended through the oak forests of Jalapa to Vera Cruz, where they escaped from the then prevalent yellow fever. They compared their barometric measurement of the eastern declivity of the highland of Mexico with that which they had formerly completed of the western declivity, and made a profile

of the country from sea to sea, the first that was ever given of any entire country. On March 7, 1804, Humboldt sailed from the coast of Mexico for Havana, where during a two months' residence he completed the materials for his *Essai politique sur l'île de Cuba* (Paris, 1826). He embarked thence with Bonpland and Montufar for Philadelphia, enjoyed a friendly reception at Washington from President Jefferson, and leaving the new world landed at Bordeaux, Aug. 3, 1804, having spent five years in America, and gained a larger store of observations and collections in all departments of natural science, in geography, statistics, and ethnography, than all previous travellers. He selected Paris for his residence, and remained there till March, 1805, arranging his numerous collections and manuscripts, and experimenting with Gay-Lussac in the laboratory of the polytechnic school on the chemical elements of the atmosphere. He was accompanied by Gay-Lussac in a visit to Rome and Naples, and also by Von Buch on his return through Switzerland to Berlin, where, after an absence of nine years, he arrived Nov. 16, 1805. In the hope of modifying the ignominious treaty of Tilsit by negotiation, the government resolved in 1808 to send the young brother of the king, Prince William of Prussia, to the emperor Napoleon at Paris. During the French occupation of Berlin Humboldt had been busy in his garden, making hourly observations of the magnetic declination, and he now received the command of the king to accompany Prince William on his mission. As the condition of Germany made it impracticable to publish there his large scientific works, he was permitted by Frederick William III., as one of the eight foreign members of the French academy of sciences, to remain in Paris, which was his residence, excepting brief periods of absence, from 1808 to 1827. There appeared his *Voyage aux régions équinoxiales du nouveau monde* (3 vols. fol., with an atlas, Paris, 1809-'25; translated into German, 6 vols., Stuttgart, 1825-'32). When in 1810 his elder brother resigned the direction of educational affairs in Prussia to become ambassador at Vienna, the former post was urged upon Alexander von Humboldt; but he declined it, as the publication of his astronomical, zoological, and botanical works was not yet far advanced. He had also already decided upon a second scientific expedition through upper India, the region of the Himalaya, and Thibet, in preparation for which he was diligently learning the Persian language. He accepted from Count Rumiantzeff in 1812 an invitation to accompany a Russian expedition over Kashgar and Yarkand to the highlands of Thibet, but the outbreak of war between Russia and France caused the abandonment of the plan. The political events between the peace of Paris and the congress of Aix-la-Chapelle gave him occasion for several excursions. He went to England in the suite of

the king of Prussia in 1814, again in company with Arago when his brother Wilhelm was appointed ambassador to London, and again in 1818 with Valenciennes from Paris to London and from London to Aix-la-Chapelle, where the king and Hardenberg wished to have him near them during the congress. He also accompanied the king to the congress of Verona and thence to Rome and Naples, and in 1827, at the solicitation of the monarch, gave up his residence in Paris, and returned by way of London and Hamburg to Berlin, where in the following winter he delivered public lectures on the cosmos. In 1829 began a new era in his active career. He undertook, under the patronage of the czar Nicholas, an expedition to northern Asia, the Chinese Dzungaria, and the Caspian sea, which was magnificently fitted out by the influence of the minister, Count Cancrin. The exploration of mines of gold and platinum, the discovery of diamonds outside of the tropics, astronomical and magnetic observations, and geognostic and botanical collections, were the principal results of this undertaking, in which Humboldt was accompanied by Ehrenberg and Gustav Rose. Their course lay through Moscow, Kazan, and the ruins of old Bulgari to Yekaterinburg, the gold mines of the Ural, the platinum mines at Nizhni Tagilsk, Bogoslovsk, Verkhoturye, and Tobolsk, to Barnaul, Schlangenberg, and Ustkamengorsk in the Altai region, and thence to the Chinese frontier. From the snow-covered Altai mountains the travellers turned toward the southern part of the Ural range, and, attended by a body of armed Cossacks, traversed the great steppe of Ishim, passed through Petropavlovsk, Omsk, Miyask, the salt lake of Ilmen, Zlatusk, Taganai, Orenburg, Uralsk (the principal seat of the Uralian Cossacks), Saratov, Dubovka, Tzaritzyn, and the Moravian settlement Sarepta, to Astrakhan and the Caspian sea. They visited the Calmuck chieftain Sered Jab, and returned by Voronezh, Tula, and Moscow. The entire journey of over 10,000 miles was made in nine months; its results are given in Rose's *Mineralogisch-geognostische Reise nach dem Ural, Altai und dem Kaspischen Meere* (2 vols., Berlin, 1837-'42), and in Humboldt's *Asie centrale, recherches sur les chaînes de montagnes et la climatologie comparée* (3 vols., Paris, 1843; translated into German by Mahlmann, 2 vols., Berlin, 1843-'4). This expedition extended the knowledge of telluric magnetism, since in consequence of it the Russian imperial academy established a series of magnetic and meteorological stations from St. Petersburg to Peking, an example which was followed by the British government in the southern hemisphere. The convulsions of 1830 gave a more political direction to Humboldt's activity for several years, without interrupting his scientific career. He had accompanied the crown prince of Prussia in May, 1830, to Warsaw, to the last constitutional diet opened by the emperor Nicholas in per-

son, and he attended the king to the baths of Teplitz. On the news of the French revolution and the accession of Louis Philippe, he was selected to convey to Paris the Prussian recognition of the new monarch, and to send political advices to Berlin. The latter office fell to him again in 1834-'5, and he was called upon to fulfil it five times in the following twelve years, residing four or five months in Paris on each mission. To this period belongs the publication of his *Examen critique de la géographie du nouveau continent* (5 vols., Paris, 1835-'8; translated into German by Ideler, 5 vols., Berlin, 1836 *et seq.*). He made a rapid journey with King Frederick William IV. to England in 1841, to attend the baptism of the prince of Wales, to Denmark in 1845, and resided in Paris several months in 1847-'8, from which time he lived in Prussia, usually in Berlin, pursuing his scientific labors in his advanced age with undiminished zeal and energy.—Humboldt was distinguished, as a man of science, for the comprehensiveness of his researches, and especially for the skill and completeness with which he connected his own observations with all the stores of previous knowledge, and for the clearness with which he expounded facts in their relations. This tendency appeared in one of his earliest works on the contraction of the muscles and nerves, in which, after the progress of physiology for more than half a century, may still be seen the sagacity of his experiments on galvanism, and the truth of most of the inferences which he drew. In his travels he measured elevations, and investigated the nature of the soil and the thermometrical relations, at the same time collecting herbariums, and founding, by a combination of the materials in his hands, the new science of the geography of plants. Linnæus and some of his successors had observed some of the more palpable phenomena of the migrations of plants, without, however, considering elevation or temperature. It remained for Humboldt to bring together the vast series of facts collected from the most remote points, to combine them with his own observations, to show their connection with the laws of physics, and to develop the principles in accordance with which the infinitely numerous forms of the vegetable world have been spread over the earth. He was the first to see that this distribution is connected with the temperature of the air, as well as with the altitudes of the surface on which they grow, and he systematized his researches into a general exposition of the laws by which the distribution of plants is regulated. Connected with this subject he made those extensive investigations into the mean temperature of a large number of places on the surface of the globe which led to the drawing of the isothermal lines, so important in their influence in shaping physical geography and giving accuracy and simplicity to the mode of representing natural phenomena. By associating many important questions with bot-

any, he made it one of the most attractive of the natural sciences. He showed the powerful influence exercised by vegetable nature upon the soil, upon the character of a people, and upon the historical development of the human race. This view of the connection between the physical sciences and human history opened a path which has been followed by a school of subsequent investigators with novel and important results. Though wholly free from mystical meanings and obscure phraseology, his works are marked by poetical conceptions of nature wherever it is his aim to present broad and complete pictures. His delineations of the tropical countries give delight to readers who have no special knowledge of or interest in natural history. At the beginning of this century even the coasts of the immense Spanish colonies in America were scarcely known, and but little confidence was placed in the best maps. More than 700 places of which he made astronomical measurements were calculated anew by Oltmanns, whose work (2 vols., Paris, 1808-'10) forms the fourth part of Humboldt's "Travels." He himself made the map of the Orinoco and the Magdalena, and the greater part of the atlas of Mexico. He travelled with the barometer in his hands from Bogotá to Lima, ascended the peaks of Teneriffe, Chimborazo, and numerous other mountains, and made 459 measurements of altitude, which were often confirmed by trigonometrical calculations. His measurements in Germany and Siberia, combined with those made by other travellers, furnished valuable results to geography, and were the foundation of theories of the dispersion of plants and animals. Climatology was intimately connected with his researches. By his daily record of the meteorological, thermometrical, and electrical phenomena of the countries through which he passed, he instituted the science of comparative climatology. He was the first to entertain the idea of estimating the average elevation of continents above the sea, previous geographers and geologists having considered only the altitude of mountain chains and of the lower lands. His principal works in this department are: *Physique générale et géologie* (Paris, 1807); *Essai géognostique sur le gisement des roches dans les deux hémisphères* (1823-'6); and *Fragments de géologie et climatologie asiatique* (2 vols., 1831; translated into German by Löwenberg, Berlin, 1832). The phenomena of the volcanoes of South America and Italy he keenly observed and explained. With Bonpland he made very important observations on the sites, uses, and structure of plants. His principal botanical works are *Essai sur la géographie des plantes* (Paris, 1805), and *De Distributione Geographica Plantarum secundum Cæli Temperiem et Altitudinem Montium* (1817). The rich herbarium collected by him and Bonpland contained more than 5,000 species of phanerogamous plants, of which 3,500 were new. They were arranged and illustrated by Humboldt,

Bonpland, and Kunth, in the following works, which form the sixth part of his "Travels:" *Plantes équinoxiales, recueillies au Mexique, dans l'île de Cuba, &c.* (2 vols., 1809 et seq., with 144 plates); *Monographie des mélastômes et autres genres du même ordre* (2 vols., 1809-'23, with 120 colored plates); *Nova Genera et Species Plantarum, &c.* (7 vols., 1815-'25, with 700 plates); *Mimoses et autres plantes légumineuses du nouveau continent* (1819-'24, with 60 plates); *Synopsis Plantarum, &c.* (4 vols., 1822-'6); *Révision des graminées* (2 vols., 1829-'34, with 220 colored plates). The zoological results of his travels are contained in his *Recueil d'observations de zoologie et d'anatomie comparée* (2 vols., 1805-'32), in the publication of which he was aided by Cuvier, Latreille, and Valenciennes. Another costly work, the *Vues des Cordillères et monuments des peuples indigènes de l'Amérique* (1810, with 69 plates), contains elaborate pictures of the scenery of the Andes and of the monuments of the ancient civilization of the aborigines. The study of the great architectural works of the ancient Mexicans and Peruvians led Humboldt to investigations of their languages, records, early culture, and migrations. In this department his treatment was peculiar, for his *Essai politique sur le royaume de la Nouvelle Espagne* (2 vols., 1811) contained statistics united with the facts of natural history, and presented various doctrines of political economy from a new point of view. Especially original and influential were his reflections on the culture of the soil under different climates and on its effects upon civilization, and on the circulation of the precious metals. Besides his general works, he made many special investigations, as his treatise on the geography of the middle ages, in which he appears at once as historian, astronomer, and savant, his chemical labors with Gay-Lussac, his system of isothermal lines, his experiments on the gymnotus and on the respiration of fishes, and numerous contributions to physical geography. Soon after his return from America he gave a general sketch of the results of his inquiries in his *Ansichten der Natur* (Stuttgart, 1808), in which he aimed to present a picture of the physical world, exclusive of everything that relates to the turmoil of human society and the ambitions of individual men; and in the evening of his life he determined to give a systematic view of the results of his investigation and thought in the whole domain of natural science. This was the design of his *Kosmos* (5 vols., Stuttgart, 1845-'62), which explains the physical universe according to its dependencies and relations, grasps nature as a whole moved and animated by internal forces, and by a comprehensive description shows the unity which prevails amid its variety. He lived to complete this work, but the last volume was published after his death. It was translated into almost all the European languages, and has been without an equal in giving

an impulse to natural studies. To his personal influence is due nearly all that the Prussian government did for science in the latter part of his life. Agassiz says of him: "The personal influence he exerted upon science is incalculable. With him ends a great period in the history of science; a period to which Cuvier, Laplace, Arago, Gay-Lussac, De Candolle, and Robert Brown belonged." His personal habits were peculiar. He slept but four hours, rose at 6 in the winter and 5 in the summer, studied two hours, drank a cup of coffee, and returned to his study to answer letters, of which he received hundreds every day. From 12 to 2 he received visits, and then returned to study till the dinner hour. From 4 till 11 he passed at the table, generally in company with the king, but sometimes at the meeting of learned societies or in the company of friends. At 11 he retired to his study, and his best books are said to have been written at midnight. Many of the works of Humboldt are now almost inaccessible on account of their great cost. A new edition of his select works was published in Stuttgart in 1874, in 36 numbers, including *Kosmos*, with a biographical sketch by Bernhard von Cotta; *Ansichten der Natur*, with scientific explanations; and *Reise in die Aequinoctialgegenden des neuen Continents*, by Hermann Hauff, the only authorized German translation of this work. English translations of his "Travels," "Views of Nature," and "Kosmos" are contained in Bohn's "Scientific Library," of which they constitute nine volumes. The translation of "Kosmos" has been republished in New York in 5 vols. 12mo. The centenary of Humboldt's birth, Sept. 14, 1869, was celebrated in Germany and the United States, and eulogies were pronounced by many of the foremost scientific men of the day, among whom were Bastian, Dove, Ehrenberg, Virchow, and Agassiz. Many biographies of him have been published, the best being *Alexander von Humboldt, eine wissenschaftliche Biographie*, edited by Karl Bruhns, a joint production of Avé-Lallemant, Carus, A. and H. W. Dove, Ewald, Grisebach, Löwenberg, Peschel, Wiedemann, Wandt, and the editor, aided by the friends and relatives of Humboldt, and by the Prussian government (3 vols., Leipzig, 1872; English translation by Jane and Caroline Lassells, "Life of Alexander von Humboldt," 2 vols., London, 1872). See also his *Briefe an Varnhagen von Ense aus den Jahren 1827-'58*, published by Ludmille Assing, with extracts from Varnhagen's diaries (Leipzig, 1860); and *Les barons de Forell*, by Alexandre Daguet (Lausanne, 1873), containing many letters of Humboldt and an interesting account of his negotiations in Madrid for the exploration of the Spanish possessions in both hemispheres.

HUMBOLDT, Karl Wilhelm von, baron, a German scholar, brother of the preceding, born in Potsdam, June 22, 1767, died at Tegel, April 8, 1835. In 1788 he went to the university of

Frankfort-on-the-Oder, and thence to Göttingen, where he studied philology under the care of Heyne. He here became intimate with George Forster, and through him with Jacobi and Johannes von Müller. When the French revolution broke out, Wilhelm Humboldt, who had long been a reader of Rousseau, went to Paris (July, 1789), in company with Campe; and the result of his observations there was a great distrust of many theories and abstract ideas which he had previously held. Two years later he published his first work on the subject, a memoir in the *Berliner Monatschrift* (1792), entitled *Ideen über Staatsverfassung durch die neue französische Constitution veranlasst*, in which he combated the possibility of establishing a constitution on untried theories. He discussed the subject more fully at a later date in a separate book: *Idées sur un essai de déterminer les limites de l'action que doit exercer l'état*. After completing this work he laid it aside, judging the time inopportune for its publication, and afterward lost the manuscript, which was not found or published until after his death; but there is every reason to believe that he always entertained the opinions expressed in it. The keynote of the work is individual liberty. It presents a lofty ideal of the rights and duties of the individual, and of the dignity and nobleness to which human nature is able and ought to attain. The government which hinders individual development the least is to him the best. About this time philology and archæology had become prominent objects of investigation, and Humboldt, under the guidance of Heyne and Wolf, entered upon the study of Greek literature and art. An early result of his studies appeared in his "Essay on the Greeks" (1792). In July, 1791, he had married Caroline Dacheröden, a brilliant woman, who shared with him his Greek studies. In 1793, at Jena, he contracted with Schiller an intimacy which had great influence on his studies, the poet inducing him to apply himself more closely to philosophy and æsthetics. To this intimacy was added that of Goethe, who was then writing "Hermann and Dorothea." This work owed much to the criticisms and care of Humboldt, who not only superintended its printing, but wrote a commentary on it which ranks as a masterpiece of German criticism. In 1797, having lost his mother, he began his travels. After remaining with his family some time at Dresden, he went to Vienna and thence to Paris, where he arrived in November. He resided a year and a half in Paris, and then went to Spain, where he travelled during six months. At this time he was occupied with his system of comparative anthropology, or a philosophical history of mental development, in which every phase of literature should be traced to a corresponding civilization. This he based on philology, and his first studies were directed to the old Spanish languages, and particularly the Basque. He returned to Germany in 1801,

and was soon after appointed Prussian resident minister in Rome, where he distinguished himself as much in diplomacy as in letters. His knowledge of art enabled him to cultivate friendly personal relations, and his residence became a point of union for the most intelligent men in Rome. His letters to Goethe and Schiller, his translations of Pindar and Æschylus, and the poems written during this period, indicate great activity and versatility. In 1806 the defeat of Prussia at Jena rendered his political position a most trying one. He remained unwillingly at Rome during 1807, being desirous of contributing his aid to his country while recovering from its disasters. In 1808 he was recalled by family affairs, and was immediately appointed minister of state for the departments of religion, public education, and medical establishments. He was called under very trying circumstances, in January, 1809, to reorganize public instruction in Prussia; and the prominent position which that country at present holds in education is in a great measure due to him. In the midst of the apathy and despondency bordering on despair which at that time affected the people and government of Prussia, he succeeded in establishing the university of Berlin, and from its foundation until his death his contributions formed the chief glory of its transactions. All his reforms were effected during a period of general confusion, and in the face of opposition which demanded great firmness, and often severity. When they were fairly established, he reëntered the diplomatic service, and on June 14, 1810, was appointed minister at the court of Vienna. At Prague he met with the minister Stein, who was then flying from the pursuit of Napoleon, and with him concerted the part he was to take in the political struggles of the day. Stein had been greatly interested in the energetic reforms of Humboldt, and now gave him his full confidence. His task at the court of Vienna was to effect the reconciliation of Prussia and Austria, to consolidate the strength of Germany, and to excite it against Napoleon. The difficulty of the effort was greatly increased by the passive position assumed by Austria after the campaign of 1809, and the marriage of Maria Louisa to Napoleon in 1810. Finally in 1813, when Prussia rose against Napoleon, the conference of Prague was held. At this most critical period the perseverance of Humboldt succeeded in overcoming the hesitation of Metternich. Stein, at least, declared that the new course taken by Austria was entirely due to Humboldt, and Talleyrand said of him that there were not in all Europe three statesmen of his ability. He manifested the same shrewdness, reserve, and energy at the conferences of 1813-'15 at Frankfort, Châtillon, Paris, and the congress of Vienna. But with the formation of the treaty known as the "holy alliance" Humboldt had nothing to do, the emperor of Russia insisting that the king of Prus-

sia should not permit Humboldt to know anything of the treaty until it was concluded. During his diplomatic career he showed great genius in debate, quickness of reply, and a most delicate, cutting irony. In 1816 he went to Frankfort as ambassador, and in 1818 to London and Aix-la-Chapelle. In 1819 he was called to the ministry. At this time the king of Prussia determined not to introduce the representative system which he had promised to the people. Other points of difficulty arose, and Humboldt disagreed with his colleagues. By a decree of Dec. 31, 1819, he was dismissed from the ministry and deprived of his state appointments. He now retired to private life, and devoted himself to literature. His contributions to philology from this time were very extensive, and of such importance that it has been said that before him great minds, such as Herder, Adelung, and Friedrich Schlegel, had led the way, but Humboldt was the first who made of philology a science. Having formed the intention to follow all the languages of the Pacific in detail in order to establish the connection between India and Europe, he began with his work *Ueber die Kavisprache auf der Insel Java* (3 vols. 4to, Berlin, 1836-'40), in which he traces the languages, history, and literature of the Malay races. The most valuable portion of the work is its introduction, *Ueber die Verschiedenheit des menschlichen Sprachbaues und ihren Einfluss auf die geistige Entwicklung des Menschengeschlechts*. This was published separately (4to, Berlin, 1836), and embodies the conclusions at which he had arrived in regard to the origin, development, and nature of language in general. Besides this, his principal works are a number of criticisms collected in the *Aesthetische Versuche* (Brunswick, 1799); a translation of the "Agamemnon" of Æschylus, a work containing also valuable researches into the Greek language and metres; the *Berichtigungen und Zusätze zu Adelung's Mithridates* (Berlin, 1817); *Prüfung der Untersuchungen über die Urbewohner Spaniens, &c.* (1821); *Bhagavadghita* (1826); and *Ueber den Dualis* (1828). His collected works were published by his brother Alexander (7 vols. 8vo, Berlin, 1841-'52). His *Briefe an eine Freundin* (2 vols., Leipsic, 1847; 6th ed., 1856; and in 1 vol., 2d ed., 1863; English translation by Catharine M. A. Couper, 2 vols., London, 1849), containing his letters to Charlotte Diede, whose acquaintance he had made in Pyrmont in 1788, are renowned for beauty of thought and feeling. Among other English translations of his writings is "The Sphere and Duties of Government," by J. Coulthard (1854). The best biography of Wilhelm von Humboldt is by Haym (Berlin, 1856). His collection of MSS. and books he bequeathed to the royal library of Berlin.

HUMBOLDT RIVER, a stream which rises in the N. E. part of Nevada in Elko county, flows first W. by S., then bends N., and afterward

flowing S. S. W. loses itself after a winding course of about 300 m. in the Humboldt "sink" or lake, on the border of Humboldt and Churchill counties, in the W. part of the state. It is in no part more than a few yards wide, and is not navigable. It flows through a treeless region, the valley, except immediately along the stream, consisting of sandy land covered with sage brush, which, however, by irrigation might be rendered productive. Numerous streams on either side of the valley rush down the mountain gorges, but sink before reaching the Humboldt, except in the case of a few in seasons of more than usual snow and rain in the mountains. Of these streams the principal are the Little Humboldt on the north, and Reese river on the south. Near its source in Elko county, the Humboldt receives its N. and S. forks. As the only considerable stream flowing E. and W. through the Great Basin, its valley formed the ordinary emigrant route from the Great Salt lake to California; the Central Pacific railroad now follows its banks throughout its whole course. The Humboldt "sink" has no outlet, and is merely a marshy spot in a sandy plain, 10 or 15 m. long and 30 or 40 m. in circumference; the extent of water surface is variable, the capacity of the sands to absorb and of the atmosphere to evaporate being generally in excess of the supply from the river.

HUME, David, a Scottish historian, born in Edinburgh, April 26, 1711, died there, Aug. 25, 1776. His father, proprietor of the estate of Ninewells in Berwickshire, died during David's infancy, leaving three children. Hume was intended for the bar. He passed through the university of Edinburgh, but was drawn away from his legal studies by that love for literature which became the ruling passion of his life. At 16 he was a skeptic in matters of religion. His inheritance as a younger son being small, in 1734 he entered a counting room at Bristol, whence after a few months he passed over into France, and lived for three years with great economy while composing his "Treatise of Human Nature." In 1738 he printed his work in London, which, as he says, "fell dead born from the press." Returning to live at Ninewells, he printed anonymously at Edinburgh, in 1742, the first volume of his "Essays." He next sought a professorship in the Edinburgh university, but his skeptical principles prevented his success. In 1745 he went to live as companion to the insane marquis of Annandale. In 1746 Gen. St. Clair invited him to become his private secretary, in an expedition designed for the invasion of Canada, but which was finally directed against the coast of France. Hume was also made judge advocate in the army, and was highly popular with his military associates. When St. Clair went as minister to Turin, he took Hume with him as his secretary. On his way to Italy he passed through Germany, sailed down the Danube, and at Vienna was presented to the empress Maria Theresa. While at Turin, his "Inquiry con-

cerning the Human Understanding," a new casting of the unfortunate "Treatise," was printed at London. On his return from Italy in 1749, he lived with his brother and sister at Ninewells, his mother being now dead, and there wrote the "Inquiry concerning the Principles of Morals" and his "Political Discourses" (1752). In 1752, after strong opposition, he was chosen librarian of the advocates' library of Edinburgh, and now began his "History of England." The first volume of the "History of the House of Stuart," containing the reigns of James I. and Charles I., came out toward the end of 1754, and was unfavorably received. In 1756 he published a second volume, embracing the reigns of Charles II. and James II., which was better received. Hume had now formed a wide acquaintance among the professional and literary men of Scotland, his amiable manners and pure morals having conquered the prejudices excited by his skeptical opinions. The general assembly of 1755, however, condemned his writings, and even threatened him with excommunication. In 1757 appeared his "Natural History of Religion," which Dr. Hurd attacked in a violent pamphlet. Hume meanwhile became the patron of the rising literature of Scotland. He aided the blind poet Blacklock, and encouraged Wilkie, author of the "Epigoniad." Toward the end of 1758 he went to London to publish the "History of the House of Tudor." It appeared in 1759, and was severely criticised. In 1761 he published two volumes containing the earlier portion of the English annals. He proposed to write two more volumes to embrace the reigns of William III. and Anne, but this design was not fulfilled. By the sale of his copyrights he had now gathered a moderate fortune, and lived in Edinburgh in philosophic ease. But in 1763 the marquis of Hertford invited him to accompany him to Paris, where the marquis was appointed minister. Hume at first declined the invitation, but finally attended the marquis, and was received at Paris with signal distinction. The whole royal family, the French philosophers, the nobility, and particularly the ladies of high rank and fashion, overwhelmed him with their attentions; and Hume wrote to his friends in Scotland that Louis XIV. had never suffered so much flattery in three weeks as he had done. When Lord Hertford left Paris Hume became chargé d'affaires. In the beginning of 1766 he returned to England, bringing with him Rousseau, who sought there a refuge from persecution; he provided him with retired lodgings in Derbyshire, and obtained for him a pension from the king. But Rousseau soon afterward wrote a letter to Hume, accusing him of desiring to destroy his fame. Their quarrel made a great sensation, and Hume in self-defence published the letters that had passed between them. In 1766 Hume went to Edinburgh, but was invited by Gen. Conway the next year to become under secretary of state. He remained in London until Conway was superseded, and

in 1769 returned to Edinburgh. His income being now £1,000 a year, he engaged in building a house, and in the pleasures of society. In March, 1775, his health began to decline. The next spring he wrote a congratulatory letter to Gibbon, who had sent him the first volume of the "Decline and Fall." In April, 1776, he finished his "Own Life," a concise narrative of his literary career. After a journey to Bath he returned to Edinburgh to die. Five days before his death he wrote to the countess de Boufflers: "I see death gradually approach without any anxiety or regret." He was buried in Calton hill graveyard, Edinburgh, where a monument to him was erected. As a historian Hume holds a high rank among English writers. His narrative is interesting, his style clear, and with happy ease he blends profound thought, distinct portraiture, and skilful appeals to the feelings. He lacks, however, accuracy and impartiality. His philosophical writings do not form a complete system. He discussed detached questions of metaphysics, and aimed at the refutation of what he considered erroneous opinions rather than at the attainment of positive results. He regarded utility as the basis of morals, maintaining that the moral quality of actions was to be decided by their consequences. He asserts that the mind is conscious only of impressions and ideas, the latter following the former, and that there is no clearer proof of the existence of the mind than there is of matter. He traces the course of thought to the law of association, which he founds upon resemblance, contiguity, and cause and effect. But the doctrine of cause and effect is only a habit of the mind, resulting from experience. Thus all is uncertainty, and the mind reduced to skepticism. His history was continued by Smollett down to the death of George II., and after that by various authors. A new edition of his "Philosophical Works," edited by T. H. Green and T. H. Grose, has been commenced in London (4 vols., 1874 *et seq.*).—See "Life and Correspondence of David Hume," edited by John Hill Burton (2 vols., Edinburgh, 1847).

HUME, Joseph, a British statesman, born in Montrose, Scotland, in January, 1777, died in Burnley hall, Norfolk, Feb. 20, 1855. At about the age of nine he lost his father, the master of a small vessel, but was enabled by his mother, who established a crockery shop in Montrose, to receive a tolerable education. About 1790 he was placed with an apothecary of Montrose, and three years later he became a student of medicine at the university of Edinburgh, where he remained till 1796, when he was admitted a member of the college of surgeons of Edinburgh. Being appointed surgeon to an East Indiaman, he made two voyages to India, and in 1799 joined the medical establishment in Bengal. Finding that few of the company's servants had acquired the native languages, he applied himself to the study of them, and was soon able to speak them with fluency.

At the outbreak of the Mahratta war he was attached to the army, and upon a sudden emergency officiated as Persian interpreter with so much efficiency, that he was appointed to that office permanently. At the same time he was at the head of the medical staff, and for long periods acted as paymaster, postmaster, prize agent, and commissary general. These employments brought him reputation and emoluments; and in 1808 he was able to retire from professional life, and to return to England with a considerable fortune. For several years he devoted himself to travel and study. In January, 1812, he was for a valuable consideration returned to the house of commons for Weymouth and Melcombe Regis, commencing his political career as a tory. Before the parliament was dissolved, in the succeeding July, he opposed a ministerial measure for the relief of the Nottingham framework knitters, on the ground that the masters would be thereby so much injured that the workmen would be reduced to a worse state than before. This so alarmed the conservative patrons of his borough that at the next election they refused him a seat, although he had bargained for a second return. This proceeding probably opened the eyes of the new member to the evils of the borough system, for, although offered seats from other boroughs, he refused to enter parliament again except as a perfectly free member, a contingency which did not occur for several years. During this interval he busied himself with a variety of projects for the improvement of the laboring classes; but his chief efforts were directed against the abuses of the East India direction. In January, 1819, he reëntered parliament as a radical member for the Aberdeen district of burghs, comprehending his native town, Montrose. He continued to represent the Scotch burghs till 1830, when he was returned unopposed as one of the members for Middlesex. In 1837 he was defeated, but was immediately returned through the interest of Mr. O'Connell for Kilkenny, which he represented till 1841, when he was an unsuccessful candidate for the town of Leeds. In the succeeding year he offered himself once more to the electors of Montrose, in whose service he died. His legislative zeal and labors were hardly equalled by those of the most eminent of his contemporaries. He urged reforms in every department of government; and he lived to see the adoption of almost every important measure which he had advocated. In 1859 a statue of him was erected in his native town.

HUMMEL, Johann Nepomuk, a German composer, born in Presburg, Hungary, Nov. 17, 1778, died at Weimar, Oct. 17, 1837. At seven years of age he showed so much talent that Mozart assumed the direction of his musical studies. Later he received lessons in harmony, accompaniment, and counterpoint from Albrechtsberger, and valuable suggestions from Salieri. In 1803 he entered the service of Prince Ester-

házy, and composed his first mass, which won the approval of Haydn. From 1811 to 1816 he taught at Vienna, and after that was successively chapelmaster to the king of Würtemberg and the grand duke of Saxe-Weimar. He made many tours through Germany, France, Great Britain, and Russia, winning renown as a pianist. He excelled as a pianist, improvisator, and composer. His improvisations were remarkable for their originality and brilliancy, and were so carefully worked out as to have all the character of finished compositions. He took high rank as a composer, but it was unfortunate for his reputation that he was the contemporary of Beethoven, by whose genius he was overshadowed. He composed for the stage, the church, and the concert room. His compositions of the first class consist of operas, pantomimes, and ballets; of the second, of three masses for voice, organ, and orchestra. The third class is the most numerous, consisting of concerted pieces for various instruments, trios, quartets, quintets, and septets, with many works for the piano alone. He wrote also a complete pianoforte method, which in spite of its many merits has been superseded by later works in stricter relation to the requirements of modern art.

HUMMING BIRD, the common name of a large family (*trochilidae*) of beautiful slender-billed birds, found in America and its adjacent islands. There are three subfamilies, *grypinæ* or wedge-tailed humming birds, *lamporninæ* or curved-billed humming birds, and *trochilinæ* or straight-billed humming birds. The most brilliant species live in the tropical forests, amid the rich drapery of the orchids, whose magnificent blossoms rival the beauty of the birds themselves. As we leave the tropics their numbers decrease, and but a few species are found within the limits of the United States, some however reaching as high as lat. 57° N. In whatever latitude, their manners are the same; very quick and active, almost constantly on the wing, as they dart in the bright sun they display their brilliant colors. When hovering over a flower in which they are feeding, their wings are moved so rapidly that they become invisible, causing a humming sound, whence their common name, their bodies seeming suspended motionless in the air. They rarely alight on the ground, but perch readily on branches; bold and familiar, they frequent gardens in thickly settled localities, even entering rooms, and flitting without fear near passers by; they are very pugnacious, and will attack any intruder coming near their nests. The nest is delicate but compact, and lined with the softest vegetable downs; it is about an inch in diameter, and the same in depth, and placed on trees, shrubs, and reeds. The eggs, one or two in number, average about one half by one third of an inch, and are generally of a white color, and hatched in 10 or 12 days. It is very difficult to keep these birds in cages; but they have been kept in

rooms and conservatories for months, feeding on sugar or honey and water and the insects attracted by these, and have become so tame as to take their sweetened fluids from the end of the finger. They are incidentally honey eaters, but essentially insectivorous; their barbed and viscid tongue is admirably adapted for drawing insects from the depths of tubular flowers, over which they delight to hover. The family of *trochilidae* may be recognized by their diminutive size, gorgeous plumage, long, slender, and acute bill, but little cleft at the base, and peculiar tongue; the species are very numerous, probably as many as 400, some of which have a very limited range. The bill when closed forms a tube, through which the long, divided, and thread-like tongue may be protruded into deep flowers; there are no bristly feathers around its base, as in birds which catch insects on the wing; the tongue has its cornua elongated backward, passing around the back to the top of the skull, as in woodpeckers; the wings are long and falciform, with very strong shafts, the first quill of the ten the longest; the secondaries usually six; the tail is of various forms, but always strong, and important in directing the flight; the tarsi short and weak; the toes long and slender, and capable of sustaining them in a hanging position, as is known from their being not unfrequently found hanging dead from branches in the autumn after a sudden cold change in the weather.—The subfamily *grypinæ* have the bill slightly curved, and the tail long, broad, and wedge-shaped; of these

of perpetual snow, feeding upon the small hemipterous insects which resort to the flowers; *grypus* (Spix) is found in the neighborhood of Rio de Janeiro. The ruff-necked humming bird (*selasphorus rufus*, Swains.), of the western

parts of North America, is about $3\frac{1}{2}$ in. long, with a wedge-shaped tail; in the male the upper parts, lower tail coverts, and tail are cinnamon-colored, the latter edged or streaked with purplish brown; throat coppery red, with a ruff, and below it a white collar; in the female the back is greenish, and the metallic reflections are less brilliant. The Anna humming bird (*Atthis Anna*, Reich.) is somewhat larger, also inhabiting California and Mexico;

Ruff-necked Humming Bird (*Selasphorus rufus*).
1. Male. 2. Female.

the genus *phatornis* (Swains.) is found in the warmer parts of South America, and is numerous in species; *oreotrochilus* (Gould) inhabits the mountains of the western side of South America immediately beneath the line

Mango Humming Bird (*Lampornis mango*).
1. Male. 2. Female.

the tail is deeply forked; top of head, throat, and ruff metallic red, with purple reflections; rest of upper parts and band on breast green; tail purplish brown; in the female the tail is somewhat rounded, barred with black and

tipped with white, and the general color above metallic green. A second species of the last two genera is described by Prof. Baird in vol. ix. of the Pacific railroad reports.—The curved-billed humming birds, more than 100 species, are not represented in the United States, unless the mango humming bird (*Lampornis mango*, Swains.) be admitted; this may be distinguished from the common species by the absence of metallic scale-like feathers on the throat, and by the serrations of the end of the bill; the prevailing colors are metallic green and golden above, and velvety bluish black below, with a tuft of downy white feathers under the wings.—The common species throughout the eastern states, extending to the high central plains, and south to Brazil, is the ruby-throated humming bird (*Trochilus colubris*, Linn.). The length of this "glittering fragment of the rainbow" (as Audubon calls it) is about $3\frac{1}{4}$ in. with an extent of wings of $4\frac{1}{2}$

Ruby-throated Humming Bird (*Trochilus colubris*).

in.; the upper parts are uniform metallic green, with a ruby red gorget in the male, a white collar on the throat, and the deeply forked tail brownish violet; the female has not the red throat, and the tail is rounded, emarginate, and banded with black. The corresponding species on the Pacific coast is the black-crowned *T. Alexandri* (Bourc. and Mulsant). The last two belong to the subfamily of *trochilinae* or *mellisuginæ*, having straight bills; their genus is given by Gray as *mellisuga* (Briss.), of which there are more than 100 species. The largest of the humming birds belongs to this subfamily, and is the *hylocharis gigas* (Vieill.); it is nearly 8 in. long, brownish green above and light reddish below; the wings are longer than the deeply forked tail, and the general appearance is that of a brilliant swallow, with a long straight bill.—Those wishing to study in detail the complicated arrangement of this beautiful family are referred to the illustrated works of Lesson, Temminck, Audebert, and Vieillot,

and especially to Gould's monograph on the *trochilidae*; also to vols. xiv. and xv. of the "Naturalists' Library."

HUMPHREY, Heman, an American clergyman, born in Simsbury, Conn., March 26, 1779, died in Pittsfield, Mass., April 3, 1861. From the age of 16 he was engaged for several successive winters as a teacher in common schools. He graduated at Yale college in 1805, studied theology, and was pastor of the Congregational church in Fairfield, Conn., from 1807 to 1817, and in Pittsfield, Mass., from 1817 to October, 1823, when he became president of Amherst college, then unincorporated. Principally through his influence it obtained an act of incorporation the next year, and he presided over it till 1845, when he resigned, and devoted himself to literary pursuits, residing in Hatfield, Mass., and afterward in Pittsfield. He was one of the earliest advocates of the temperance cause. In 1810 he preached six sermons on intemperance, and in 1813 drew up a report to the Fairfield consociation which is believed to have been the earliest tract on the subject. Among his writings are: a prize essay on "The Sabbath" (1830); "Tour in France, Great Britain, and Belgium" (2 vols. 12mo, New York, 1838); "Domestic Education" (1840); "Letters to a Son in the Ministry" (Amherst, 1845); "Life and Writings of N. W. Fiske" (1850); "Life and Writings of T. H. Gallaudet" (1857); "Sketches of the History of Revivals" (1859); and "Revival Sketches" (1860). A volume entitled "Memorial Sketches of Heman and Sophia Humphrey," by Z. M. Humphrey and Henry Neill, was printed for the use of the family.

HUMPHREYS, a N. W. county of Tennessee, bounded E. by Tennessee river, and intersected near its S. border by Duck river, a tributary of the former stream; area, 375 sq. m.; pop. in 1870, 9,326, of whom 1,295 were colored. The surface is moderately uneven, and the soil is fertile. The Nashville and Northwestern railroad passes through it. The chief productions in 1870 were 27,783 bushels of wheat, 491,355 of Indian corn, 29,967 of oats, 62,766 of peas and beans, 18,502 of Irish and 17,829 of sweet potatoes, 113,177 lbs. of tobacco, and 107 bales of cotton. There were 1,971 horses, 914 mules and asses, 2,355 milch cows, 4,488 other cattle, 8,937 sheep, and 18,418 swine; 1 manufactory of woollen goods, 1 of ground bark, 2 saw mills, 6 tanneries, and 5 currying establishments. Capital, Waverley.

HUMPHREYS, Andrew Atkinson, an American soldier, born in Pennsylvania about 1812. He graduated at West Point in 1831, and served mainly in topographical duty till 1836, when he resigned his commission in the army, and became a civil engineer in the United States service. In 1838 he was reappointed in the army, serving generally in the topographical department, and from 1844 to 1849 had charge of the coast survey office at Washington. In 1849-'50 he was engaged in making topographic

and hydrographic surveys of the delta of the Mississippi, continuing in general charge of the work till 1861, when he published a voluminous and very valuable "Report upon the Physics and Hydraulics of the Mississippi River." During the civil war he was on the staff of McClellan until his supersedure by Burnside, was made brevet colonel for his services in the battle of Fredericksburg, commanded a division at Chancellorsville and at Gettysburg, and after the last battle became chief of the staff of Gen. Meade, being appointed major general of volunteers, July 8, 1863. He took an active part in the campaigns of 1864 and 1865, succeeding Hancock in the command of the 2d corps. He was brevetted brigadier general in the regular army for gallant conduct at Gettysburg, and major general for services at the battle of Sailor's Creek, the closing battle of the war (April 7, 1865). From July to December, 1865, he commanded the district of Pennsylvania, and thereafter he was in charge of the examination of the Mississippi levees till August, 1866, when he was appointed chief of engineers of the United States army, with the rank of brigadier general.

HUMPHREYS, David, an American poet, born in Derby, Conn., in July, 1752, died in New Haven, Feb. 21, 1818. He was educated at Yale college, entered the army at the beginning of the revolutionary war, and in 1780 became a colonel and aide-de-camp to Washington. He resided more than a year with Washington after his retirement to Virginia, and again in 1788. He accompanied Jefferson to Europe as secretary of legation in 1784, was elected to the legislature of Connecticut in 1786, and was soon associated with Lemuel Hopkins, John Trumbull, and Joel Barlow in the composition of the "Anarchiad," a series of poems which appeared in the "New Haven Gazette" and the "Connecticut Magazine." These poems were satirized as being the production of "four bards with Scripture names." An edition of them, purporting to be "the first published in book form, edited, with notes and appendices, by Luther G. Riggs," was published at New Haven in 1861. Humphreys was minister to Lisbon from 1791 to 1797, and afterward minister to Spain till 1802, and on his return imported from Spain 100 merino sheep, and engaged in the manufacture of woollens. He held command of two Connecticut regiments in the war of 1812, after which he lived in retirement. His principal poems are: an "Address to the Armies of the United States" (1782); a "Poem on the Happiness of America;" a tragedy, entitled "The Widow of Malabar," translated from the French of Le Mierre; and a "Poem on Agriculture." His "Miscellaneous Works" (New York, 1790 and 1804) contain besides his poems a biography of Gen. Putnam and several orations and other prose compositions.

HUMUS (Lat. *humus*, the soil), vegetable mould, or the product of the decay of vegeta-

ble matter. When portions of a decayed stump or the decayed matter of peat is digested in a weak solution of caustic potash or soda, a brown liquid is formed, which on the addition of an acid deposits a dark brown precipitate. This is a mixture, according to Mulder, of three substances, which he considers as compounds of water, or of water and ammonia, with three different acids, viz.: 1, geic acid, $C_{20}H_{12}O_7$; 2, humic acid, $C_{20}H_{12}O_8$; 3, ulmic acid, $C_{20}H_{14}O_6$. It has been doubted, however, whether humus has so definite a composition. Mulder also found that the brown substances formed by the prolonged action of boiling dilute acids upon sugar resemble ulmic and humic acids derived from mould, both in chemical composition and properties. Humus may be regarded as in a state of continuous decomposition or eremacausis, a species of slow combustion (see **EREMACAUSIS**), in which the hydrogen of the vegetable matter is more rapidly removed by oxidation than the carbon, so that it contains an excess of the latter element. The formation of water, carbonic acid, and ammonia, and the elimination of mineral constituents in the decay of woody fibre is one cause of the beneficial action of vegetable manures in promoting the growth of plants.

HUMUYA, a river of Honduras, rising at the S. extremity of the plain of Comayagua, and flowing due N. for a distance of about 100 m. to a point N. of the town of Yojoa, where it unites with the rivers Blanco and Santiago or Venta, forming the great river Uluu, which falls into the bay of Honduras, about 25 m. N. E. of the port of Omoa. For the greater part of its course it is a rapid stream, and only navigable for canoes. It is principally interesting in connection with the interoceanic railway through Honduras, in course of construction (1874) through its valley. Comayagua, the capital of Honduras, stands on its E. bank.

HUNDRED, the name given in some parts of England to the subdivision of a shire, which may have received the appellation from having comprised 100 families, 100 warriors, or 100 manors. The existing divisions of this name differ greatly in area and population. The hundred is by some considered to have been a Danish institution, adopted by King Alfred about 897, each county being divided into tithings, of which 10 or 12 made a hundred, presided over by a decanus, head borough, or hundred man. The hundreds were represented in the "shiremote," which, under the presidency of its earl and bishop or sheriff, regulated the affairs of the county. The jurisdiction of the hundred was vested in the sheriff, although it was sometimes a special grant from the crown to individuals, and he or his deputy held a court baron, or court leet. The hundred was held responsible for felons until delivered up.—The townships of the state of Delaware are called hundreds.

HUNFALVY. I. Pál, a Hungarian philologist, born at Nagy-Szálok, March 12, 1810. He

became in 1842 professor of jurisprudence at Kásmark, was a member of the Hungarian diet of 1848-'9, and has since lived in Pesth. He has written and edited a number of philological and ethnological publications, including *Chrestomathia Fennica* (Pesth, 1861), and "The Land of the Voguls" (3 vols., 1863), after the accounts of the Hungarian traveller Reguly. **II. János**, a Hungarian geographer, brother of the preceding, born at Gross-Schlagendorf, June 8, 1820. He became in 1846 professor of statistics and history at Kásmark, took part in the revolutionary movement of 1848-'9, and was imprisoned, but in 1850 resumed his duties at Kásmark, and was subsequently suspended for advocating the independence of Protestant education. He removed to Pesth in 1853, and became professor of statistics, geography, and history at the polytechnic institute of Buda. His works include a "Universal History" (3 vols., Pesth, 2d ed., 1862), "Physical Geography of Hungary" (3 vols., 1863-'66), the text to the pictorial work "Hungary and Transylvania" (3 vols., Darmstadt, 1859-'64), and a Hungarian edition of the "Travels" of Ladislas Magyar (Pesth, 1859).

HUNGARY (Hung. *Magyarország*, Magyar land; Ger. *Ungarn*), a country of Europe, formerly an independent kingdom, subsequently united with Austria, from 1849 to 1867 a crown-land or province of the latter, and since 1867 one of the two main divisions of the Austro-Hungarian monarchy. Before 1849 it embraced in a constitutional sense, besides Hungary proper, Croatia, Slavonia, and the Hungarian Littorale (coast land on the Adriatic), and in its widest acceptation also Transylvania, the Military Frontier, and Dalmatia, with an aggregate population of about 15,000,000. All these dependencies were in 1849 detached, and besides them from Hungary proper the counties of Middle Szolnok, Zaránd, and Kraszna, and the district of Kóvár, to be reunited with Transylvania, and the counties of Bács, Torontál, Temes, and Krassó, to form the new crown-land of the Servian Waywodeship and Banat. In 1867 the changes made in 1849 were repealed; the Waywodeship was abolished, Transylvania reunited with Hungary, and Croatia and Slavonia recognized as a dependency of the Hungarian crown, which has its own provincial assembly, but also sends deputies to the Hungarian diet, and is subordinate to the Hungarian ministry. The Military Frontier, which formerly had its separate administration, was destined to gradual incorporation partly with Hungary proper and partly with Croatia. Dalmatia was united with Cisleithan Austria. Thus Hungary in the wider sense, also called Transleithania or Transleithan Austria, from the little river Leitha which constitutes part of the frontier between the two main divisions of the monarchy, now comprises (the reorganization of the Military Frontier having become complete in 1873) Hungary proper, Transyl-

vania, Croatia and Slavonia, and Fiume. The lands of the Hungarian crown have in common with Cisleithan Austria an imperial ministry, consisting of the departments of foreign affairs and the imperial house, of finances, and of war. In the article AUSTRIA we have treated of the Austro-Hungarian monarchy as a whole; and the articles CROATIA, MILITARY FRONTIER, SLAVONIA, and TRANSYLVANIA will contain what is or lately was peculiar to those sections. In this article we shall treat of the lands of the Hungarian crown with special reference to that section which is called Hungary proper. Hungary (in the wider sense) is situated between lat. 44° 11' and 49° 35' N., and lon. 14° 25' and 26° 30' E., and is bounded N. E., N., and W. by Cisleithan Austria, S. and E. by the Turkish provinces and dependencies Bosnia, Servia, and Roumania. The total area of the lands of the Hungarian crown is 125,045 sq. m., of which 87,045 belong to Hungary proper. The population, according to the census of 1869, was 15,509,455, of whom 11,530,397 lived in Hungary proper.—Hungary in its chief parts forms a large basin surrounded almost entirely by mountain ranges, of which the principal are: the Carpathians, which encircle the north, with their various offshoots, the Hungarian Ore mountains between the Waag and the Eipel, the Mátra E. of the preceding, and the wine-growing Hegyalja between the Theiss and the Hernád; the Leitha range, the wooded Bakony, and the Vértes, mostly continuations of the Noric and Carnic Alps, in the S. W. division; and the Transylvanian Alps on the S. E. frontier. The chief artery of the country is the Danube, which enters it between Vienna and Presburg, and on its course to the Black sea receives the waters of all the other rivers, excepting only the Poprád, which rises near the N. boundary and flows to the Vistula. The principal of these affluents of the Danube are: on the right, the Leitha, Raab, Sárviz, and the Drave, which separates Hungary proper from Slavonia, with the Mur, its affluent; on the left, the March, Waag, Neutra, Gran, Eipel, Theiss, and Temes. The Theiss rises in the northeast, in the county of Máramaros, and its chief affluents are the Bodrog, Hernád, Sajó, and Zagya on the right, and the Szamos, Körös, and Maros on the left. Most of the rivers of Croatia and Transylvania are also tributaries of the Danube; among others, the Save on the Turkish frontier and the Alt from Transylvania. The S. W. division, which has the fewest rivers, includes the two principal lakes of the country, the Balaton and the Neusiedler. Various marshes, moors, soda lakes, and swamps extend near the banks of the great rivers, especially of the Theiss. There are also numerous mountain lakes called "eyes of the sea," and caverns, of which that of Agtelek in the county of Gömör is the most remarkable. Extensive islands are formed by the branches of the Danube; among others, the Great Schütt and Csepel in its upper course. The climate is in general mild,

owing to the great northern barrier of the Carpathians. Often, when snow covers the northern mountain regions, the heat is considerable on the lowlands of the south, especially near the Maros. The climate of the great central plain resembles that of northern Italy; its sandy wastes, however, greatly contribute to the aridity of the summer winds. Blasts of wind and hailstorms are not unfrequent in the Carpathians. The spring is the most agreeable season, but the autumn often partakes of the character of the Indian summer in the United States.—The fertility of the soil, with the exception of several mountainous and sandy regions, is almost extraordinary. Among the vegetable productions are: the different species of grain, especially wheat, maize, hemp, flax, rapeseed, melons, often of immense size, apples, pears, apricots, and plums; cherries, mulberries, chestnuts, filberts, and walnuts; tobacco, which is now monopolized by the crown; wine of the most various kinds, including the Tokay of the Hegyalja; almonds, figs, and olives, on the southern border; anise, Turkish pepper, sweet wood, safflower, madder, and other dye plants; oaks, which yield large quantities of galls, the beech, fir, pine, ash, alder, and numerous other forest trees, often covering extensive tracts of land in the mountainous regions. Among the animals are the bear, wolf, lynx, wild cat, boar, chamois, marmot, deer, fox, hare; many fine breeds of horses and cattle (including buffaloes), dogs, sheep, and swine, the last of which are fattened in the forests on acorns. The birds comprise the golden and stone eagle, hawk, kite, bustard, heron, partridge, woodcock, nightingale, and lark. Fish, bees, and leeches abound. Of minerals, there are gold, iron, and copper in large quantities; silver, zinc, lead, coal, cobalt, nitre, antimony, arsenic, sulphur, alum, soda, saltpetre, potassium, marble, crystal, chalk; salt in immense mines, especially in Mármaros; jasper, chalcidony, hyacinths, amethysts, agates, and beautiful varieties of opal (in Sáros). There are more than 300 mineral springs, of which those of Buda, Trentschin, Pöstény, Bartfeld, Parád, and Szobráncz are among the most renowned. The chief articles of export are wheat, rapeseed, galls, honey, wax, wine, tobacco, copper, alum, potash, wood, cattle, sheep, swine, hides, wool, dried fruits, and brandies, especially *slivovitz*a or plum liquor. For imports and manufactures Hungary relies mainly on Austria, the chief home manufactures, besides metals, being linen and woollens, leather, paper, pottery and clay pipes, soap and candles, and tobacco. The means of communication, formerly scanty, are now rapidly extending. Steamers ply on the Danube and Theiss; a network of railways connects the various parts of the country with each other and with the neighboring provinces. The principal seats of learning are at Pesth, which is also the literary centre, Presburg, Kaschau, Debreczin, Patak, Pápa, Erlau, Veszprém, Miskolcz, Sze-

gedin, Stuhl-Weissenburg, and Grosswardein. —The variety of nationalities and languages rivals that of productions. There are Magyars or Hungarians proper, the predominant race (according to the census of 1869, about 5,688,000 in the lands of the Hungarian crown, including the Szeklers of Transylvania; 5,024,000 in Hungary proper), chiefly in the fertile regions of the centre and in the southwest; Slovaks (1,841,000) in the mountain regions of the northwest and north; Ruthenians (448,000) in those of the northeast; Croats and Serbs (Rascians) in the south and southwest (about 2,405,700, of whom about 800,000 are in Hungary proper); Roumans in the southeast (about 2,477,700, of whom about 1,270,000 are in Hungary proper); Germans (1,894,800; in Hungary proper, 1,592,000) and Jews (552,000, mainly in Hungary proper), chiefly in the towns of all regions; gypsies (50,000), settled in towns and villages, or migratory; besides Armenians, French, Bulgarians, &c. These various elements are distinguished not only by language, but also by peculiar costumes, manners, and moral characteristics. Of the inhabitants in 1869, 7,558,000 (in Hungary proper, 5,933,000) were Roman Catholics, 1,599,000 (in Hungary proper, 981,000) united Greeks, 2,589,000 (in Hungary proper, 1,414,000) non-united Greeks, 2,031,000 (in Hungary proper, 1,720,000) Calvinists (Reformed, popularly Hungarian church), 1,113,000 (in Hungary proper, 887,000) Lutherans, and 552,000 Jews. Public education was reorganized in 1868. The common schools are of two grades: elementary schools with from one to three classes (14,685 in 1869), and schools of a higher grade with as many as six classes (569 in 1869). Education is compulsory, and children are bound to attend school from their 6th to their 12th year, and after that until their 15th year a "school of review." The actual attendance, however, is as yet unsatisfactory, and in 1869 amounted to only 50 per cent. of the children of school age, the number of attendants being 1,226,000. In 1869 there were 152 gymnasia, 25 *Realschulen*, and a university at Pesth. In 1872 a second university was opened at Klausenburg. —The Hungarian diet consists of two houses, the table of magnates and the table of deputies. The former in 1873 was composed of the 3 archdukes who had landed estates in Hungary, 31 Roman Catholic and Greek archbishops, bishops, and high church dignitaries, 12 imperial banner bearers, 57 presidents of counties, 5 supreme royal judges, the count of the Saxons in Transylvania, the governor of Fiume, 3 princes, 218 counts, 80 barons, and 3 "regalists" of Transylvania. The table of deputies had 444 members, of whom 334 belonged to Hungary proper, 75 to Transylvania, 1 to Fiume, and 34 to Croatia and Slavonia. The diet meets annually, and new elections must take place every three years. The right of voting belongs to all who have a regular business or pay a small amount of direct taxes,

as provided by law. The language of the diet is the Hungarian, but the representatives of Croatia and Slavonia are permitted to use the Croatian language. The Hungarian ministry consists of a president and the heads of nine departments, viz.: the ministry of national defence, the ministry near the king's person (*ad latus*), the ministry of finance, of the interior, of education and public worship, of justice, of public works, of agriculture, industry, and commerce, and for Croatia and Slavonia. The administration of communes was regulated by law in 1871; that of *municipia*, which class comprises counties, districts, and the royal free cities, in 1870. The supreme court of the kingdom is the royal *curia* in Pesth, consisting of two divisions, the court of cassation and the supreme court. The royal tables of Pesth (for Hungary proper and Fiume) and of Maros-Vásárhely (for Transylvania) are courts of the second resort; 102 royal courts and 306 district courts have original jurisdiction. The public revenue of Hungary for the year 1872 amounted to \$82,187,809, the expenditure to \$112,853,765. To meet the interest on the common debt of the monarchy contracted prior to 1868, Hungary pays an annual contribution of \$13,630,000. It has also a special debt amounting to \$219,000,000. Politically, Hungary proper, according to ancient custom, is divided into four natural divisions or circles, subdivided into counties, and called, from the standpoint of Pesth, the Cis-Danubian (N. and E. of the Danube), Trans-Danubian (S. and W. of the Danube), Cis-Tibiscan (N. and W. of the Theiss), and Trans-Tibiscan (S. and E. of the Theiss), and three districts: *Jazygia* (*Jászság*), with Great and Little Cumania (*Kunság*); the Hayduk towns (*Hajdu-Városok*); and *Kövár*. The counties are as follows: Cis-Danubian circle—Presburg (*Pozsony*), Neutra (*Nyitra*), Trentschin (*Trencsény*), Arva, Turócz, Bars, Liptó, Zólyom, Hont, Nógrád, Pesth (*Pest*), Gran (*Esztergom*), Bács. Trans-Danubian circle—Wieselburg (*Mosony*), Oedenburg (*Soprony*), Vas, Zala, Somogy, Baranya, Tolna, Veszprém, Raab (*Győr*), Comorn (*Komárom*), Weisenburg (*Fejér*). Cis-Tibiscan circle—Heves, Borsod, Gömör, Zips (*Szepes*), Sáros, Torna, Abauj, Zemplén, Ung, Bereg. Trans-Tibiscan circle—Ugocsa, Mármaros, Szatmár, Szabolcs, Bihar, Békés, Arad, Csanád, Csongrád, Torontál, Temes, Krassó, Middle Szolnok, Kraszna, Zaránd.—Among the nations who occupied parts of Hungary before its conquest by the Magyars or Hungarians, we find the Dacians, Illyrians, Pannonians, Bulgarians, Jazyges, Alans, Avars, Huns, Gepidæ, Longobards, and Khazars. The Romans held the S. W. part of the country under the name of Pannonia, while the S. E. belonged to their province of Dacia. Various Slavic tribes, together with Wallachs, Bulgarians, and Germans, were the chief occupants at the time of the Magyar invasion. The Magyars, a warlike people of the Turanian race, had made various migra-

tions, and long dwelt in the vicinity of the Caucasian mountains, and afterward in the region between the Don and the Dniester, before they approached and crossed the Carpathians (about 887) under the lead of Álmos, one of their seven chiefs (*vezér*), and elected head (*fejedelem*) or duke. They were divided into seven tribes and 108 families, had a compact, consecrated by oaths, which guaranteed justice and equality among themselves, and a religion which in various features resembled the Aryan element worship of the Medo-Persians, but also included the notion of a supreme being (*Isten*). Árpád, the son of Álmos, conquered the whole of Hungary and Transylvania, organized the government, and also made various expeditions beyond the limits of these countries, among others against Svatopluk of Moravia, being invited by Arnulf of Germany. These expeditions were further extended under his son Zoltán (907-946) and grandson Taksony (946-972), spreading terror and devastation as far as the North sea, the south of France and Italy, and the Euxine. But various bloody defeats, especially near Merseburg (933) by the emperor Henry I., on the Lech (955) by Otho I., and in Greece (970), finally broke the desire of the Hungarians for booty and adventurous exploits, and turned the attention of their princes to the consolidation of their power within the natural limits of the country. Gejza (972-997), the son of Taksony, who married a Christian princess, promoted the introduction of Christianity, which was almost completed under his son Stephen I. (997-1038), whose religious zeal gained him a crown and the title of apostolic king from Pope Sylvester II. (1000), and afterward the appellation of saint. Assisted by Roman priests and German knights, he proclaimed the freedom of Christian slaves, introduced Latin schools, established bishoprics, built churches, chapels, and convents, elevated the bishops to the foremost rank in the state, compelled the people to pay tithes to the new clergy, and subdued the rebellious adherents of the national religion. The political and administrative institutions of the state were also organized. The original equality of the conquerors was limited by imitations of the western feudal aristocracy. The higher clergy, the higher nobility, consisting of distinguished national families and of foreign lords, and the common nobility, embracing the bulk of the national warriors, were the ruling classes; the two former, together with the dignitaries of the state, the palatine (*nádor*), the court judge (afterward land judge), &c., formed the senate, or the higher division of the legislative body. Against this new and foreign order of things the national party more than once violently rose, both under Stephen and his successors, Peter (1038-'46), against whom Aba Samuel was elected king, and who twice lost his throne, Andrew I. (1046-'61), who perished after being defeated by his brother Béla, and Béla I. (1061-'63), under whom the resistance

of the defenders of the ancient religion was finally broken. The civil strifes were not only kept up by the undefined succession to the throne by the house of Árpád, but also fomented by the intervention of the popes and the emperors. The emperor Henry III. in the reign of Andrew repeatedly invaded the country. The son of the latter, Solomon (1063-'74), lost his throne chiefly in consequence of his ill treatment of his gallant cousins and successors Gejza (1074-'77) and Ladislas (1077-'95), to whom he owed his elevation, and some splendid victories over invaders; and he vainly applied for aid both to the emperor Henry IV. and his antagonist Pope Gregory VII., who each claimed the rights of suzerainty over Hungary. Solomon died in exile. Ladislas was equally brave and pious. He is a saint in the Roman calendar, and his victories over the Cumans, who invaded Transylvania and the neighboring districts, and the conquest of Croatia and Halicz (eastern Galicia), made him one of the favorite princes of his nation. His nephew Coloman (1095-1114), surnamed the Scholar, was an enlightened and able ruler. He introduced various reforms, refused to accept the lead of the first crusade, closely watched the hosts which passed through his country, and routed or repulsed the more disorderly, though he received Godfrey of Bouillon as a friend. He annexed Dalmatia, but stained the close of his reign by cruelty toward his brother Álmos, who conspired against him. His son, the profligate Stephen II. (1114-'31), waged war against almost all his neighbors. Béla II., the Blind (1131-'41), the son of Álmos, and like his father the victim of Coloman, took bloody revenge on his former enemies on the occasion of the diet at Arad. Under his son Gejza II. (1141-'61) numerous Saxon colonies were settled in Zips and Transylvania, while their countrymen who joined the second crusade desolated the regions through which they passed. The disputed rights to Galicia and Dalmatia, and the often changing relations with the Byzantine empire, were now sources of frequent wars in the north and south. Stephen III. (1161-'73), Gejza's youthful son, who overcame the intrigues of Manuel Comnenus and the opposition of two rivals, Ladislas II. and Stephen IV., but succumbed to poison, was succeeded by his brother Béla III. (1173-'96), who, having been educated at the Greek court, and supported by it, introduced various imitations of its administrative organization, and was successful in Galicia, as well as in Dalmatia against the republic of Venice. His connection with the West in consequence of his marriage with Margaret of France induced numerous noble youths to visit the chief cities and schools of France, England, and Italy. His son Emeric (1196-1205) was tormented by the revolts of his brother Andrew, and in vain had his son Ladislas III. crowned before his death. Andrew II. (1205-'35) was successively under

the influence of his unscrupulous wife, who finally was assassinated; of the pope, who compelled him to undertake a crusade; of his financiers, Christian, Saracen, and Jewish, who monopolized the revenues of the impoverished kingdom; of the nobility, who in 1222 extorted from him the "Golden Bull," a Hungarian Magna Charta of freedom and privileges, including the right of armed resistance to tyranny; and finally of a combined violent opposition, to which belonged his son and successor Béla (IV.). The long reign of the latter (1235-'70) commenced with salutary reforms, but was afterward disturbed by the immigration of the Cumans and the invasion of the Tartars, who annihilated the Hungarian army on the Sajó (1241), and marked their way from the Carpathians to the Adriatic by sword and fire, famine and pestilence. Béla did his best to restore order and repeople the country by new immigrants, bestowed various rights on the cities, and promoted the culture of the vine; but his wars with Austria, Styria, &c., and the revolts of his son Stephen, destroyed order, and promoted only the usurpations of the high nobility. Stephen V. (1270-'72) was successful against Ottokar of Bohemia. His son Ladislas IV. (1272-'90), who succeeded at the age of 10, caused violent commotions and endless misery by his Cumanian amours and predilections, and was murdered at the instigation of one of his mistresses. A nephew of Béla IV., Andrew III. (1290-1301), was the last of the Árpáds, and after a disturbed reign, which various diets held on the plain of Rákos near Pesth could not consolidate, died probably by poison. The throne was now open for competition, and the royal dignity became purely elective. Charles Robert of Anjou, a nephew of the king of Naples, and by his mother a descendant of the extinct dynasty, being supported by the see of Rome, was the first elected; while another party, the leader of which was the powerful count Matthias Csák, successively elected Wenceslas, son of the king of Bohemia (1301-'5), and Otho of Bavaria (1305-'8), both of whom were by a similar title descendants of the Árpáds. Charles Robert's reign (1309-'42) was marked by great successes at home and abroad. The regal power was extended and consolidated, chiefly by a new military and financial organization; western refinement and luxury made the Hungarian lords more docile, and the succession to the thrones of Poland and Naples was secured to the two sons of the king, Louis and Andrew. Visegrád, however, which replaced Stuhl-Weissenburg as the royal residence, witnessed many a princely crime. Buda became a still more splendid residence under Louis, surnamed the Great (1342-'82), who further developed the regal power, but with it the oppressive feudal institutions; and, excepting his repeated expeditions to Italy to revenge the assassination of his brother Andrew by his own wife, Joanna, he was successful in all his

undertakings, conquering among other territories Moldavia and Bulgaria. He also succeeded his uncle Casimir the Great, the last of the Piasts, as king of Poland. He was chivalrous, luxurious, and bigoted; he promoted commerce, but burdened the peasants, persecuted the Cuman pagans, and expelled the Jews, whom, however, his son-in-law Sigismund of Luxemburg brought back into the country. This prince having liberated his wife Mary, who had got rid of a rival, the Neapolitan Charles the Little, by assassination, but subsequently lost her throne and freedom, reigned together with her (1387-'95), and after her death alone (1395-1437), being also elected German emperor, and succeeding to the throne of his house in Bohemia. His long reign was full of civil strife, including the Hussite war in Bohemia, a revolt in Hungary, which for a short time deprived him of his liberty, and a rising of the peasants in Transylvania, and of wars against Venice and the Turks, who under Bajazet routed him in the battle of Nicopolis; but it was also marked by some salutary reforms in favor of the lower classes. Sigismund was succeeded by his son-in-law the emperor Albert (II.) of Hapsburg (1437-'9). He died after an unsuccessful campaign against Sultan Amurath, leaving his thrones to his wife Elizabeth, who offered her hand to Ladislas III. of Poland, a grandson of Louis the Great. The young Polish king after some struggle became also king of Hungary under the name of Uladislas I. (Hung. *Ulászló*), but, after several victories of his great general John Hunyady over the Turks, fell at Varna (1444), having broken his oath of peace to the infidels. Ladislas (V.), the posthumous child of Albert, whom his mother Elizabeth, shortly before her death, had carried together with the crown to her brother-in-law the emperor Frederick III., was now acknowledged as king (1445), Hunyady being appointed governor or regent. Frederick of Hapsburg, however, had to be compelled to restore the prince; powerful lords caused endless disturbances, and the Turks menaced Hungary, while preparing to strike the last blow at the Byzantine empire. Hunyady himself was defeated, but made good his escape, and died victorious, having repulsed Mohammed II., the conqueror of Constantinople, from the walls of Belgrade (1456). Of his two sons, Ladislas was executed by command of the ungrateful king, but Matthias, surnamed Corvinus, ascended the throne after the death of the latter (1457) and a protracted election struggle. The ablest monarch of Hungary (1458-'90), he subdued the rebellious lords, and in numerous campaigns vanquished the emperor, Podiebrad of Bohemia, and the armies of Mohammed II. He restored order, law, and prosperity, promoted science and art more than any other prince of his age, and administered his kingdom with an impartiality the glory of which survived him in the popular adage, "King Matthias is dead, justice gone." But his works

perished with him. The indolent Uladislas (II.) of Bohemia (1490-1516) was as poor as he was contemptible, and let his lords do as they chose. Of these John Zápolya, waywode of Transylvania, suppressed with dreadful bloodshed a great insurrection of the peasantry under Dózsa (1514). Under the young and weak son of Uladislas, Louis II. (1516-'26), the country gradually ripened for a catastrophe. While the nobles disputed, Belgrade fell, and finally the battle of Mohács was rashly fought against Sultan Solyman the Magnificent. The Hungarian army was destroyed, Louis perished on his flight, and his wife, the sister of Ferdinand of Austria, hastened to carry the crown to her brother. This prince inaugurated the still reigning dynasty of the Hapsburgs, being acknowledged as king (1527-'64) by the nobility of the western counties, while the national party elected John Zápolya, who prevailed in Transylvania and the adjoining parts. The latter put himself under the protection of Solyman, who took Buda and even besieged Vienna (1529). Long campaigns and negotiations and short-lived treaties now followed each other, the final result of which was that Hungary was for about 150 years divided into three parts with often changing limits, under the Hapsburgs as kings, the pashas of the sultans, and the princes of Transylvania. The greater part of Hungary proper, however, including the whole northwest, was in the hands of the royal or imperial armies, the monarchs holding also the crown of Germany after the abdication of Charles V., and finding many a hero among their Hungarian subjects. Maximilian (1564-'76) was saved by the self-sacrificing heroism of Zrinyi, who fell with his little fortress Sziget and the last of his men only after the death of the besieger Solyman and the destruction of a part of his army (1566). All these services of the magnates, as well as of the nation, were ill repaid by the Austrian dynasty. The diets of Hungary, which for centuries remained the blood-covered bulwark of Christendom, more than once had to complain that the imperial soldiery did more to devastate the country and famish the people than the infidel conquerors. Rudolph I. (1576-1608) commenced the persecution of the Protestants. These, however, not only had a free home in Transylvania under the enlightened Stephen Báthori, afterward king of Poland (who had succeeded the younger Zápolya), but also a protector of their rights in Hungary in Bocskay, the Transylvanian successor of Sigismund Báthori, who suddenly raised the banner of freedom, sweeping all over the north, crushing the generals of Rudolph, and finally compelling the latter to the humiliating peace of Vienna (1606). The old emperor finally resigned his Hungarian crown to his brother Matthias (II.), whose tolerant reign, however, was too short for the pacification of the country (1608-'19). His successor Ferdinand II. (1619-'37), who commenced his reign amid the first flames of the

thirty years' war, was prevented from tearing the Hungarian charter of liberty, as he did the Bohemian, by the victories of the Transylvanian prince Bethlen Gábor (Gabriel Bethlen), the successor of the profligate tyrant Gabriel Báthori, who extorted from him the treaty of Nikolsburg (1622), which again sanctioned the rights of the Protestants. A similar treaty was concluded at Linz by Ferdinand III. (1637-'57) with George I. Rákóczy of Transylvania (1645). Leopold I. (1657-1705), whose long reign in Hungary was but a series of wars, insurrections, and executions, found a less able opponent in the ambitious George II. Rákóczy of Transylvania, and excellent generals against the Turks in Montecuculi, who gained the battle of St. Gothard (1664), and Nicholas Zrinyi (the poet), but made an ignominious peace with the sultan, and sent against the insurgents of the northern counties the bloodthirsty Caraffa, Strasoldo, and others. The people rose again "for God and freedom" under Tökölyi (1678), who, being allied with Apafi of Transylvania, the Porte, and Louis XIV. of France, was near uniting the whole of Hungary under his banner, when the reverses of the Turks before Vienna (1683), and the subsequent victories of the imperialists, sealed the fate of the insurrection. Caraffa made the scaffold permanent in Eperies; the diet of Presburg had to consent to the demands of the emperor in making the throne hereditary in the house of Austria and abrogating the clause of the golden bull which guaranteed the right of resistance to oppression (1687); Prince Eugene completed the victories over the Turks, and conquered the peace of Carlovitz (1699); Transylvania was occupied, and Tökölyi, who tried in vain to recover it, died in exile in Asia Minor. Hungary was now a province of Austria, and treated as such, when the noble-hearted Francis Rákóczy, who had long lived in exile, suddenly appeared on the N. E. borders (1703) and renewed the struggle for religious and civil liberty. Protestants and Catholics flocked to his banners, which were triumphantly carried into the very vicinity of Vienna, when the emperor died. His son Joseph I. (1705-'11) was inclined to peace, and Rákóczy was not opposed to it, though assisted by Louis XIV. and the perplexities of the new emperor in the war of Spanish succession. Diets and negotiations followed each other, but without success, while the victories of Eugene and Marlborough and violent dissensions in the camp of the insurgents enabled the emperor to restore the fortunes of the war in Hungary. In the absence of Rákóczy, who had gone to Poland to procure the alliance of Peter the Great, a peace was finally concluded at Szatmár (1711) with the representatives of the emperor, toleration and a strict observance of the constitution being promised. Joseph's successor Charles (VI. as emperor, III. as king, 1711-'40) ratified the treaty, while Rákóczy absolved his followers from their oath of allegiance to him. The new emperor's favorite

scheme, the pragmatic sanction, which was to secure the succession of the female line to all his possessions, was agreed to by the diet of 1722, which also enacted various other important laws. The peace of Passarowitz (1718), the result of Eugene's new victories, enlarged the kingdom with the Banat, the last province of the Turks in Hungary; but after another war Belgrade was ceded to the Turks by the treaty concluded in that city in 1739. Charles's mild reign disposed the nation to defend the disputed rights of his daughter Maria Theresa (1740-'80), who appeared in person before the diet of Presburg, and was greeted with lively acclamations by the chivalric nobles. Their *Moriamur pro rege nostro Maria Theresa* was no vain promise, for Hungarian blood was shed profusely in her wars against Frederick the Great and other enemies. She rewarded the fidelity of the people by mildness, and various ameliorations of the condition of the peasantry (the *Urbarium*) are among the merits of her reign; but she too was far from strictly observing the constitution, which her son Joseph II. (1780-'90), in his immoderate zeal for reforms and centralization, was eager to destroy. To avoid binding himself by the constitutional oath, he refused to be crowned in Hungary, autocratically dictated his liberal reforms, and imposed upon the country foreign officials, a foreign language, the German, and foreign official costumes. But his violent though well meant measures were opposed everywhere, and the rising in his Belgic provinces, the unfavorable issue of his war against Turkey, and finally the threatening events in France, compelled the philanthropic despot to revoke his decrees shortly before his death. His mild and dissolute brother Leopold II. (1790-'92), afraid of the growing storm in the West, hastened to appease the Hungarian nation, which had been aroused by ignominious treatment and the spectacle of its perishing neighbor Poland to a general desire of national regeneration. The diet of 1791 again sanctioned the most essential constitutional rights of the kingdom in general, and of the Protestants in particular, and for a series of years Francis, the son and successor of Leopold (1792-1835), was satisfied during his wars with France with the continual subsidies of Hungary in money and men. The rare manifestations of democratic convictions he stifled in the dungeons of his fortresses, or, as in the case of the priest Martinovics (1795), in the blood of the offenders. The magnates were flattered and remained faithful. Thus Napoleon in vain called upon the Hungarians to rise for national independence (1809). Scarcely, however, was Napoleon fallen, when Francis's minister Metternich began to undermine the constitution of Hungary, the only check on the unlimited sway of the Austrian rulers. Every means, secret or open, was resorted to, but in vain. The progress of enlightenment, the warning example of Poland, and the spirit of nationality, re-

kindled by the activity of Francis Kazinczy and others, had prepared the nation for a struggle for constitutionalism and liberal reforms, which Metternich, both under Francis and his imbecile son Ferdinand V. (I. as emperor of Austria, 1835-'48), was unable effectively to resist. The Hungarian constitution had during the last few centuries undergone numerous modifications, without having at any period of its existence lost its vitality. As it was now, it was at the same time a charter of freedom, which shielded the people at large, and especially the non-Catholics, against bureaucratic sway, and secured to the nobility the greatest degree of personal liberty and immunity enjoyed by any class in Europe, and on the other hand an instrument of oppression in the hands of the nobility against all plebeian inhabitants of the country, especially the peasantry, which was degraded by numerous feudal burdens. The nobles were free from every tax and personal service, except in case of a hostile attack on the country itself, when they were obliged to rise in a body at their own expense; they enjoyed all the privileges of the right of *habeas corpus*, governed the counties by their regular assemblies ("congregations"), elected magistrates, and exercised the right of legislation by their deputies to the lower house of the diet. The higher nobility, or magnates, together with the chief dignitaries of the crown and the church, formed the upper house of the diet under the presidency of the palatine. The representation of the free royal towns was almost nominal. The diet was now regularly convoked by the monarch at Presburg, at intervals not exceeding three years. Its duration was unlimited. The chief royal organs of general administration were the Hungarian aulic chancery at Vienna, and the royal council at Buda, whose decisions, however, very often met with opposition or delay in the county assemblies. This *vis inertiae* of the latter was the principal check on all despotic or unconstitutional attempts of the Vienna ministry, while their publicity and jealously guarded freedom of debate were the chief elements of progress and political enlightenment. Gradually to abolish the immunity of the nobles and the feudal burdens of the peasantry, to endow the great bulk of the people with political rights, and at the same time to fortify the old bulwarks of the constitution, now became the task of the patriots; and the great movement offered the rare spectacle of an aristocracy contending for the abolition of privileges and the equality of the people. Paul Nagy and Count Stephen Széchenyi were the champions of nationality at the diet of 1825, which inaugurated a long period of moderate but gradual reforms, the most important of which were carried through at the diets of 1832-'6, 1839-'40, and 1843-'4. The rights of the non-noble citizens, peasantry, and Jews, the equality of the Christian confessions, the official use of the Hungarian language, and the freedom of speech were extended, the majority

of the educated lower nobility and a minority of the higher ardently contending against old abuses and aristocratic immunities, against bureaucratic despotism and religious intolerance. Among the leaders of the "liberal opposition" under Ferdinand were the members of the upper house Count Louis Batthyányi and Baron Eötvös; the deputies Deák, Beöthy, Klauzál, Ráday, Balogh, and Kubinyi; the Transylvanian agitator Baron Wesselényi, and the publicist Kossuth. The cabinet of Vienna chose the last five as its victims, prosecuting them for treason, and imprisoning Wesselényi and Kossuth for years. The old palatine Joseph, the uncle of the emperor, and the conservatives under the lead of Széchenyi and others, in vain strove to check the agitation. It reached its culminating point when Kossuth, after a lively struggle, was elected as representative of Pesth to the diet of 1847. A conflict with the government seemed imminent, when the general shock which followed the French revolution of February overthrew the rule of Metternich (March 13, 1848). Kossuth was greeted as liberator by the people of Vienna, and together with L. Batthyányi intrusted with the formation of an independent Hungarian ministry by Ferdinand. Pesth had its revolutionary *journal* on March 15. Batthyányi was president of the new ministry, Kossuth minister of finance. Having enacted the abolition of feudality, a new election law, and various other radical changes in the constitution, the last diet of Presburg dissolved, the new national assembly being appointed to meet in July at Pesth. The cabinet of Vienna commenced its intrigues against the new order of things on the very day when it sanctioned it. Jellachich and others were sent openly or secretly to organize insurrections among the southern Slavic tribes and the Wallachs and Saxons in Transylvania, the diet of which proclaimed its reunion with Hungary. Every new measure met with opposition or delay through the Vienna government or its tools. Negotiations had no result. The whole south of the country was soon in a flame. Croatia and Slavonia proclaimed their independence of Hungary, and Ban Jellachich occupied the Littorale, and threatened to cross the Drave. Against all these contingencies the only resource of the government was its own zeal and the enthusiasm of the people. Volunteer troops (*honvéds*, defenders of the land) were raised in the counties, contributions toward a national treasury were collected, and the militia was organized. The diet assembled in July and voted extensive levies and ample means for defence, but Ferdinand refused to sanction its resolutions. The Austrian troops which were still sent against the insurgents were led by traitors. A serious attempt under Mészáros against the Rascians in Bács (August) failed; the new troops were slowly gathering. Jellachich finally crossed the Drave, and the Vienna government, having reconquered Lombardy, threw

off its mask and sent Count Lamberg to disperse the diet by force. The Batthyányi ministry now resigned, and a committee of defence was formed under the presidency of Kossuth. The revolution began. The old troops were transformed and blended with the new. Kossuth's eloquence brought the people of the central plain under arms. Single detachments of Hungarian troops returned with or without their officers from abroad. The fortress Comorn was secured. The archduke Stephen, the new palatine, fled from the country. Lamberg was massacred on the bridge of Pesth by a mob. Jellachich was defeated at Pákozd near Buda (Sept. 29) and fled toward Vienna, which rose in revolution (Oct. 6). The principal fortresses hoisted the national flag. On the other hand, Temesvár and Arad hoisted that of Austria. The war of races raged with terrible fury and varying success. Transylvania was entirely lost. The pursuit of Jellachich was executed with hesitation by Móga, a late Austrian general, the frontier river Leitha was crossed too late, and the hastily collected volunteers fled after a short fight at Schwechat (Oct. 30) against Windischgrätz and Jellachich, who thus became masters of Vienna. Katona, sent to reconquer Transylvania, was routed at Dées. Count Schlick entered Hungary from the north, and occupied Kaschau (Dec. 11). The Rascian Damjanics alone led the honvéds to victory on the S. E. frontier, while Perczel successfully defended the line of the Drave on the S. W. Unable to defend the W. frontier against Windischgrätz, Görgey, the new commander of the army of the upper Danube, retreated on the right bank of that river, evacuating Presburg, Raab, and, after the rout of the equally retreating Perczel at Moor (Dec. 29) and an engagement at Tétény, the capital Buda-Pesth itself (Jan. 5, 1849). The day before, Schlick dispersed the undisciplined army of the north under Mézszáros, the minister of war. Thus the government and diet, which transferred their seat to Debreczin, would have had little prospect of security if the Polish general Bem had not begun in the latter half of December a new Transylvanian campaign, which cheered the patriots with a nearly unbroken series of successes over the imperialists. Görgey, too, who according to a new plan of operations returned westward on the left bank of the Danube, leaving a part of his troops with Perczel on the middle Theiss, succeeded in diverting the Austrian main army under Windischgrätz from a march on Debreczin. Then turning northward, he skilfully fought his way through the rugged region of the Ore mountains, amid continual perils, and, after a signal victory of his vanguard under Guyon over Schlick's corps on Mount Branyiskó (Feb. 5), finally effected a junction with the army of the upper Theiss, which under Klapka had been successful against that Austrian general. The activity of Kossuth and his associates in supplying all these bodies of troops with men, ammunition, money, and

officers was admirable. The zeal of the committee of defence was worthily responded to by the confidence of the people, who, even when two thirds of the country were in the hands of the enemy, almost as willingly accepted "Kossuth's bills" as specie, and by the general bravery of the troops. But new dangers arose with the invasion of the Russians from the Danubian principalities into Transylvania, where Bem, after a triumphant march (January), was suddenly checked before Hermannstadt, and could save his position at Piski (Feb. 9, 10) only after the loss of a part of his troops; and within the national camp by the stubborn disobedience and intrigues of Görgey, which caused the unfavorable issue of the great battle of Kápolna (Feb. 26, 27), the retreat of the united main army beyond the Theiss, the deposition of its commander, the Pole Dembinski, and a considerable loss of time. Another heavy loss was that of the isolated fortress Eszék, which was surrendered with immense stores by its cowardly commanders. Elated by the despatches of Prince Windischgrätz, the young emperor Francis Joseph, who had succeeded his uncle at Olmütz, Dec. 2, 1848, now promulgated a new constitution (March 4), which with one stroke annihilated the constitution and national independence of Hungary, making it, with narrowed limits, a crownland of Austria. But the next few days brought a new series of Hungarian victories. Damjanics, who had been recalled from the south, routed the Austrians at Szolnok (March 5). Bem took Hermannstadt and drove the Russians through the Red Tower pass into Wallachia. After the occupation of Cronstadt, all Transylvania, except Carlsburg, was in the hands of the Polish general. Perczel swept over the Rascian Vendée. The temporary chief commander of the main army, Vetter, having fallen ill, Görgey finally received the command, and the offensive against Windischgrätz was resumed. He crossed the Theiss at various points, and, advancing toward the capital, defeated the enemy at Hatvan (April 2), Bieske, Izsaszeg, Waitzen, and Nagy Sarló, rescued Comorn, which had withstood a long siege and bombardment, crossed the Danube, and gained a victory at Ács (April 26). During this short campaign the diet at Debreczin proclaimed the independence of the country (April 14), appointing Kossuth its governor, and Aulich entered Pesth. Instead, however, of continuing his victorious march to the capital of the enemy, Görgey returned with the bulk of his army to the siege of Buda, while a new and extensive Russian invasion was approaching. Buda was stormed (May 21), the government and diet returned to the capital, and Görgey again took the field, but injudiciously chose the N. bank of the Danube for his new campaign, and, without profiting by Kmetty's victory at Csorna, S. of that river (June 13), wasted the blood of his army on the Waag. The Russian armies and fresh Austrian troops under Hay-

nau were in the meanwhile pouring into the country from various quarters. Wysocki, the successor of Dembinski in command, retreated before Paskevitch; Temesvár was unsuccessfully besieged by Vécsey; Bem was paralyzed by a new and more terrible rising of the Wallachs, while his province, too, was invaded by the Russians. After various unsuccessful struggles on the line of the Waag, the loss of Raab, and a great battle at Szöny (July 2), Görgey, leaving Klapka in Comorn, finally retreated toward the middle Theiss; but after a bloody fight against Paskevitch at Waitzen (July 15), he turned northward, again and again repulsing the Russians, and crossed the Theiss at Tokay. The Russians crossed it at Fűred, while the central Hungarian forces under the chief command of Dembinski retreated toward Szegedin. The government, leaving the former place, where the last session of the diet had been held, retired to Arad, which, having recently surrendered, was made the last point of general concentration, after the rout of Bem at Schäsburg by the Russians under Lüders, of one of Görgey's divisions under Nagy-Sándor before Debreczin by the army of Paskevitch, and of Dembinski at Szőreg by Haynau. Dembinski, however, retreated toward Temesvár, where his army suffered a terrible defeat (Aug. 9). Görgey, who now arrived at Arad, summoned Kossuth to resign, and received from him the supreme civil and military command, Klapka's sally from Comorn and signal victory over the besieging Austrian army (Aug. 3) being unknown at Arad. Two days later Görgey surrendered his army at discretion to the generals of the czar at Világos (Aug. 13). Damjanics followed his example, and surrendered Arad. Kossuth, the late ministers Szemere and Casimir Batthyányi, the generals Bem, Dembinski, Mészáros, Vetter, Perczel, Guyon, Kmetty, Wysocki, and others, fled into Turkey. Munkács, Peterwardein, and Comorn capitulated. But scarcely had the tricolor disappeared from the ramparts of the last named fortress, Oct. 4, when the work of revenge commenced on the side of the victors. Count Louis Batthyányi, who had been made captive on a mission of peaceful mediation, was executed at Pesth, Oct. 6, and the commanders Kis, Aulich, Damjanics, Nagy-Sándor, Török, Lahner, Vécsey, Knézich, Pöltenberg, Leiningen, Schweidel, Dessewffy, and Lázár, all of whom had surrendered at discretion, were executed on the same day at Arad. Other executions followed. The dungeons of the empire were filled with prisoners for life or long terms. Görgey was confined at Klagenfurth. The remnants of the Hungarian troops were impressed into the Austrian army, and the estates of the rich patriots confiscated. The country remained under martial law, receiving new divisions, authorities, and tax regulations, and foreign officials. The German was made the language of the reorganized higher courts, offices, and schools. New contributions, military levies, and so-called

voluntary loans, followed each other. A conspiracy and an attempt on the emperor's life led to the resumption of wholesale executions in 1853. The Protestants and Jews were subjected to particular restrictions. This state of affairs ended with Austria's defeat in Italy (1859). The dismissal of the centralizing minister Bach, the appointment of Goluchowski, and the diploma of Oct. 20, 1860, were followed by the convocation of a Hungarian diet. This was opened in April, when Schmerling had taken the place of Goluchowski, and the patent of Feb. 26, 1861, that of the October diploma. (See AUSTRIA, vol. ii., pp. 149, 150.) As no representatives from Transylvania had been summoned, the diet considered itself incomplete, and this was to be expressed, together with other grievances, either by an address to Francis Joseph, as Deák proposed it, or merely by a resolution ignoring the royal rights of that emperor. When the debate was to open, May 8, the leading defender of the latter policy, Count Teleky, was found to have put an end to his career by a pistol shot. (See TELEKY.) Deák's address was carried, but as he emphatically demanded the restoration of the laws of 1848, the diet was dissolved in August. The country maintained its opposition to the Vienna schemes, and only the Saxons and Roumans of Transylvania were persuaded in 1863 to send representatives to the imperial Reichsrath. The joint intervention with Prussia in the Schleswig-Holstein affairs proving detrimental to Austria, chiefly from want of ready support on the part of the Hungarian and Slavic nationalities, Francis Joseph repaired to Pesth in June, 1865, dismissed Schmerling, replacing him by a federalist minister, Belcredi, suspended the imperial constitution, and convoked a new Hungarian diet. Deák ruled this as he did the preceding, and remained firm in his demands. Francis Joseph, on the eve of the great struggle with Prussia, prorogued the diet, but after the disastrous battle of Sadowa (July 3, 1866) was ready to submit to the demands of the Hungarians. His new leading minister Beust undertook the task of carrying through a compromise, and the result was the dualistic system of the Austro-Hungarian monarchy, as finally sanctioned in December, 1867. (See AUSTRIA, vol. ii., p. 141.) A national Hungarian ministry was appointed in February, 1867, of which Count Andrassy was the head. A general amnesty was proclaimed, and the emperor was crowned as king of Hungary (June 8) at Buda, with extraordinary pomp. The diet, having carried through various reforms, including the emancipation of the Jews, and settled the relations of Croatia to the Hungarian crown on a basis analogous to the relation of Hungary to the monarchy, closed its sittings in December, 1868. Two principal parliamentary parties had been formed, the conservative or Deák party, which had a decided majority, and the opposition party of the left, under Ghyecz and Tisza, aiming at a mere

personal union with Cisleithan Austria under the house of Hapsburg. The revolutionary extreme left numbered few adherents. The same was the position of affairs in the diet of 1869-72. Andrásy, who in the war of 1870 restrained Beust from interfering against Prussia, succeeded that statesman in November, 1871, as foreign minister of the monarchy, Lónyay taking his place in Hungary. A new agreement was entered into with Croatia, and the Military Frontier districts were gradually placed under civil jurisdiction. The finances of the country, however, became rapidly embarrassed by state subsidies, and Lónyay fell under personal attacks, Szlávy becoming his successor (December, 1872). The new cabinet was even less successful, and in March, 1874, made room for a coalition ministry under Bittó.

HUNGARY, Language and Literature of. The Hungarian language (Hung. *Magyar nyelv*) is an isolated branch of the Uralo-Altaic family, constituting a peculiar group with the now extinct idioms of the Uzes, Khazars, Petchenegs, and ancient Bulgarians. Leo Diaconus (10th century) called the Magyars Huns, and the people liked to consider themselves as such, being proud of Etele (Attila) and his brother Buda. The chronicle of the monastery of St. Wandrill and Dankovszki connect them both with the Huns and Avars. Some connect them with both the Ugurs and the westerly Ogors or Yugri. There are also various fanciful derivations of the name Magyar from roots belonging to the Hungarian language. The Byzantine emperor Constantine Porphyrogenitus names the people Turkoï. The Magyars and the Osmanlis agree in the belief that they are kindred, and the former are called "bad brothers" by the latter for having resisted them. Klaproth deduces the Hungarian language from a mixture of Tartaric or Turkish with Finnic. Malte-Brun considers the Magyars as Finns who were subjected to the Turks and to an unknown Uralian people. Bese found that Balkar tribes in the Caucasus boasted of being Magyars, and that the ruins of a Magyar town were yet visible S. W. of Astrakhan. Csoma de Kőrös, who went in search of the cradle of his nation, found many words in the Thibetan and other tongues of middle Asia akin in sound and sense to the Magyar, but was unable to solve the mystery of the original home of the race. Many Hungarian writers report that their ancestors brought from Asia works written in their national 34 characters, which were suppressed at the command of Pope Sylvester II. and with the aid of Stephen I., but which were taught as late as the beginning of our century in remote places among the Szeklers, and may be seen in S. Gyarmathy's grammar as well as in George Hickey's *Linguarum Veterum Septentrionalium Thesaurus* (3 vols. fol., Oxford, 1703-5), under the name of *Hunorum litteræ*. The language is now accommodated to the Latin alphabet, and consists of 26 simple and 6

compound sounds, agreeing, unless otherwise noticed, with the Italian, viz.: 8 vowels: *a* (like English *a* in *what*, *swallow*), *e*, *é* (French), *i* (also *y*), *o*, *u*, *ö* (Fr. *eu*), *ü* (Fr. *u*); 18 consonants: *b*, *d*, *f*, *g* hard, *h* (German), *j* (German), *k*, *l*, *m*, *n*, *p*, *r*, *s* (Eng. *sh*), *t*, *v* (also *w*), *z* (French), *sz* (Eng. *s*), *zs* (or 's, Fr. *j*); 4 compounds with *y*: *gy* (*dy*, as in *gyár*, factory, pron. *dyar*, in one syllable), *ly* (as in Fr. *fille*), *ny* (Fr. *gn*), *ty*; and 2 compound sibilants: *cs* (written also *ch*, *ts*; Eng. *tch*) and *cz*, *c*, or *tz* (Eng. *ts*). With the addition of the vowels marked as long with the acute accent, as for instance *á* (long Italian *a*), *é*, *ó*, *ú*, *ü*, there are 38 sounds in all, besides *x*, which is used only in foreign names, as in Xerxes. As in Turkish and other kindred tongues, the whole mass of words and grammatical forms is divided into two groups, viz., into those of high and low sound. The former is determined by the presence of *e*, *ö*, *ü*, the latter by that of *a*, *o*, *u*, in the roots or stems; those with *é* or *i* constitute a neutral ground. All formative and relative suffixes have therefore a double form, in harmony with the roots to which they are attached; thus: *váll*, shoulder, *vállal* (shoulders), undertakes, *vállalat*, enterprise; but *becs*, worth, *becsül*, (he) respects, *becsület*, respect. Whatever changes the Magyar language may have undergone under adverse circumstances, amid hostile nations, it has yet retained its essential peculiarities of phonetism, grammar, and construction. Although it contains many Slavic, Latin, German, Greek, and other foreign words, it has digested them in its own way, assimilating them otherwise than the western nations have done with the same element; thus, *schola*, Slav. *klas*, Ger. *Schnur*, became *iskola*, *kalász*, *sinór*. The concurrence of harsh sounds and of consonants is as much avoided as in all the languages of central and eastern Asia. The roots remain unaltered, and most frequently bear the accent in all their derivatives.—The most peculiar feature of Hungarian grammar is its system of suffixes. In the possessive forms of nouns they are varied according to the number and person of the possessor and the number of the object, giving 12 distinct terminations, as follows: *házam*, my house, *házaim*, my houses; *házad*, thy house, *házaid*, thy houses; *háza*, his or her house, *házai*, his or her houses; *házunk*, our house, *házaink*, our houses; *házatok*, your house, *házaitok*, your houses; *házok*, their house, *házaik*, their houses. In verbs they are made to indicate not only the voice, mood, and tense, and the person and number of the nominative, but the definiteness or indefiniteness of the object, and in one form (indicative present, first person singular) the person of the object, as *várlak*, I expect thee; *kérlek*, I ask thee. The following table exhibits the suffixes of the indicative present, the root being always the third person singular of the indefinite form, and the vowels varying, as above stated, in consonance with that of the root:

PERSON.	ACTIVE.				PASSIVE.	
	DEFINITE.		INDEFINITE.			
Plur. Sing.	1	-om, -em (-öm)	-ok, -ek (-ök)	-atom, -etem	-etel	
	2	-od, -ed (-öd)	-sz (Root)	-atol, -etel	-etik	
3	1	-ja, -i		-atik, -etük	-etük	
	2	-juk, -jök	-ünk, -ök	-atunk, -etünk	-etünk	
3	1	-játok, -jétek	-tok, -tek (-tök)	-attok, -ettek	-ettek	
	2	-ják, -ik	-nak, -nek	-atnak, -etnek	-etnek	

Examples: *várom*, I expect him, her, it, them, or the man; *várom*, I expect, wait; *váratom*, I am expected; *kéred*, thou askest him, &c.; *kérsz*, thou askest; *kéretel*, thou art asked; *látja*, he or she sees it; *lát*, he or she sees; *látjuk*, we see it; *látunk*, we see, &c. Other moods and tenses are formed by inserting new letters or syllables between the above suffixes and the root, or in a few cases by a change of the final vowel or consonant, and by auxiliaries; thus: *vára*, waited; *várnánk*, we waited; *vártunk*, we have waited; *várnánk*, we would wait; *várandok*, I shall wait; *várjatok*, that ye wait. The auxiliaries are: *volt* or *vála*, for the pluperfect; *legyen*, for the conjunctive past; *volna*, for the optative past. The infinitive is formed by suffixing *ni* to the root, as *várni*, to expect. A combined future is formed by the infinitive with the auxiliary verb *fog*; thus, *várni fogok*, I shall wait; *várni fogom*, I shall expect it. Possession is indicated by the irregular verb *lenni*, to be; *van*, is; *vannak*, are; *volt*, was; *lesz*, will be, &c.; thus: *anyám van* (mother-my is), I have a mother; also with the mark of the dative, *nekem vannak kerteim* (to-me are gardens-my, *mihí sunt hortí*), I have gardens. Negation is expressed by *nem*, not; *nincs*, is not, *nincsenek*, are not; *sincs*, is neither. Various kinds of verbs are made by affixing certain syllables, thus: *at* or *tat*, causative; *gal*, *gat*, &c., frequentative; *dúl*, incipitive; inserting *n*, diminutive; *hat*, potential; *ít*, *int*, &c., transitive; *közök*, reciprocal; *odik*, *kozók*, reflexive, &c. Examples: *ver*, he beats; *veret*, he causes to beat; *verget* (*verdes*, *verdegél*), he beats often; *verint*, beats softly; *verekedik*, fights with; *verődik*, beats against; *vergődik*, beats himself (breaks) through; *verhet*, can beat; *verethet*, can cause to beat; *verinhet*, can beat gently; *verekedhetik*, can fight with somebody; *verődhetik*, can knock against; *vergődhetik*, can break through, &c. All these and similar derivatives can be conjugated throughout in the same way as the simple verb. There are besides these other compounds with prefixes: *alá*, down; *átal*, through, by; *be*, in; *bele*, into; *el*, of, away; *ellen*, against; *fél*, up; *ki*, out; *össze*, together, &c.; and especially *meg*, which is an emphatic particle denoting attainment of the aim, accomplishment (like the German *er* and *be* in *erlangen*, *begraben*).—There is no gender; he and she are expressed by the same word. The definite article *az* or *a* is of recent use. The adjective precedes the substantive, and receives the marks of relations only when standing by itself. The relations called cases and those

expressed by prepositions in Indo-European languages are denoted in all Altaic tongues by suffixes. The plural is formed by *k*. Cases: *é*, genitive; *nak*, genitive and dative; *i*, *at*, accusative; *ban*, in; *ba*, into; *ból*, out of; *ért*, for; *hoz*, to; *ig*, till; *ként*, like, instead, as; *kép*, in manner of; *kor*, at the time of (about); *nál* (Latin *apud*, German *bei*), at; *on*, upon; *ról*, down; *ül*, instead, as; *vá*, (changed) into; *val*, with, by, &c.; almost all the suffixes being harmonized with the stem. Examples: *szemeinkben*, eyes-our-in; *ebédeikkor*, dinners-their-at-the-time-of. The separable postpositions are of three categories: 1, answering to three questions, where? whither? whence? thus: *előtt*, before (where?); *elő*, before (whither?); *elől*, from before; such are *alatt*, below; *körött*, around; *között*, between, among; *megett*, behind; *mellett*, near by; 2, of two forms, as *hegyett*, *hegyé*, upon, &c.; 3, of one form, as *ellen*, against; *íránt*, regarding, &c. The comparative degree is formed by suffixing *bő*; the superlative by prefixing *leg* to the comparative; thus: *nagy*, great, *nagyobb*, greater, *legnagyobb*, greatest. Pronouns: 1st person, *én*, I; *enyém*, mine; *nekem*, to me; *engemet*, me; *mí*, we; *miénk*, ours; *nekünk*, to us; *minket*, us; 2d person, *te*, *tiéd*, *neked*, *tégedet*; *ti*, *tiétek*, *nektek*, *titeket*; 3d person, of both genders, *ő*, *övé*, *neki*, *öt*; *ők*, *övék*, *nekik*, *öket*. These are joined with relative prefixes, thus: *bennem*, in me; *belőled*, out of thee; *hozzájok*, to them; *alattam*, under me; *alattad*, under thee, &c. In addressing a person we say *ön* (self), plural *önök*, or *kegyed* (thy grace), plural *kegyetek*, for both genders; or *az úr*, sir (the lord or gentleman); *uraságod*, sirship-thy; *az asszony*, lady; *asszonyságod*, ladyship-thy; formerly *maga*, self; to persons of lower standing, *kend*, you. Numerals: *egy*, 1; *kettő*, *két*, 2; *három*, 3; *négy*, 4; *öt*, 5; *hat*, 6; *hét*, 7; *nyolcz*, 8; *kilencz*, 9; *tíz*, 10; *tizenegy*, 11, &c.; *húsz*, 20; *harmincz*, 30; *negyven*, 40, &c.; *száz*, 100; *ezer*, 1,000. Ordinals: *első*, 1st; *második*, 2d; the others are formed by suffixing *dik*, as *negyedik*, *századik*, &c. All other varieties are formed by suitable suffixes. The formation of parts of speech, and of various categories of signification, is extremely luxuriant by means of suffixed letters or syllables, so that an indefinite and yet ever intelligible mass of words may be made to suit all conceptions and shades of meaning. This plasticity of the Magyar, together with its free syntax, renders it capable of expressing the turns of other tongues and the Greek and Latin metres with more ease and fidelity than almost any other language. We subjoin an example of construction and of elegiac distichs:

Férfiak! így szólott Pannon vész-istensé hajdan:
Men! so spake Pannonia's war-god (its) of old:

Boldog földet adok, víjátok érte ha kell,
Blessed country give-I, fight-ye for-it if need,

'S vittanak elsántan nagy bátor nemzetek érte
and fought decidedly great brave nations for-it

'S véresen a diadalt, végre kinyerte magyar.
and bloodily the victory lastly gained (the) Hungarian.

*Ah de viszály maradt a' népek' lelkein: a' föld
Alas, but discord remained the nations' souls-in: the land*
Boldogág nem tud lenni az itok alatt
happy-made not knows (can) be. the curse under.
(Vörösmarty.)

This language is spoken by more than one third of the population of Hungary in its wider sense, by more than one fourth of that of Transylvania, and in some places of Moldavia, Wallachia, and Bukowina. It consists of four dialects, which do not differ so much as those of other tongues, viz.: the Györi, of Raab, or Trans-Danubian, and the Bihari on the Theiss, both represented in books; the Palócz in the Mátra mountains, in the contiguous districts of the counties of Heves, Borsod, Gömör, Hont, and Nógrád, with more genuine ancient Magyar words than the preceding; and the Székely in Transylvania and the contiguous countries, with many Tartaric words, and of a drawing pronunciation. The language has varied very little in progress of time.—HUNGARIAN LITERATURE is comparatively of late date. The introduction of the religion of Rome under King Stephen I. (997-1038) made the Latin, the language of its priests and teachers, predominant in the court, the higher institutions for education, administration, and justice, and among the higher classes in general, who found it the most convenient medium for communication with the representatives of the cultivated West and South in diplomacy, literature, or religion. Of the time of the Árpáds and the next following period only Latin chronicles are preserved, of which those of the "Anonymous Secretary of King Béla" (II.) and Simon Kéza, the *Chronicon Budense*, and the *Chronicon Rerum Hungaricarum* of John Turóczy (Thurocius), are the most remarkable. The court of Matthias Corvinus (1458-'90) at Buda was adorned by distinguished native and foreign scholars. Of the latter, Bonfinus wrote an interesting though often legendary history of Hungary in *Decades IV.*, which was published with a continuation by Sambucus (Basel, 1568). Galeotus wrote on Matthias himself, whose librarian he was, and Callimachus on Attila and Uladislas I. Among the natives the poet Janus Pannonius holds the foremost rank. The preserved remnants of Hungarian writings of that period are very scanty. The spread of the reformation in the following century, as in most countries of Europe, promoted the culture of the native tongue. But the simultaneous disasters of the country, the Turkish and civil wars, and chiefly the introduction of the German element with the dynasty of the Hapsburgs, checked the development of a flourishing national literature. Parts of the Scriptures were translated into Hungarian during the 16th century by Komjáti, Erdösi, Heltai, Székely, Juhász, Károlyi, and others. Gál, Juhász, Kulcsár, Telegdi, Décsi, and Károlyi distinguished themselves as orators. Tinódi, Valkai, and Temesvári sang the

warlike exploits of their times in light verses, Kákonyi the deeds of Cyrus, Csáktornyi the heroes of the siege of Troy; Balassa, Rimai, and Erdösi composed lyrical poems of incomparably higher merit. In the 17th century the Hungarian muse found votaries in Zrinyi, the grandson of the defender of Sziget, who celebrated in rhymed alexandrines the deeds and death of that hero, in Liszti, Paskó, and Koháry, and especially in Gyöngyösi, who sang the defence of Murány by Maria Szécsi. Molnár and Káldi translated the Scriptures; the primate and cardinal Pázmán and Kecskeméti were distinguished as orators; Csere even published a cyclopædia of sciences and a treatise on logic in Hungarian. This national movement in literature was paralyzed by the growing influence of the German dynasty; the bloody persecutions of the patriots under Leopold I. (1657-1705) suppressed it almost entirely. The Latin again became predominant, being cultivated in the 18th century by a large number of scholars in every branch, who vied with each other in the purity of their dead idiom, and compared with whom the Magyar writers Faludi and Bessenyei, the founders of a classical and a French school in poetry, Orczy, Count Teleky, Baróczy, Révay, and others, formed but a feeble minority. A new and fertile period began about the close of the last century, chiefly in consequence of the Germanizing measures of Joseph II. (1780-'90), which caused a lively and general reaction. Societies for the cultivation of the national tongue were formed, literary, political, and scientific periodicals started, national theatres established, and various linguistic theories developed. This movement, being identical with the general regeneration of the nation, triumphed over all foreign elements after the first quarter of the present century, about the beginning of which Francis Kazinczy, the great reformer of the language after Révay, and the popular poet Csokonai, appear as the foremost in literature. The poets Dayka, Verseghy, and Virág, and the novelist Dugonics, were their contemporaries. The lyrical "Loves of Himfy" (*Hymfy szerelmei*), by Alexander Kisfaludy (1801), were received with general admiration, and were followed by his "Tales" (*Regék*) and other poems. Berzsenyi wrote glowing odes in Roman metre. The poets Andrew Horváth, Döbrentei, Vitkovics, Kis, and Paul Szemere, belong both to the period of regeneration and to the golden age of Hungarian literature, which embraces the 30 years preceding the revolution of 1848-'9. This period opens with the simultaneous activity of five classical writers, Charles Kisfaludy, the brother of Alexander, Kölcsey, Fáy, Czuczor, and Vörösmarty, of whom only the last three survived it. Kisfaludy may be regarded as the creator of the Hungarian drama by his tragedies, and still more by his really national comedies, some of which are as yet unsurpassed. Kölcsey's lyrical poems, ballads, and prose writings, inclu-

ding orations, are distinguished by a spirit of ardent patriotism. Fáy's "Fables" (*Mesék*) are excellent specimens of that kind of poetry, in the manner of Lessing. Czuczor, distinguished also as a grammarian and lexicographer, is chiefly renowned for his popular songs and his historical epics in hexameter, the "Battle of Augsburg" (*Augsburgi ütközet*) and "Assembly of Arad" (*Aradi gyűlés*). The latter, however, were excelled by the more numerous epics of Vörösmarty, "Cserhalom," "The Flight of Zalán" (*Zalán futása*), "Erlau" (*Eger*), &c., which, together with his tragedies, short novels, songs, and especially odes and ballads, gave him the foremost rank among the writers of his nation. In lyrical poetry, next to Vörösmarty and Kőlcsey we find Bajza, who is also remarkable as an æsthetic critic and historical writer, Peter Vajda, John Erdélyi, Kunoss, Alexander Vachott, Császár, and Garay, whose ballads also rival those of Vörösmarty. Toward the close of the period appear the three youthful popular poets Tompa, Arany, and Petöfi, of whom the first two excelled chiefly in tales and legends, and the last in light and playful songs, whose subjects are love, liberty, independence, nature, and all that can touch the heart or inspire the imagination. Fictitious literature was chiefly cultivated, if not created, by Jósika, whose historical novels, "Abafi," "The Last of the Báthoris" (*Utolsó Báthory*), "The Bohemians in Hungary" (*Csehek Magyarországon*), &c., exercised the greatest influence upon the development of Hungarian prose after Kazinczy. Smaller though not inferior works were written by Peter Vajda. In many respects both were surpassed by Eötvös, whose "Carthusian" (*A carthususi*), a philosophical romance, "Village Notary" (*A falu jegyzője*), an admirable picture of recent political life in Hungary, and "Hungary in 1514" (*Magyarország 1514-ben*), a historical novel, place him among the most eminent writers of his age. Kuthy is often eminent in pictures of nature, and Ignatius Nagy in caricaturing characters; both produced imitations of Sue's "Mysteries," taken from Hungarian life, but disfigured by unnatural exaggerations. Kemény and Jókai belong also to a more recent period, both as novelists and publicists. The principal dramatic authors besides Kisfaludy and Vörösmarty were Katona (*Bankbán*), L. Tóth, Garay, Szigligeti, who is eminent in popular plays, Gál ("The Notary of Peleske"), I. Nagy, Emeric Vahot, Paul Kovács, and Czakó. Travels were written by Belenyei (America), Császár (Italy), Bartholomew Szemere, Irinyi, L. Tóth, and Gorove (western Europe), Méhes (Switzerland), Jerney (southeastern Europe), and Reguly (northern Russia), the work of Szemere being one of the most remarkable productions of the period; political works by Szechenyi, Wesselényi, Kosuth, Eötvös, Szalay, B. Szemere, and others; the best histories by M. Horváth, Péczely, and Jászay (Hungary), Bajza (the ancient world),

and Toldy (national literature); philosophical treatises by Szontágh, Márki, Gregus, and others; the best statistical works by Fényes, Vállas, and Köváry. Natural sciences, theology, languages, and antiquities also found numerous representatives. The best grammatical and lexicographical works on the national language were written by Czuczor, Fogarassy, and Bloch. The beautiful songs of the people were published in various collections, among others by Erdélyi; miscellaneous writings by Pulszky, Lukács, Frankenburg, Gabriel Kazinczy, Gondol, Berecz, Pompéry, Amelia Bezerédy, Theresa Karacs, and others. Of translators we will mention only Szabó, who published an admirable metrical version of Homer. During the revolution of 1848-'9 the muses were silent, excepting only the stirring songs of war. The battle field closed many a glorious career, as in the case of Petöfi, and destroyed many an incipient genius, as in that of the eloquent Vasvári. After the close of the war the dungeon, the scaffold, and exile doomed the most gifted of the nation to silence. The last quarter of a century is therefore in a literary respect inferior to the preceding period, though productive of a large number of publications of different degrees of merit. Some of them, mostly belonging to the surviving representatives of the preceding period, are worthy of their great popularity. In poetry the imitators of Petöfi have been numerous. Among the most remarkable productions are the poems of Tompa, Arany, Sárossy, Lisznyai, Lévai, Gyulai, Nicholas Szemere, Szász, Jámor (Hiador), Sükei, Szelestei, Bozzai, Losonczy, Székely, and others; the novels of Kemény, Jósika, Jókai, Pálffy, Gyulai, and Béreczy; the humorous writings of Bernát and Radakovics (Vas Gereben); the historical works of Szalay, Joseph Teleky, Jászay, Toldy, Csengery, Palugyai, Mészáros, Fejér, J. Hunfalvy, &c.; the political writings of Eötvös and Kemény; the translations of Stephen and Charles Szabó, P. Hunfalvy, Csengery, Irinyi, Szász, and Sükei; the travels of Emanuel Andrásy (India), Nendtwich (America), Podmaniczky (northern Europe), Magyar (southern Africa), Emma Teleky (Greece), &c.; and the dramas of Szigligeti and others. Journalism and oratory, both of which attained their highest development during the later period of Kossuth's agitation, have been revived by the restoration of the Hungarian constitution. This sketch, which includes various Magyar productions of the Transylvanian press, excludes all more modern non-Magyar literary productions of Hungary belonging to the Slavic, German, or other literatures.—Among the principal works on Hungarian history (in various languages) are those of Bel, Pray, Gebhardi, Katona, Fessler, Engel, Majláth, Horváth, Péczely, Toldy, A. de Gérando, Szalay, and Kerékgyártó. See also A. J. Patterson, "The Magyars: their Country and Institutions" (2 vols., London, 1869).

HUNGARY, Wines of. In respect to climate and soil Hungary may be considered a country unusually well adapted to the culture of the grape; but although wine is produced in almost every portion of it, only a comparatively small amount is available for the purposes of commerce. The total production may be estimated at nearly 400,000,000 gallons, not more than 50,000,000 of which are capable of being rendered fit for export. The amount annually leaving the country is in fact very much less than this, owing to the imperfect system of viticulture practised by the producers, and to defective and primitive treatment of wine in the cellar. The wines are of three kinds: *samorodny* or "natural wine;" *máslás*, which is made of dry and plump grape berries, used in certain proportions; and ordinary wine, made from plump grapes only. It is a peculiarity of the Hungarian vines that the grapes ripening earliest often burst and discharge a portion of their juice, after which they dry up and are converted into lumps of sugar, called *aszu* (Ger. *Trockenbeeren*) or dry berries. These very rarely comprise an entire bunch, but are interspersed with fully ripe and plump grapes. It is customary at the vintage to separate the dry berries from the others; but when the clusters are put into the press without undergoing this process, the product is known as natural wine. The choice varieties are made from the ordinary wine, with the addition of dry berries. This is *máslás*. It is of four qualities, according to the quantity of dry berries added to each cask of wine. When reinforced beyond these proportions, it is called *aszubor* or *Ausbruch*, the choicest kind of which is that running spontaneously from the musk-infused dry berries, known as "essence." These fortified wines are, as a rule very alcoholic and sweet, and are the chief wines of commerce. The most famous product of the Hungarian vines is the Tokay wine, which is made in the vineyards covering the slopes of the Hegyalja range of hills, near the town of Tokay, in northern Hungary. Five qualities are classified: Essence, *ausbruch*, *máslás*, *samorodny*, and ordinary. Of these the first is probably the most costly wine in the world, selling, when 50 years old and upward, at from \$5 to \$15 the small Tokay bottle. Dr. Druitt in his "Report on Cheap Wines," commending the use of Tokay by invalids, describes the essence as "a wine of delicate pale tint, in which the sweetness and fragrance of the grape, though perceptible, are partly hidden by, or converted by age into, an exceedingly rich, aromatic, mouth-filling wine flavor, so that, rich as it may be, it is not cloying nor sickly; and in its admirable aroma there is a decided remembrance of green tea." This has long been considered peculiarly the wine of crowned heads and princes, and is rarely if ever for sale. The *ausbruch* and other qualities of Tokay also command high prices, and are usually found in limited quantities wherever costly wines are in the market.

Among other Hungarian wines of the first class, but ranking below the Tokays, may be enumerated the *Ménes Magyarat*, red and white *ausbruch*, and natural wines, yielding about 3,000,000 gallons, and the wines of Rust, produced in the country lying west of the river Raab, and yielding annually between 800,000 and 900,000 gallons of white, strong, sweet *ausbruch* and natural wine. Wines of the second class comprise those of Somlyó, Badacsony, Neszemély, Érmellék, Szerednye, Nógrád, and Krassó, which are white; and Erlau, Visonta (called also Schiller), Szegszárd, Villány, Buda (Ofner), and Krassó, red wines. Those of the third and fourth class are scarcely known beyond the confines of the region in which they are produced. Hungarian wines, though comparatively new at the present time to Great Britain and the United States, were introduced into the former country as early as the reign of James I., and, on the authority of a German author of the last century, Helvetius, "were the favorite wines of the court and all over the kingdom." They were subsequently supplanted by port, sherry, and madeira. Friedrich Hoffmann, professor of medicine at Halle, and a man of great mark in his profession, declared in 1685, in an essay "On the Excellent Nature, Virtue, and Use of Hungarian Wines," by which he means the sweeter wines of the Tokay order, that they excel all other wines, in that they are strong, preserve their sweetness, have spirit, odor, and aroma; are strengthening, and yet open the pores of the skin and other organs, so that they cause no headache nor languor; and that the better wines keep for an unlimited time.—In connection with the wines of Hungary may be considered those of Austria, in many parts of which country the vine is largely cultivated. The average yield may be estimated at between 200,000,000 and 300,000,000 gallons, including many wines of fair quality and good keeping properties. Most of this is consumed within the country. The finest varieties are those of Vöslau, Goldeck, and Steinberg, of each of which there is a red and a white kind. The vines employed are those of Portugal, and their products are said to bear some resemblance both to port and burgundy. They resemble Madeira wines also in returning greatly improved from a sea voyage of several years. The sparkling Vöslauer, an effervescent wine, has considerable flavor and a delicate aroma. The vineyards producing these wines lie S. of Vienna, between the Hungarian hills and the Styrian Alps, and enjoy a climate well adapted to the maturing of delicately flavored wines. Dr. Druitt sums up his opinion of them as follows: "The richness of the overripe white grapes destined to produce the cabinet wine; the amplitude of the cellars excavated in the bowels of a hill; the vicinity of sulphur springs and volcanic débris; and the immense care, activity, and conscientiousness employed, bespeak a great future for these wines."

HUNGER, the sensation by which the necessity for food is made known to the system, referred to the stomach, but indicating the wants of the system at large; impelling us to supply the waste of the tissues consequent on all vital acts, and in proportion to the activity of the animal functions from exercise, &c. If the desire cannot be gratified, or if absent from disease, the phenomena of inanition or of starvation are induced, with a diminution of the bulk of nearly all the tissues and proportionate weakness. Hunger is greatest in the young and growing state, and least in old age, when the vital operations are deficient in activity. It varies with the amount of heat to be generated in the body; external cold increases hunger, while heat diminishes it; hence the voracious appetite of the arctic regions, and the general use of stimulating condiments in the tropics; it is also increased by any unusual drain upon the system, when accompanied by febrile action, as in lactation and diabetes, in the last of which especially hunger is almost insatiable. In health, the feeling of hunger is a very good indication of the demands of the system for food, and it becomes the stimulant to mental operations, automatic in infancy, but directed by intelligence in the adult, which have for their object the gratification of the desire. Hunger depends rather upon the demand of the system for aliment than upon the state of emptiness of the stomach. The sense of hunger may be, however, immediately dependent on some condition of the stomach; it is well known that the swallowing of indigestible and non-nutritious substances will temporarily relieve it. The demands of the stomach and of the general system in this respect are probably communicated to the sensorium by the pneumogastric nerves and by the sympathetic. On the other hand, mere emptiness of the stomach does not produce hunger, as is evident from the fact that an ample supply of food passes entirely from the stomach hours before this sensation is felt, and that in disease there may be no desire for food for many days with total abstinence from it. Moreover, hunger may be relieved by the injection of alimentary fluids into the large intestine, when the stomach cannot receive or retain food.

HUNS (Lat. *Hunni*), a people of northern Asia who in the 5th century invaded and conquered a great part of Europe. Of their origin little is known with certainty. Under the name of Chuni they were known to the Greeks, and are mentioned by Ptolemy as early as the 2d century. According to the theory of De Guignes in his *Histoire des Huns*, the Huns were a Tartar nation, the Hiung-nu, whose original country was the region immediately north of the great wall of China, which was built to protect that empire against their incursions. For several ages they carried on successful wars against the Chinese emperors, who were compelled to pay them tribute in order to purchase a precarious peace. Their

power was at length broken by the arms of the emperor Vouli and by their own dissensions, and in the first century of the Christian era the unconquered remnant of the nation abandoned their country and marched westward in search of a new home. One division established themselves on the E. side of the Caspian sea, where they became known as White Huns. The main body of the nation established themselves for a while in Russia on the banks of the Volga. In the 3d century they crossed this river and invaded the territory of the Alans, whom they conquered and amalgamated with themselves. The united nations pressed onward, and attacked the Goths in 375. The Goths were defeated, their king Ermanric put to death, and the Gothic nation driven to seek an asylum within the bounds of the Roman empire. The Huns established themselves on the banks of the Don and the Dnieper and in Pannonia. They soon became involved in war with the Romans, and in the 5th century under the leadership of Attila attained to a high degree of power and empire. (See *ATTLA*.) Their dominion fell to pieces after the death of Attila (about 453), and the people themselves were lost and swallowed up in fresh invasions of barbarians from the north and east. The Huns of the Byzantine authors included many distinct tribes which invaded Europe in successive waves, including the Avars. Howorth identifies the Hunnic Avars with the Iouan-Iouan, who appear in Chinese history in the beginning of the 3d century A. D. Some time later they are found on the Jaxartes, and invading Transoxiana, where they intermarried with the Yethas or Ephtalitæ. They compelled these latter to emigrate to the south of the Oxus, and during the 4th and 5th centuries extended their power as far as India. The whole frontier of eastern Persia is then described by western writers as infested by enemies, to whom the name of White Huns is given. Cosmas Indicopleustes, who was in India about 525, gives the name of Hunnia to the vast territory separating India from China. Thus, while Europe and the west were flooded by one wave of Huns, eastern Persia and the Indian border were flooded by another. Howorth has also attempted to prove that the Khazars or Akatzirs were the same race as the Ephtalitæ of the Persian frontier. According to some writers, the Huns were a tribe of Finnish stock, and the ancestors of the Hungarians or Magyars. They are described by the Roman writers as hideous in appearance, with broad shoulders, flat noses, and small black eyes, deeply buried in the head. "A fabulous origin was assigned to them," says Gibbon, "worthy of their form and manners; that the witches of Scythia, who for their foul and deadly practices had been driven from society, had copulated in the desert with infernal spirits; and that the Huns were the offspring of this execrable conjunction. The tale was greedily embraced by the credulous terror of

the Goths; but, while it gratified their hatred, it increased their fear, since the posterity of demons and witches might be supposed to inherit some share of the preternatural powers as well as of the malignant temper of their parents."—See *Histoire générale des Huns, Turcs, Mogols et autres Tartares occidentaux*, by Joseph de Guignes (5 vols. 4to, Paris, 1756-'8); and *Histoire d'Attila et de ses successeurs*, by A. Thierry (3d ed., Paris, 1865).

HUNT, a N. E. county of Texas, drained by the head streams of the Sabine river and by the S. fork of the Sulphur; area, 935 sq. m.; pop. in 1870, 10,291, of whom 1,078 were colored. It has a rolling and in some places hilly surface, and is well wooded. The soil is fertile. The chief productions in 1870 were 342,411 bushels of Indian corn, 31,480 of sweet potatoes, 163,267 lbs. of butter, and 4,272 bales of cotton. There were 9,941 horses, 977 mules and asses, 9,672 milch cows, 2,077 working oxen, 25,141 other cattle, 7,194 sheep, and 23,347 swine; 1 flour mill, and 1 wool-carding establishment. Capital, Greenville.

HUNT, Henry, an English politician, born at Upavon, Wiltshire, Nov. 6, 1773, died at Alresford, Hants, Feb. 13, 1835. He was a wealthy farmer, and in early life was noted for extreme loyalty, having in 1801, during the alarm at the projected French invasion, offered to place his personal property, valued at £20,000, at the disposal of government. He subsequently retired in disgust from the Everly troop of yeomanry on account of their refusal to volunteer their services out of the county, and joined the Marlborough troop. Having challenged his commander, Lord Bruce, he was tried and sentenced to pay a fine of £100, and to be imprisoned for six weeks in the king's bench. During his confinement he was visited by several prominent reformers, under whose influence he became a champion of the most radical section of the party, and the political associate of Sir Francis Burdett, Horne Tooke, and William Cobbett. For many years he attempted without success to secure a seat in parliament, addressing popular meetings in the large manufacturing towns and in other parts of the kingdom. In August, 1819, he presided over the reform meeting in Manchester, which for alleged illegality was dispersed by the military, after 11 persons had been killed and upward of 600 wounded; and an indictment for conspiracy was found against him. He was sentenced to 2½ years' confinement in Ilchester jail, and after his release made a public entry into London on Nov. 4, 1822. In 1830 and 1831 he was returned to the house of commons from Preston; but failing of an election to the next parliament, he made the tour of England in a handsome equipage, speaking in the principal towns, and offering for sale, under the name of "radical coffee," roasted grains of wheat, as a substitute for the heavily taxed coffee of the West and East Indies. Subsequently he made his ap-

pearance in London in a coach drawn by white horses, from which he sold a new kind of blacking invented by himself. He died of a stroke of paralysis while on a tour.

HUNT. I. James Henry Leigh, an English author, born in Southgate, Middlesex, Oct. 19, 1784, died at Putney, Aug. 28, 1859. His father, a West Indian, married an American lady, and practised law in Philadelphia till the revolution broke out, when he warmly espoused the cause of the crown and had to leave the country. He went to England, took orders, and became tutor to Mr. Leigh, nephew of the duke of Chandos, after whom he named his son. Leigh Hunt was educated at Christ's hospital, which he left in his 15th year, spent some time in the office of his brother, an attorney, and then obtained a place in the war office. He had written many verses while a boy, and in 1801 his father published for him "Juvenilia, or a Collection of Poems written between the Ages of Twelve and Sixteen." He now began to contribute to periodicals, and in 1805 became the dramatic critic of the "News," a Sunday paper established by his brother John, to which also he contributed literary articles. A volume of his theatrical criticisms was published in 1807. In 1808 he left the war office, and with his brother established the "Examiner," a liberal journal, which he edited for many years and rendered exceedingly popular; it was noted for the fearlessness of its criticism and the freedom of its political discussions. Three times the Hunts were prosecuted by the government: first, for the words, "Of all monarchs, indeed, since the revolution, the successor of George III. will have the finest opportunity of becoming nobly popular;" second, for denouncing flogging in the army; third, when a fashionable newspaper had called the prince regent an Adonis, for adding "a fat Adonis of fifty." On the first the prosecution was abandoned, on the second the verdict was for acquittal, but on the third the brothers were sentenced to a fine of £500 each, and two years' imprisonment. They rejected offers to remit the penalties on condition that the paper should change its tone, and underwent the full sentence; but so much popular sympathy was excited in their behalf that the cells were transformed into comfortable apartments, constantly supplied with books and flowers. Here Leigh was visited by Byron, Moore, Lamb, Shelley, and Keats, and here he wrote "The Feast of the Poets" (1814), "The Descent of Liberty, a Mask" (1815), and "The Story of Rimini" (1816), which immediately gave him a place among the poets. He also continued to edit the "Examiner" while in prison. In 1818 he published "Foliage, or Poems original and translated," and in 1819 he started the "Indicator," a small weekly on the model of the "Spectator." A selection of his best essays from this was published under the title of "The Indicator and Companion" (2 vols.

8vo, 1822). But his pecuniary affairs had become badly involved, and in June, 1822, on the invitation of Byron and Shelley, he went to Pisa, Italy, to assist them in editing the "Liberal," a journal intended to be ultra-liberal in both literature and politics. Shelley's death occurred in July, and Hunt resided with Byron for several months; but the journal proving a failure and the association uncongenial, the poets separated with decidedly unpleasant impressions of each other. Hunt remained in Italy for some years, and after his return to England published "Recollections of Lord Byron and some of his Contemporaries" (4to and 2 vols. 8vo, 1828). In this book the character of Byron was set forth in so unfavorable a light that his friends, especially Moore, retorted upon its author in the severest manner. Years afterward Hunt confessed that he was ashamed of it. From this time his life was constantly devoted to the production of books. He had always been sneered at as a cockney by certain critics, and was frequently in great pecuniary straits, until in 1847 he received a literary pension of £200, but plodded on with unceasing industry. He translated Tasso's *Aminta*, Redi's *Bacco in Toscana*, Boileau's *Lutrin*, and numerous other works; edited the plays of Wycherly, Congreve, Vanbrugh, Farquhar, and Sheridan, and an expurgated edition of Beaumont and Fletcher; and was a frequent contributor to the literary and political columns of newspapers and magazines. Among his other works are the following: "Sir Ralph Esher," a novel (1832; new ed., 1850); "Captain Sword and Captain Pen," a metrical satire against war (1835); "The Legend of Florence," a drama (1840); "The Seer," a collection of essays (1841); "The Palfrey," a love story in rhyme (1842); "Stories from the Italian Poets, with Lives of the Writers" (2 vols., 1846); "Men, Women, and Books" (2 vols., 1847); "The Town" (2 vols., 1848); "Autobiography" (1850); "Table Talk, with Imaginary Conversations of Pope and Swift" (1851); "Religion of the Heart" (1853); and "The Old Court Suburb" (1855). Shortly before his death he collected and arranged a complete final edition of his poems. A selection from his correspondence was published in 1862. **II. Thornton**, an English author and art critic, son of the preceding, born in London, Sept. 10, 1810, died June 24, 1873. He studied the art of painting, but soon abandoned it for journalism, conducted the political department of the "Constitutional" until that journal ceased to exist, edited successively the "North Cheshire Reformer" and the "Glasgow Argus," and from 1840 to 1860 was connected with the London "Spectator." He published "The Foster Brother," a romance (1845), and edited his father's "Autobiography" (1850) and "Correspondence" (1862).

HUNT, Richard Morris, an American architect, born in Brattleboro, Vt., Oct. 28, 1828. In 1843 he went to Europe, where he studied his

profession at the school of fine arts in Paris, and under Hector Lefuel, and made a tour through various parts of Europe, Greece, Asia Minor, and Egypt. Returning to Paris, he was engaged as inspector under Lefuel, then architect to the emperor, on the new building connecting the Louvre and the Tuilleries. On his return to America in 1855, he was employed upon the capitol extension at Washington. Since then he has executed many public and private works, of which the most important are the Presbyterian hospital, the Stevens apartment house, the Lenox library, and the Tribune building in New York; the Yale divinity college in New Haven; the Stuyvesant building, New York; the Brimmer houses, Boston; the residence of J. Q. A. Ward, New York; and several villas at Newport, R. I.

HUNT, Thomas Sterry, an American chemist, mineralogist, and geologist, born in Norwich, Conn., Sept. 5, 1826. He studied medicine for a time, but, devoting himself to chemistry, became in 1845 a private student with Prof. B. Silliman, jr., of New Haven, acting meanwhile as chemical assistant to Prof. Silliman, sr., in the laboratory of Yale college. After two years thus spent he was in 1847 made chemist and mineralogist to the geological survey of Canada, then just begun under the direction of Sir William Logan. He held this post for more than 25 years, but resigned it in 1872, and accepted the chair of geology in the Massachusetts institute of technology, where he succeeded Prof. William B. Rogers. His earlier studies were directed especially to theoretical chemistry, then assuming shape from the labors of Liebig, Dumas, Laurent, and Gerhardt. It was as the reviewer, interpreter, and critic of these chemists that Mr. Hunt first became known, while he at the same time developed from some germs in the writings of Laurent a new system essentially his own, in which all chemical compounds are deduced from simple types represented by one or more molecules of water or of hydrogen. These views, maintained by him in a series of papers in the "American Journal of Science," beginning in 1848, have at length been universally adopted, and are now recognized as one of the foundations of modern chemical theory. His philosophy of the sciences has been influenced by the study of Kant, and still more of Hegel and Stallo, as may be seen in his essays on "Solution," "Chemical Changes," and "Atomic Volumes," which first appeared in the "Journal" (1853-4), and were republished in England and Germany. In these he attacks the atomic hypothesis and all its consequences, and asserts that solution is chemical union, and chemical union identification. His researches on the equivalent volumes of liquids and solids were a remarkable anticipation of those of Dumas, while in his inquiries into the polymerism of mineral species he has opened a new field for mineralogy, as set forth later in his essay on the "Objects and Method of Mineralogy." His philosophical studies

have however been only incidental to his labors in chemical mineralogy and chemical geology. His researches into the chemical and mineral composition of rocks have probably been more extended than those of any other living chemist; and his investigations of the chemistry of mineral waters, which are not less so, have enabled him to frame a complete theory of their origin and formation, and their relations to the origin of rock masses both crystalline and uncrystalline, and to lay the basis of a rational system of chemical geology. From his long series of studies of the salts of lime and magnesia he was enabled to explain for the first time the true relations of gypsums and dolomites, and to explain their origin by direct deposition. His views on this subject are now, after many years, finding recognition among geologists. He has also carefully investigated petroleum both in its chemical and geological relations. The phenomena of volcanoes and igneous rocks have been discussed by him from a new point of view, and he has revived and enforced the almost forgotten hypothesis of Keferstein that the source of these is to be sought in chemical reactions set up in the sedimentary deposits of the earth's crust through the agency of internal heat. In this discussion he was the first to point out and explain the relation between modern volcanic phenomena and great accumulations of comparatively recent sedimentary formations, as well as the nature of the relations between these and folded and contorted strata. He has sought to harmonize the facts of dynamical geology with the notion of a solid globe, which he early adopted in opposition to the generally received one of a globe with a liquid interior, and has also developed a theory of cosmogony based upon the chemical and physical conditions of a world consolidating from a vaporous mass, and has endeavored to show how the earth, air, and ocean have assumed their present condition under the slow operation of natural causes. His views on these questions will be found in an essay on "The Chemistry of the Earth" in the report of the Smithsonian institution for 1869; while his conclusions on many points of geology are embodied in his address delivered as retiring president before the American association for the advancement of science at Indianapolis in 1871, on "The Geognosy of the Appalachians and the Origin of Crystalline Rocks," and in others of his recent papers, such as "Notes on Granitic Rocks," "The Geognostical Relations of the Metals," and "The History of the Names Cambrian and Silurian in Geology." Besides his papers in the "American Journal of Science," which number more than 100, and numerous articles communicated to the French academy and the scientific journals of France, England, and Canada, he has contributed largely to the reports of the geological survey of Canada, and to the work entitled "Geology of Canada" (1863), the

latter half of which is from his pen. He is also the author of a summary of organic chemistry forming a part of Prof. Silliman's "First Principles of Chemistry" (1852). A volume of his collected scientific essays is now in press (1874). He is also known for his researches, both theoretical and practical, into the chemistry and metallurgy of iron and of copper, some of which will be found in the "Proceedings of the American Institute of Mining Engineers." Dr. Sterry Hunt received in 1854 the honorary degree of A. M. from Harvard college, and later the degrees of LL. D. and Sc. D. from the universities of Montreal and Quebec, in both of which he was for many years a professor, and in the latter of which he lectured in the French language. He was a member of the international jury at the exhibitions of Paris in 1855 and 1867, and is a member of various academies and learned societies both in Europe and America. He was made a fellow of the royal society of London in 1859, and of the national academy of the United States in 1873. He is also an officer of the French order of the legion of honor.

HUNT, William Henry, an English water-color painter, born in London in 1790, died Feb. 10, 1864. He became a member of the old society of painters in water colors in 1824, and from that time regularly contributed to their annual exhibitions. As a colorist he ranked among the first painters of the day.

HUNT, William Holman, an English painter, born in London in 1827. He studied in the school of the royal academy, and in 1846 exhibited his first picture, entitled "Hark," which was followed by a scene from "Woodstock" (1847), the "Flight of Madeline and Porphyro," from Keats's "Eve of St. Agnes" (1848), and "Rienzi vowing to obtain Justice for the Murder of his Brother," from Bulwer's novel (1849). In 1850 appeared his "Converted British Family sheltering a Christian Missionary from the Persecution of the Druids," the first fruits of the new "pre-Raphaelite" movement in British art. He had in the previous year associated himself with John Everett Millais and Dante Gabriel Rossetti, for the purpose of restoring to the art the earnestness and conscientious accuracy that animated the painters who preceded Raphael. Mediævalism in theology and architecture was the prevailing mode of the day, and the young artists showed the influence which it had perhaps unconsciously exerted upon them, by styling themselves "pre-Raphaelites;" although they distinctly avowed their object to be chiefly the study of nature, to which they looked for inspiration, and the minutest details of which they proposed to copy with scrupulous accuracy. By common consent Hunt was regarded as the leader of the new school, which was shortly joined by Charles Collins and other young artists; and notwithstanding much hostile criticism and ridicule, he continued year by year to develop the idea with which he

started. In 1851 appeared his "Valentine rescuing Sylvia from Proteus," in 1852 "The Hireling Shepherd," and in 1853 "Claudio and Isabella" and "Our English Coasts," a pre-Raphaelite study of the downs at Hastings, all strongly imbued with the characteristics of the new style. In 1854 he produced two powerful pictures, "The Awakened Conscience" and "The Light of the World." The summer of 1855 was spent by Mr. Hunt on the shores of the Dead sea, where he took minute studies of the surrounding scenery, which were subsequently embodied in his picture of the "Scape Goat," exhibited in the succeeding year. To the universal exposition of 1867 in Paris he sent "After Sunset in Egypt." Mr. Hunt resided for some years in Jerusalem engaged in painting a picture recently finished, "The Shadow of Death," for which he received 10,000 guineas.

HUNT, William Morris, an American painter, born in Brattleboro, Vt., March 31, 1824. He entered Harvard college in 1840, but went to Europe on account of his health before the completion of his course, and in 1846 entered the academy at Düsseldorf, with the intention of studying sculpture. At the expiration of nine months he went to Paris, and in 1848 became a pupil of Couture. In 1855 he returned to the United States, and has since resided at Newport, R. I. His paintings comprise portraits, history, and *genre*, and among the most successful are several representing picturesque types of city life in Paris, of which the artist published a series of lithographs executed by himself in 1859. Among his later works are the "Morning Star," and the "Drummer Boy" and the "Bugle Call," illustrating incidents in the civil war.

HUNTER, John, a British surgeon and physiologist, born at Long Calderwood, Lanarkshire, July 14, 1728, died in London, Oct. 16, 1793. He was the son of a farmer, and the youngest of ten children. At 17 years he went to Glasgow to assist his brother-in-law, a cabinet maker; but soon returned home, and wrote to his brother William, who was already successful as a lecturer on surgery, offering to assist him in his anatomical labors. His brother's reply was favorable, and he went to London in September, 1748. He soon gave evidence of his abilities in the dissecting room. In 1749-'50 he attended the practice at Chelsea hospital, and in 1751 became a pupil at St. Bartholomew's hospital, continuing at the same time his labors in the dissecting room of his brother. In 1754 he became surgeon's pupil at St. George's hospital, of which he was appointed house surgeon two years later; and in the winter of 1755 he became a partner in the lectures of his brother. In the mean time he had succeeded in following more minutely than had before been done the ramifications of the olfactory nerve, in tracing the branches of the fifth pair of nerves, in discovering the system and functions of the lymphatic vessels in birds, and the cause and mode

of descent of the testis in the fœtus. In 1759 he obtained the appointment of staff surgeon in the army, accompanied the expedition to Belleisle in 1761, and after the siege of that place served in Portugal until the peace of 1763. During this time he collected the materials for his work on gun-shot wounds, which was published after his death. He returned to London, was put on half pay, and was obliged to receive pupils in anatomy and surgery as a means of subsistence. Purchasing a small piece of ground about two miles from London, he built a house, and carried on there his investigations in comparative anatomy. He bargained with the keepers of menageries for the bodies of dead animals, spent all his available means in procuring rare species, and often exposed himself to personal danger in watching their habits and instincts and experimenting on their dispositions. His papers communicated to the royal society drew attention to his labors, and in 1767 he was elected a fellow of the society, and the following year surgeon of St. George's hospital and a member of the college of surgeons. In 1771 he married the sister of Sir Everard Home, his pupil and subsequently his biographer, and in the same year published his first original work, "Natural History of the Human Teeth" (4to), of which the second part appeared in 1778. In 1773 he commenced his first regular course of lectures, a task which he seldom succeeded in discharging with satisfaction to himself or his pupils, and as a preparation for which he was accustomed to dose himself with laudanum. In 1776 he was appointed surgeon extraordinary to the king, and at the request of the royal humane society drew up a paper on the best mode of restoring apparently drowned persons. He also published papers on the action of the gastric juice upon the stomach after death, the torpedo, electric eel, &c. Between 1777 and 1785 appeared his papers on the heat of vegetables and animals, the structure of the placenta, the organs of hearing in fishes, &c., and the six Croonian lectures on muscular motion. The paper on the placenta, claiming for the author the discovery of the union between the uterus and placenta, which William Hunter had claimed in 1775 in his "Gravid Uterus," caused an estrangement between the brothers which only terminated a short time before the death of William. In 1785 he removed his whole museum to a house erected for the purpose in Leicester square, to which he admitted the public in May and October of each year. It had now assumed enormous dimensions, and such was his reputation as a naturalist that no new animal was brought to the country which was not shown to him. In the same year he was prostrated by a severe spasmodic attack, and was obliged to relinquish practice for a time; and thenceforth until his death he was a constant sufferer, his paroxysms occurring after any mental excitement. He nevertheless persevered in his ex-

periments, and was constantly performing operations then new to the art of surgery. Soon after his attack in 1785 he practised the new method of tying the artery for popliteal aneurism, which has been called the most brilliant surgical discovery of the century. In 1786 appeared his "Treatise on the Venereal Disease" (4to, London; new ed. by Sir Everard Home, 1809, and by Joseph Adams, 1818), and "Observations on Certain Parts of the Animal Economy" (4to, London; new ed. by Prof. Owen, 1800, 1837), the latter a republication of papers from the "Philosophical Transactions," and of others on anatomical and physiological discoveries by the author. In the same year he was appointed surgeon general of the army, and in 1787 he received the Copley gold medal from the royal society for papers on the ovarium, the specific identity of the wolf, jackal, and dog, and on the structure and economy of whales. Soon after he published valuable papers on the treatment of inflamed veins, on intusussception, and on the mode of conveying food into the stomach in cases of paralysis of the œsophagus; and in 1792 he contributed his last paper to the "Philosophical Transactions," entitled "Observations on the Economy of Bees." In this year he resigned his lectureship at St. George's hospital, and devoted himself to the completion of his work on inflammation. On Oct. 16, 1793, while attending a meeting of the board of directors of St. George's hospital, he became violently excited by a remark made to him by one of his colleagues, and leaving the room instantly expired.—As a surgical operator John Hunter was undoubtedly one of the greatest men of his time. As an anatomist and physiologist, he displayed a keenness of intellect, a faculty of generalization, and a philosophic turn of mind, which must rank him among the greatest of modern natural philosophers, and of which he has left an enduring monument in the celebrated museum named after him, and in 1799 purchased by the nation and placed in the keeping of the college of surgeons. At the time of his death it contained more than 10,000 preparations illustrating human and comparative anatomy, physiology, pathology, and natural history, so arranged as to exhibit the gradations of nature from the simplest form of life up to man. The physiological series, which comprised considerably more than half the collection, contained 1,000 skeletons, 3,000 animals and plants illustrating natural history (the animals stuffed or preserved in spirits), and 1,200 fossils, besides monsters and other eccentric forms of animal life. He left in addition 19 MS. volumes of materials for a catalogue of his museum, the preparation of which occupied him during the last few years of his life. The completion of the work was assigned to Sir Everard Home, his executor, who was intrusted for that purpose with the ten most valuable volumes, which he subsequently burned, in accordance, as he said, with

Hunter's express desire; although there is little doubt that he destroyed them to conceal his own appropriation of their contents in the preparation of the anatomical papers which pass under his name. After his death appeared his "Treatise on the Blood, Inflammation, and Gun-shot Wounds," preceded by a biography by Sir Everard Home (4to, 1794); and in 1835-'7 his surgical works, with notes by J. F. Palmer, were published in 4 vols. 4to, with an atlas of 60 plates. Biographies of him have also been published by Jesse Foot (8vo, 1794) and Joseph Adams (8vo, 1816). His remains, after a repose of more than half a century under the church of St. Martin-in-the-Fields, were in March, 1859, disinterred by the royal college of surgeons, and on the 28th of the month deposited with much ceremony in Westminster abbey, next to the remains of Ben Jonson.—His wife, ANNE HOME HUNTER (born in 1741, died in 1821), published in 1802 a volume of poems, several of which were set to music by Haydn.

HUNTER, Robert Mercer Taliaferro, an American statesman, born in Essex co., Va., April 21, 1809. He graduated at the university of Virginia, studied law, and commenced practice in 1830. Having served in the Virginia house of delegates, he was in 1837 elected to congress, and in 1839 chosen speaker of the house of representatives. He was defeated in 1843, but re-elected in 1845. In 1846 he was chosen senator in congress, taking his seat in December, 1847. In 1849 he was made chairman of the committee on finance, which post he held until the opening of the civil war. In the mean while he bore a large part in the political discussions of the day. In 1860 he was a prominent candidate for the democratic nomination to the presidency, receiving upon several ballots in the convention at Charleston the next highest vote to that for Mr. Douglas. He took a leading part in the secession movement, and according to the original scheme was to have been president of the new government, Jefferson Davis to be commander-in-chief of the army. He was formally expelled from the United States senate in July, 1861. The confederate plan had been changed, Davis having been made president, and Robert Toombs secretary of state. Toombs was soon superseded by Hunter, and he in a short time by Judah P. Benjamin. Hunter, having been elected senator from Virginia, was classed in the opposition to the administration of Davis. In February, 1865, Hunter, Stephens, and Campbell were appointed peace commissioners to meet President Lincoln and Mr. Seward upon a vessel in Hampton Roads. The conference was futile, Lincoln refusing to treat upon the basis of recognizing the independence of the confederacy. A war meeting was then held in Richmond, over which Hunter presided, and resolutions were passed to the effect that the confederates would never lay down their arms until they should have achieved their independence.

About this time Gen. Lee urged upon the confederate congress the passage of a law authorizing the employment of negroes as soldiers, those thus employed to be made freemen. A bill to this effect was passed in the house of representatives, but was defeated in the senate by a single vote. Mr. Hunter at first voted against it, but having been instructed by the legislature of Virginia to vote for it, he did so, accompanying his vote with an emphatic protest against the passage of the bill, for which he was compelled to vote. He said: "When we left the old government, we thought we had got rid for ever of the slavery agitation. We insisted that congress had no right to interfere with slavery. We contended that whenever the two races were thrown together, one must be master and the other slave. We insisted that slavery was the best and happiest condition of the negro. Now, if we offer slaves their freedom as a boon, we confess that we were insincere and hypocritical. If the negroes are made soldiers, they must be made freemen. If we can make them soldiers, we can make them officers, perhaps to command white men. If we are right in this measure, we were wrong in denying to the old government the right to interfere with the institution of slavery and to emancipate slaves." After the close of the civil war he was arrested, but was released upon parole, and was in 1867 pardoned by President Johnson. In 1874 he was an unsuccessful candidate before the legislature of Virginia for the office of United States senator.

HUNTER, William, a British physician and anatomist, elder brother of John Hunter, born at Long Calderwood, Lanarkshire, May 23, 1718, died in London, March 30, 1783. At the age of 14 he was sent to the university of Glasgow with the intention of studying for the ministry; but in 1737, not being inclined to the study of theology, he went to reside in Dr. William Cullen's family as a medical student. Three years after he formed a partnership with Cullen, by which he was to take charge of the surgical part of their practice. To prepare himself for this he studied in Edinburgh, and in 1741 went to London with letters of introduction to Dr. James Douglass. Douglass offered to employ him as tutor of his son and as dissector for a work on the anatomy of the bones which he was preparing. Hunter accepted the offer. Douglass died the following year, but Hunter continued to reside with the family as tutor, and to pursue his studies in anatomy and surgery. Concluding to remain in London, the partnership with Cullen was dissolved, but they remained warm friends through life. In the winter of 1746 he made his first appearance as a lecturer on surgery before the society of navy surgeons, and such was the favor with which he was received that he was invited to extend his course to anatomy. About the same time he began to acquire an extensive practice both as a surgeon and an accoucheur; but having in 1748 received the

appointment of surgeon accoucheur to the Middlesex hospital, and in 1749 to the British lying-in hospital, he abandoned surgery, and thenceforth devoted himself almost exclusively to obstetrics. About this time he established himself in a house in Jermyn street, where he commenced the formation of a large anatomical museum. In 1754 he entered into a professional partnership with his brother John, whose industry was of great use in adding to the contents of the museum. In consequence of the illness of John, however, the partnership terminated in 1759. In 1762 he officiated as consulting physician to Queen Charlotte, and two years later was appointed her physician extraordinary. In 1762-'4 appeared his "Medical Commentaries, Part I." (4to, London). In 1765 he applied to Mr. Grenville, then minister, for a piece of ground in the Mews for the site of an anatomical museum. Notwithstanding that he offered to expend £7,000 on the building, and to endow a professorship of anatomy, the application was unfavorably received, and he accordingly purchased a spot of ground in Great Windmill street, and erected the necessary buildings, into which he removed in 1770 with his whole collection. From time to time the collections of eminent practitioners were purchased and incorporated with it, and the zeal of friends and pupils procured him a great number of morbid preparations. Not contented with his anatomical collection, he began to accumulate fossils, books, coins, and other objects of antiquarian research. His library was said to contain "the most magnificent treasure of Greek and Latin works accumulated since the days of Mead;" and his coins, of a portion of which a description was published under the title of *Nummorum Veterum Populorum et Urbium, qui in Museo Guilielmi Hunteri asservantur, Descriptio, Figuris Illustrata*, cost upward of £20,000. In 1781 Dr. Fothergill's collection of shells, corals, and other objects of natural history, was added to the museum at an expense of £1,200. The whole collection, with a fund of £8,000 for its support and augmentation, was bequeathed to the university of Glasgow, where, under the name of the Hunterian museum, it is now deposited. In 1774 appeared his *Anatomia Humani Uteri Gravidæ*, in Latin and English (atlas fol., with 34 plates, Birmingham; fol., London, 1828), on which he had been engaged since 1751. It has been called one of the most splendid medical works of the age. A work describing the engravings, entitled "An Anatomical Disquisition of the Human Gravid Uterus and its Contents" (4to, London), was published in 1794 by his nephew Dr. Baillie. The subsequent claim of John Hunter to the discovery of the mode of union between the placenta and the uterus, as described by William in this work, caused a bitter hostility between the brothers, which lasted until the elder was on his deathbed, when a reconciliation took place. In 1768 he

was appointed by the king professor of anatomy in the royal academy of arts. In 1767 he was elected a fellow of the royal society, and two years before his death he succeeded Dr. John Fothergill as president of the medical society. He contributed important papers to the medical and scientific periodicals of the day, and left several lectures and unfinished works in manuscript. He was esteemed one of the chief ornaments of the medical profession in the 18th century, and by his anatomy of the gravid uterus, and his description of varicose aneurism, materially advanced the sciences of anatomy and midwifery.

HUNTERDON, a W. county of New Jersey, separated from Pennsylvania on the W. by Delaware river, bounded N. W. by the Musconetcong, E. in part by the Lamington, and drained by branches of Raritan river; area, 480 sq. m.; pop. in 1870, 36,963. The surface is level in the centre and mountainous toward the N. and S. Limestone and freestone are abundant, and the hills are well timbered. The soil of the valleys is fertile. The New Jersey Central, the South Branch, the Belvidere Delaware, and Flemington branch, and the Delaware, Lackawanna, and Western railroads traverse it. The chief productions in 1870 were 340,393 bushels of wheat, 26,799 of rye, 1,021,251 of Indian corn, 902,737 of oats, 41,527 of buckwheat, 86,807 of potatoes, 67,863 lbs. of wool, 226,936 of flax, 965,243 of butter, and 38,110 tons of hay. There were 9,520 horses, 12,983 milch cows, 7,588 other cattle, 22,790 sheep, and 15-311 swine; 33 manufactories of carriages, 23 of clothing, 2 of cordage and twine, 1 of cotton goods, 2 of mirror and picture frames, 6 of hubs and wagon material, 1 of India-rubber goods, 5 of iron, 24 of masonry, 2 of wrapping paper, 19 of saddlery, 9 of sash, doors, and blinds, 48 flour mills, 24 saw mills, and 2 railroad repair shops. Capital, Flemington.

HUNTINGDON, a S. central county of Pennsylvania, drained by the Juniata river and its tributaries; area, 730 sq. m.; pop. in 1870, 31,251. It has a very diversified surface, occupied in part by mountains, and noted for its fine scenery. Iron, lead, coal, salt, and alum are found, and timber is abundant. The valleys are fertile. The Pennsylvania Central and the Huntingdon and Broad Top railroads traverse it. The chief productions in 1870 were 388,859 bushels of wheat, 78,480 of rye, 503,807 of Indian corn, 410,479 of oats, 148,679 of potatoes, 54,110 lbs. of wool, 465,027 of butter, and 27,815 tons of hay. There were 7,098 horses, 7,120 milch cows, 11,289 other cattle, 17,780 sheep, and 12,909 swine; 15 manufactories of carriages, 7 of clothing, 12 of furniture, 3 of bricks, 2 of bread, 3 of pig iron, 8 of iron castings, 5 of blooms, 5 of plaster, 8 of saddlery and harness, 13 of tin, copper, and sheet-iron ware, 4 of woollen goods, 14 flour mills, 20 tanneries, 9 currying establishments, 1 distillery, 2 planing mills, and 7 saw mills. Capital, Huntingdon.

HUNTINGDON, an extreme S. W. county of Quebec, Canada, divided into two parts by the angle of Chateauguay co., bordering S. on New York, and N. W. on the St. Lawrence river; area, 400 sq. m.; pop. in 1871, 16,304, of whom 6,386 were of Irish, 4,924 of French, 3,184 of Scotch, and 1,033 of English origin or descent. It is drained by the Chateauguay river and other streams, and is traversed by the Province Line division of the Grand Trunk railroad. The surface is undulating and the soil fertile. Capital, Huntingdon.

HUNTINGDON, Selina, countess of, a patron of the English Calvinistic Methodists, born in 1707, died June 17, 1791. She was the daughter of Washington Shirley, earl of Ferrers, and was married to Theophilus Hastings, earl of Huntingdon. The Hastings family early became interested in the Methodists, and through their influence and from severe family afflictions the countess was led to cherish a strong sympathy with the methods and principles of the evangelists, especially Whitefield. She was accustomed to frequent the Moravian societies in London; but at the withdrawal of Wesley she favored the Methodist party, and specially encouraged the leaders in the promotion of a lay ministry, which she considered an absolute necessity to the successful evangelization of the masses. Her house at Chelsea, near London, was the resort of fashionable and aristocratic persons, and after Whitefield was appointed her chaplain many of the wits and scholars of the age became his hearers. Her house was likewise the centre of a circle of women of noble rank, who were zealous in the cultivation of a high-toned piety in an irreligious age. Meanwhile the rapid success of Wesley, Whitefield, and their coadjutors had created a demand throughout the kingdom for chapels and meeting houses for the poor. The countess undertook to supply this need, and promoted in every way the labors of the evangelists. She dispensed with her luxurious equipage, and even sold her jewels, to obtain the means for carrying out her plans. Halls and theatres were purchased in London, Bristol, and Dublin, and fitted up for chapels, and accommodations for the societies were provided in England, Ireland, and Wales. She interested many of the noble and wealthy in her plans, met them in frequent conference, and often accompanied the preachers on their missionary tours. By her advice England was divided into six districts, and a scheme perfected for supplying destitute districts with religious instruction. The pressing need for a larger number of ministers led her at length to found a theological seminary at Trevecca in Wales, where pious candidates for the ministry, irrespective of sectarian character, were provided with board, tuition, and other aid, at the countess's expense. While strongly attached to the church of England, she was at length compelled to the avowal of dissent in order to protect the numerous chapels which she had founded from

suppression or appropriation by the establishment. Hitherto, by her strong practical sense and moral power, she had virtually controlled and directed the movements of Calvinistic Methodism. After the "Lady Huntingdon Connection" had taken their position among dissenters, the countess attempted to devise a plan for a closer and more organic union among the various societies. Its provisions were very similar to Wesley's model. In these attempts, however, she met with very little sympathy from her preachers, and after her death the chapels that she had founded became mostly Independent. At her decease she left £5,000 for charitable purposes, and the rest of her fortune for the support of 64 chapels which she had built.

HUNTINGDONSHIRE, an inland county of England, bordering on Cambridgeshire, Northamptonshire, and Bedfordshire; area, 359 sq. m., being the smallest county of England except Rutland and Middlesex; pop. in 1871, 63,672. The N. portion forms part of the fen district (see BEDFORD LEVEL), and is devoted chiefly to grazing. In the W. and S. parts the surface is slightly varied by the swell of two low ridges of hills. In the S. E. is an extensive plain of fertile land, and along the banks of the Ouse and Nene are rich meadows overflowed at high tides. The general character of the soil is either gravelly or clayey loam. Although the greater part of the county was once a royal forest, it is now very bare of timber. Agriculture is the only industry. The products are wheat, oats, and beans, with some barley, hops, hemp, turnips, and mustard seed. The chief rivers are the Ouse within the county, and the Nene along the border, with their tributaries. There were formerly several small meres or shallow lakes in the county, but these have all been drained and brought under cultivation. The principal towns are Huntingdon, St. Ives, St. Neots, and Ramsay. Huntingdon is on the Ouse, 59 m. N. of London; pop. of the municipal borough in 1871, 4,243. It was the birthplace of Oliver Cromwell.

HUNTINGTON, a N. E. county of Indiana, drained by Wabash and Salamonie rivers; area, 384 sq. m.; pop. in 1870, 19,036. The surface is slightly uneven and the soil fertile. The Wabash and Erie canal, and the Toledo, Wabash, and Western railroad, pass through it. The chief productions in 1870 were 367,521 bushels of wheat, 288,840 of Indian corn, 81,425 of oats, 42,655 of potatoes, 66,257 lbs. of wool, 320,098 of butter, and 12,079 tons of hay. There were 5,902 horses, 5,094 milch cows, 5,582 other cattle, 31,058 sheep, and 20,565 swine; 7 manufactories of carriages, 1 of baskets, 1 of boots and shoes, 4 of furniture, 3 of wagon material, 8 of lime, 5 of saddlery and harness, 2 of cigars, 3 of woollen goods, 3 tanneries, 3 currying establishments, 6 flour mills, and 25 saw mills. Capital, Huntington.

HUNTINGTON. **I. Daniel**, an American painter, born in New York, Oct. 14, 1816. While pursuing his studies at Hamilton college, he

made the acquaintance of Charles L. Elliott, the portrait painter, from whom he received a decided bias for art. In 1853 he entered the studio of S. F. B. Morse, then president of the national academy of design, and soon after produced "The Bar-Room Politician," "A Toper Asleep," &c., besides some landscapes and portraits. In 1836 he spent several months in the vicinity of the Hudson highlands, and executed views near Verplanck's, the Dunderberg mountain, and Rondout creek at twilight and sunset. In 1839 he went to Europe, and in Florence painted "The Sibyl" and "The Florentine Girl." Removing to Rome soon after, he painted "The Shepherd Boy of the Campagna" and "Early Christian Prisoners." Upon his return to New York he was employed for a time almost exclusively upon portraits, his only historical pieces of importance being "Mercy's Dream" and "Christiana and her Children," from "Pilgrim's Progress." For two years he was compelled by an inflammation of the eyes to relinquish his labors, and in 1844 went again to Rome, where he passed the succeeding winter, and whence he sent back to America "The Roman Penitents," "Italy," "The Sacred Lesson," "The Communion of the Sick," and some landscapes. After his return to New York in 1846 he again devoted himself chiefly to portraits. From 1862 to 1869 he was president of the national academy of design. Among his works are "Lady Jane Grey and Feckenham in the Tower," "Henry VIII. and Queen Catharine Parr," "The Marys at the Sepulchre," "Queen Mary signing the Death Warrant of Lady Jane Grey," and another picture of "Mercy's Dream," all of which have been made familiar by engravings. **II. Jedidiah Vincent**, an American clergyman, brother of the preceding, born in New York, Jan. 20, 1815, died in Pau, France, May 10, 1862. He studied medicine and practised for several years, but subsequently took orders in the Episcopal church, officiating for a time as rector in Middlebury, Vt. He afterward went to Europe, where in 1849 he became a Roman Catholic. Returning to America, he edited the "Metropolitan Magazine" in Baltimore, and subsequently the "Leader" in St. Louis. He afterward resided in New York, and finally again went to Europe. He published a volume of "Poems" (1843), and the novels "Lady Alice, or the New Una" (1849), "Alban" (1850), "The Forest" (1852), "Blonde and Brunette" (1859), and "Rosemary" (1860).

HUNTINGTON, **Frederick Dan**, an American bishop, born in Hadley, Mass., May 28, 1819. He graduated at Amherst college in 1839, and spent the three following years in the Cambridge divinity school. In 1842 he was ordained pastor of the South Congregational church in Boston, and in September, 1855, became preacher to Harvard university and Plummer professor of Christian morals. Although educated in the Unitarian belief, his views of

theology gradually underwent a change, and having become convinced that the doctrine of the Trinity is the true doctrine of the Scriptures, he applied for orders in the Episcopal church, was admitted to the ministry in 1860, and resigned his office at Harvard in 1864. He became rector of Emmanuel church, Boston, was elected bishop of Central New York in January, 1869, and was consecrated April 8. His principal publications are: "Sermons for the People" (1856; 9th ed., 1869); "Sermons on Christian Living and Believing" (1860); a course of lectures on "Human Society as illustrating the Power, Wisdom, and Goodness of God" (1860); "Lessons on the Parables of our Saviour"; "Elim," a collection of ancient and modern sacred poetry (1865); "Helps to a Holy Lent" (1872); and "Steps to a Living Faith" (1873). He has also edited various works of the Rev. William Mountford (1846), Archbishop Whately's "Christian Morals" (1856), and "Memorials of a Quiet Life," that is, of the Hare family (1874).

HUNTINGTON, Samuel, one of the signers of the American Declaration of Independence, born in Windham, Conn., July 3, 1732, died in Norwich, Jan. 5, 1796. He was educated to the law, and previous to 1775 held the offices of king's attorney and associate justice of the superior court of Connecticut. In January, 1776, he entered the continental congress as a delegate from his native state. In September, 1779, he succeeded John Jay as president of congress, and filled that office till 1781, when he resumed his seat on the Connecticut bench. He served again in congress, from May to June, 1783, and in the succeeding year was appointed chief justice of the superior court of Connecticut. In 1785 he was elected lieutenant governor of Connecticut, and in 1786 he succeeded Roger Griswold as governor, to which office he was annually reelected until his death.

HUNTINGTON, William, an English preacher, born in 1744, died at Tunbridge Wells in August, 1813. His early life was passed in menial service and dissipation; but having been converted he came to be a zealous preacher among the Calvinistic Methodists, travelling through the country, and gaining many followers. He finally settled in London, and having married for his second wife the widow of a rich alderman, his later years were spent in affluence. He published a great number of discourses and tracts, which were collected in 20 vols. (London, 1820). A selection from these was published by his son (6 vols., London, 1838; 2d ed., 1856). To his name he appended the letters S. S., which he thus explained: "As I cannot get a D. D. for the want of cash, neither can I get an M. A. for want of learning; therefore I am compelled to fly for refuge to S. S., by which I mean sinner saved."

HUNTSVILLE. I. A city and the capital of Madison co., Alabama, on the Memphis and Charleston railroad, about 10 m. N. of the Tennessee river, and 165 m. N. of Montgom-

ery; pop. in 1870, 4,907, of whom 2,375 were colored. It is noted for its magnificent scenery, is well built, and contains a handsome court house and other public buildings, a foundry, two planing mills, gas works, water works, a bank, a tri-weekly and two weekly newspapers, and 11 churches, of which 5 are for colored people. Huntsville female seminary, under the charge of the Presbyterians, organized in 1829, in 1872 had 7 instructors and 101 students. Huntsville female college, Methodist, organized in 1853, had 11 instructors and 132 students. **II.** A town and the capital of Walker co., Texas, at the terminus of a branch (8 m. long) of the International and Great Northern railroad, about 12 m. S. W. of Trinity river and 135 m. E. by N. of Austin; pop. in 1870, 1,599, of whom 638 were colored. It is pleasantly situated on high ground, in the midst of a rich cotton region, has an active business, is well built, and is the seat of Austin college, a flourishing institution under the care of the Presbyterians, of the Andrew female institute (Methodist), and of the state penitentiary. The penitentiary was built in 1848-'9, and has a large tract of land connected with it, and facilities for the manufacture of cotton and woolen goods. A semi-weekly and a weekly newspaper are published.

HUNYADY, János (JOHN HUNNADES), a Hungarian general and statesman, born toward the close of the 14th century, died in 1456. His birth and youth are wrapped in legendary obscurity, as is the origin of his surname Corvinus (Hollósi). Under the reign of Albert (1437-'9) he became ban of a province south of the Danube, and under Uladislav I. (1439-'44) count of Temes and commander of Belgrade. Shortly after the latter appointment he repulsed a Turkish army of invasion from his province, and soon after routed the same in Transylvania (1442). In the following year he made a victorious campaign through Servia and across the Balkan, which conquered peace from the Turks. Uladislav, however, was induced by the legate of Eugenius IV. to break it, and perished with the greater part of his army at the battle of Varna (1444). Hunyady, who escaped, was made governor of Hungary during the minority and absence of Ladislav the Posthumous, son of Albert, who was detained by the emperor Frederick III. In 1448 Hunyady was defeated by Sultan Amurath at Kosovo, on the confines of Servia and Bulgaria, but in 1454 he was again victorious over the enemies of his country and Christendom, whose expulsion from Europe he made the task of his life. The heroic defence of Belgrade closed his career. Of his two sons, Ladislav died innocently on the scaffold, and Matthias (Corvinus) ascended the throne of Hungary.

HUPPAZOLI, Francesco, a Piedmontese centenarian, who lived in three centuries, born in Casale in March, 1587, died Jan. 27, 1702. His parents sent him to Rome to be educated, and obliged him to enter holy orders. He

travelled in Greece and the Levant, and in 1625 was married at Scio and engaged in commerce. At 82 years of age he was appointed consul of Venice at Smyrna. His habits were regular; he drank no fermented liquors, ate little, and chiefly of game and fruits, never smoked, and went to bed and rose early. He was sick for the first time in 1701, when he had a fever which lasted 15 days, and he remained deaf for three months after his recovery. At the age of 100 years his hair, beard, and eyebrows, which were white, became again black. At the age of 112 years he had two new teeth, but lost all his teeth before his death, and lived on soup. He suffered in the last year of his life from the gravel, and died of a cold. He was five times married, and had 24 legitimate and 25 illegitimate children. By his fifth marriage, which took place in his 99th year, he had four children. He left a journal of the principal events of his life.

HURD, Richard, an English prelate, born at Congreve, Staffordshire, in 1720, died at Hartlebury in 1808. He was the son of a farmer, and was educated at Cambridge, where he became a fellow of Emmanuel college in 1742. He continued to reside at Cambridge till 1757, when he became rector of Thurcaston. He was preacher to the society of Lincoln's Inn in 1765; archdeacon of Gloucester in 1767; bishop of Lichfield and Coventry in 1775; preceptor to the prince of Wales and the duke of York in 1776; and bishop of Worcester in 1781. In 1783 George III. offered him the archbishopric of Canterbury, but he declined it. His principal publications are: "Commentary on Horace's *Ars Poetica*" (1749); "Dialogues" (1758); "Select Works of Abraham Cowley" (1769); "Introduction to the Study of the Prophecies" (1772); several volumes of "Sermons" (1776-80); "Works of Bishop Warburton" (7 vols. 4to, 1788); "Life of Warburton" (1794); and "Addison's Works" (6 vols., 1810). There is a collection of his works, with an autobiography (8 vols., 1811).

HURDWAR, a town of British India, in the province and 100 m. N. N. E. of the city of Delhi; pop. about 5,000, besides many fakirs or members of the mendicant order, who dwell in caves. It is a celebrated place of pilgrimage, beautifully situated at the foot of the Himalaya mountains, and on the right bank of the Ganges. Immense multitudes annually assemble here at the vernal equinox to bathe in the river, the religious ceremony consisting only in immersion; but the desire of being among the first to plunge into the water is so strong that the crowding on the narrow passage leading to the bathing spot has often been attended with riotous disturbances. Every 12th year is regarded as especially holy, and as many as 2,000,000 pilgrims are said to assemble on such occasions. The fairs held at the time of the pilgrimage are renowned.

HURLBERT, William Henry, an American journalist, born in Charleston, S. C., July 3, 1827.

He graduated at Harvard college in 1847, and at the Cambridge divinity school in 1849. After preaching for some time at Salem, he went to Europe in 1849 and attended the lectures of Ritter, Von Raumer, and Ranke at Berlin, and returning to Cambridge in 1851 studied during the two following years in the law school. In 1855 he went to New York, joined the staff of "Putnam's Monthly" magazine, and was dramatic critic of the "Albion." From February, 1857, till after the presidential election of 1860, he was on the staff of the New York "Times." In 1861 he was a delegate to the peace convention at Albany. In June of that year, having gone on private business to Charleston, he was arrested as a suspected emissary from the north, and without trial was sent to Richmond, where he was imprisoned 14 months, but made his escape through the lines to Washington in September, 1862. In October following he joined the editorial staff of the New York "World," and is still (1874) connected with that journal. He has been an indefatigable traveller, and in the discharge of his professional duties has visited at different times nearly every part of Europe, has been three times to Mexico, and has made extended tours in Central and South America. In 1867 he attended and reported for the "World" the celebration of the 18th centenary of the martyrdom of St. Peter at Rome, and in the same year the meeting of the emperors of Austria and France at Salzburg; in 1869 he was present at the opening of the Suez canal and the subsequent fêtes at Constantinople; in 1869-'70 he attended the opening and session of the œcumenical council at Rome; in 1871 he accompanied and reported the proceedings of the United States commission to Santo Domingo; and in 1873 he described in a series of letters the first passage by steam of the higher Andes of Bolivia, and wrote fully concerning the earthquakes of San Salvador. He has written numerous poems, including hymns that hold a place in Unitarian collections; has published "Garden, or Pictures of Cuba," written during a health trip to that island in 1853 (Boston, 1854, and London, 1855), and "General McClellan and the Conduct of the War" (New York, 1864); has contributed to numerous periodicals in the United States and Great Britain; and is now (1874) preparing a work on the Pacific countries of South America.

HURLBUT, Stephen Augustus, an American soldier, brother of W. H. Hurlbert, born in Charleston, S. C., March 24, 1815. He served as adjutant of a South Carolina regiment in the Seminole war in 1835, and practised law in Charleston till 1845, when he removed to Belvidere, Ill. He was a delegate to the state constitutional convention in 1847, and subsequently was repeatedly elected to the legislature. In May, 1861, he was appointed a brigadier general of volunteers, commanded at Fort Donelson after the capture, commanded the 4th division

in Gen. Grant's army in the movement up the Tennessee river, took part in the battles of Shiloh and Corinth, held command at Memphis in 1863, commanded a corps in Gen. Sherman's army in the movement to Meridian in 1864, succeeded Gen. Banks in command of the department of the gulf in May, 1864, and was mustered out of the service at the close of the war. He was minister to the United States of Colombia from 1869 to 1873, when he returned to Illinois, having been elected a member of congress.

HURON. I. A N. county of Ohio, drained by Huron and Vermilion rivers; area, 455 sq. m.; pop. in 1870, 28,532. It has a nearly level surface, and an excellent sandy soil. The Cleveland, Columbus, Cincinnati, and Indianapolis, the Lake Erie division of the Baltimore and Ohio, and the Lake Shore and Michigan Southern railroads pass through it. The chief productions in 1870 were 472,496 bushels of wheat, 777,083 of Indian corn, 519,905 of oats, 169,312 of potatoes, 445,909 lbs. of wool, 809,801 of butter, 60,842 of cheese, and 43,747 tons of hay. There were 8,550 horses, 10,113 milch cows, 10,182 other cattle, 92,627 sheep, and 15,244 swine; 5 manufactories of agricultural implements, 2 of boots and shoes, 12 of carriages, 2 of cheese, 12 of cooperage, 5 of iron castings, 2 of machinery, 1 of malt, 12 of saddlery and harness, 1 of sewing machines, 7 of tin, copper, and sheet-iron ware, 5 tanning and currying establishments, 4 distilleries, 1 brewery, 7 flour mills, 2 planing mills, and 15 saw mills. Capital, Norwalk.

II. An E. county of Michigan, forming the extremity of a point of land between Lake Huron on the E. and N. E. and Saginaw bay on the N. W.; area, 850 sq. m.; pop. in 1870, 9,049. The surface is nearly level, watered by Pigeon, Willow, and Berry rivers, and in some places marshy. Most of the county is covered with forests, from which in 1872 were produced 49,000,000 ft. of lumber. There are also salt wells, from which were obtained 30,615 barrels of salt. The chief productions in 1870 were 58,251 bushels of wheat, 50,194 of oats, 20,778 of peas and beans, 99,005 of potatoes, 10,097 lbs. of wool, 131,265 of butter, and 7,597 tons of hay. There were 624 horses, 1,788 milch cows, 1,197 working oxen, 1,596 other cattle, 2,576 sheep, and 1,933 swine; 4 manufactories of barrels and casks, 2 of hones and whetstones, 1 of salt, and 29 saw mills. Capital, Port Austin.

HURON, a W. county of Ontario, Canada, bordering on Lake Huron, and watered by the Maitland and its tributaries; area, 1,288 sq. m.; pop. in 1871, 66,165, of whom 23,740 were of Irish, 19,388 of Scotch, 16,558 of English, and 5,220 of German origin or descent. It is an excellent farming region, and has good facilities for lumbering and ship building. Near Goderich are extensive salt wells. The county is traversed by the Grand Trunk railway. Capital, Goderich.

HURON, Lake, one of the great lakes on the boundary between the United States and British America, lying between lat. 43° and 46° 15' N., and lon. 80° and 84° 40' W. It receives at its N. extremity the waters discharged from Lake Superior by St. Mary's river or strait, and also those of Lake Michigan through the strait of Mackinaw. Its outlet at the S. extremity is the St. Clair river. It is bounded W. and S. W. by the southern peninsula of Michigan, N. and E. by Ontario, Canada. Georgian bay, 120 m. long and 50 m. wide, lies wholly within Ontario, and is shut in from the main body of the lake by the peninsula of Cabot's head on the south and the Manitoulin chain of islands on the north; and N. of these islands is Manitou bay or the North channel. The whole width of Lake Huron, including Georgian bay, is about 190 m., and its length about 250 m. Its area is computed to be about 21,000 sq. m. Its elevation above the sea is rated by the state engineers of Michigan at 578 ft.; the Canadians make it 3 ft. less. The level of its waters fluctuates several feet at irregular periods, as is observed also of the other lakes. Various estimates are made of its average depth, the least being 800 ft., and the highest, which is that of the Michigan state report of 1838, 1,000 ft. In this report it is stated that soundings have been made in the lake of 1,800 ft. without finding bottom. Few harbors are found along the W. shore of Lake Huron. About 70 m. N. of the outlet Saginaw bay sets back into the land a distance of 60 m. toward the S. W., and under its islands and shores vessels find shelter from the storms which prevail from the N. E. or S. W. up and down its wide mouth and across the broadest expanse of the lake. Thunder bay is a much smaller extension of the lake into the land, about 140 m. from the outlet. Steamers usually stop here for supplies of wood, chiefly pine and birch, which, with the white pine largely cut for lumber, and excellent grindstones obtained from the sandstone rocks, constitute the only valuable products of these shores. At Presque Isle, 28 m. further N., is another harbor, where the land turns round toward the N. W., and a straight course is thence made for Mackinaw, 70 m. distant. This island is famous as a trading post and fort in the history of the northwest and of the fur trade, and is still a point of importance on the lake. The harbor is deep and well sheltered, on the S. side of the island, under high hills, upon which stands the United States fort. The fishing business is extensively carried on, whitefish of excellent quality abounding in the lake near by, and those of the northern part of Lake Michigan also finding a market here.—The shores on the Michigan side present few features of interest. The rock formations are sandstones and limestones of the several groups from the Helderberg to the coal measures, the latter being found in the upper portion of Saginaw bay, where, however, they are of little

importance. Beaches of sand alternate with others of limestone shingle, and the forests behind are often a tangled growth of cedar, fir, and spruce in impenetrable swamps, or a scrubby scattered growth upon a sandy soil. Calcareous strata of the upper Silurian stretch along the E. coast from the outlet nearly to Georgian bay, and are succeeded by the lower members of the same series down to the Hudson river slates and the Trenton limestone, which last two stretch across from Lake Ontario to Georgian bay. In the metamorphic rocks found in the upper portions of Manitoulin bay copper ores begin to appear, and have been worked at the Bruce mines. With the change in the rock formations the surface becomes more broken and hilly, rising to elevations 600 ft. or more above the lake.—The rivers that flow into Lake Huron are mostly of small importance. The principal streams from Michigan are Thunder Bay river, the Au Sable, and the Saginaw; from Ontario, the French (outlet of Nipissing lake), the Muskoka, the Severn (outlet of Lake Simcoe), and the Nottawasaga, all emptying into Georgian bay, and Saugeen, Maitland, and Aux Sables. The chief towns on its shores are Collingwood and Owen Sound (on Georgian bay), Goderich, and Sarnia (at the entrance of St. Clair river), in Ontario; in Michigan, Bay City at the head of Saginaw bay, and Port Huron opposite Sarnia. The season of navigation in Lake Huron is usually from the last of April or early part of May into December; and the finest season, during which the waters often continue smooth and the air mild and hazy for two or three weeks, is the latter portion of November.

HURONS, a once powerful tribe of American Indians, originally occupying a small territory near Georgian bay, a part of Lake Huron. They were the most northwesterly branch of the Huron-Iroquois family, the Hochelagas, occupying Montreal island in Cartier's time, being the most easterly, and the Tuscaroras the most southerly. When the French under Champlain began to occupy the St. Lawrence in 1609, the Hurons were allies of the Algonquins and Montagnais against the Iroquois or Five Nations, the most powerful tribe of the family to which the Hurons belonged. Champlain joined the alliance, and in 1609 accompanied a Huron-Algonquin party on an expedition, which defeated an Iroquois force on Lake Champlain. In 1615 he went up to the Huron country with the Franciscan missionary Joseph le Caron, and thence accompanied the Hurons on an expedition against a tribe in New York, belonging or allied to the Five Nations. The Franciscans continued missions among the Hurons till 1629, and Frère Sagard in his *Grand voyage au pays des Hurons* (Paris, 1632), and *Histoire du Canada* (Paris, 1636), describes them fully and gives a dictionary of their language. They consisted of four divisions: Attignawantans, Attigneononguahac, Arendahronon, and Tohonteenrat; the first and second being

primitive, and the others subsequently adopted. They called themselves, as the Iroquois did, Ontwaonwes, real men, and as a tribe Wendat. Their country was of very limited extent for an Indian tribe, being only about 75 m. by 25, lying, as was estimated, in lat. 45° 30' N., near Lake Huron. In this space there were 30,000 Hurons in 25 towns of various size, Ossossane being the chief one. Those on the frontiers were fortified by a triple palisade, and gallery within, while many of the others were unprotected. The houses were long, containing several families, two to each fire; they were built of poles covered with bark. The Hurons raised corn, squashes, beans, and tobacco. When Canada was restored in 1632, the Jesuits began their famous Huron missions, which lasted till the destruction of the nation. Diseases had greatly enfeebled them. Then the Iroquois, supplied with firearms by the Dutch, took Ossossane in 1648, killing the missionary Daniel among his flock; the next year two other large towns were destroyed, Brebeuf and Lalemant perishing at the stake. The Hurons then dispersed. The Tohonteenrat surrendered in a body and removed to the Seneca country. The rest fled to Charity island in Lake Huron and to Manitoulin, but famine swept many off. In 1650 Père Ragueneau led a few hundred to Quebec, who were placed on Isle Orléans, and were soon joined by those left at Manitoulin. In 1656 the Mohawks carried off a number before the eyes of the French garrison, and the Onondagas compelled others to join their canton. Under more vigorous French rule the Hurons began to thrive, and in 1667 they removed to Notre Dame de Foye, and in 1693 to Lorette, then after a time to Jeune Lorette, which has since been their abode. It is 8 or 9 m. from Quebec, on the river St. Charles, on an eminence, and consists of 40 or 50 houses of stone and wood. Their number in 1736 was reported at 60 or 70 men able to bear arms, and these by 1763 were reduced to 40. In 1815 the tribe numbered 250, and the official report of the Canadian government in 1872 gives 264, although in 1870 there were 329 reported. There are few of pure blood. Their own language has been superseded by French, and they have long been practical Catholics.—Their early Huron cosmogony was curious. A woman, Ataensic, flying from heaven, fell into an abyss of waters. Then the tortoise and the beaver, after long consultation, dived and brought up earth on which she rested and bore two sons, Tawescaron and Iouskeha, the latter of whom killed his brother. The son of Iouskeha, called Tharonhiawagon or Aireskoi, was the great divinity worshipped by the Hurons and Iroquois. The tribe was divided into clans or families, and governed by sachems hereditary in the female line. The totem of the whole nation was the porcupine. The Tionontates, called by English colonial writers Dinondadies, were neighbors of the Hurons, and were crushed soon

after them. These fled to Wisconsin, and are also called Hurons, but after their removal to Sandusky they assumed the name Wyandot. (See WYANDOTS.) A grammar of the Huron language, compiled by Père Chaumonot, founder of Lorette, was published at Quebec in 1831.

HURRICANE (Span. *huracan*), a word of undetermined origin, signifying a violent storm of wind and rain, generally accompanied with intense displays of lightning and thunder. Although this term was originally special in its application, it is now frequently used to designate not a peculiar class of storms, but in general the strength of the most violent winds known to mariners; thus we may have storms in any part of the world whose severest winds may attain to the force either of a gale, a storm, or a hurricane, according to the circumstances that attend their development. The hurricanes of the Pacific ocean, the China sea, and the northern portions of the Indian ocean are called typhoons, and are from a scientific as well as a practical point of view to be classed in the same category with the hurricanes proper; but in what follows we shall give only such facts and theoretical views as belong specially to the hurricanes of the Atlantic and southern Indian oceans. The general subject of storms in their various aspects will be treated under that title.—To a person occupying a stationary position toward which a hurricane is approaching, it is said that the storm is frequently heralded a day beforehand by a peculiar haziness of the atmosphere, a cessation of the regular trade winds, a lassitude perhaps induced by the hygrometric condition of the air, and an ominous stillness. Then follow a steady slow fall of the barometer, light breezes increasing to high winds from some new quarter of the compass, generally in the West Indies between S. E. and N. E., and the obscuration of the entire heavens by a uniform sheet of cloud of increasing density. When the storm has, in the course of from 4 to 24 hours, finally arrived at its greatest severity, the fury of the wind and the confusion of the scene become indescribable; in the midst of a drenching rain and a steady wind that fills the air with a deafening roar, there occur prolonged gusts whose violence equals or excels the force of the strongest waves; in such gusts the largest trees are uprooted, or have their trunks snapped in two, and few if any of the most massive buildings stand uninjured. In the midst of the confusion incident to the general destruction of property and life, there occurs a mysterious calm, while a break in the clouds and the diminished rainfall seem to denote the end of the storm. But in the course of from five minutes to five hours the wind bursts with additional force from a direction opposite to that which had before prevailed; whatever had escaped the destructive force of the first half of the hurricane is likely to yield to its subsequent fury, and the shipping which before perhaps had been blown out

to sea, is now driven back upon the shore. If now, instead of watching the storm from a fixed standpoint, we take a general survey of the ocean over which it rages, we shall observe that the interval of calm in the midst of the storm, as observed at the fixed station, corresponds to a central spot in a large region of violent winds and heavy rain; these winds are found to blow in spiral lines toward and around the central region of calms, increasing in force as they approach that centre. It will also be seen that the whole system of winds moves bodily over the surface of the earth. It is thus easily understood why the stations over which the centre of the hurricane passes should experience, after the central lull, a wind from the opposite quarter to that which prevailed immediately before.—In the "Philosophical Transactions" for 1698 Langford represents the hurricanes of the West Indies as whirlwinds advancing in a direction opposite to that of the trade wind. Dampier (1701) says the West Indian hurricanes and the Chinese typhoons are of the same nature. In 1801 Capper published a work on winds and monsoons, in which he advanced the opinion that the hurricanes at Pondicherry (1760) and Madras (1773) were of the nature of whirlwinds whose diameter would not exceed 120 miles. In 1820 and 1826 Brande broached the theory that the currents of air in great storms flow from all directions toward a central point. Dove (1828), in controverting the views of Brande, explained the observed directions of the winds on the assumption of general rotary currents or whirlwinds. In 1831 Mitchell expressed the opinion that the phenomena of storms are the result of a vortex or gyrotory motion. The scanty observations accessible to the authors previously mentioned were supplemented in 1831 by Mr. Redfield of New York, who then published the first of a series of remarkable papers on the phenomena of storms, in all which he maintained that hurricanes were progressive vortico-se whirlwinds. His views were for a long time controverted in America by Espy and Hare. Sir William Reid published his first papers on hurricanes in 1838, and subsequently other works, in which he developed views similar to those of Mr. Redfield. Of the authors previously mentioned, some laid a special stress on the tangential, and others on the centripetal movements of the winds; at present, however, following the studies of Redfield (1839-'56), Espy (1840-'57), Thom (1845), Piddington (1839-'54), Reid (1838-'50), Ferrel (1858), Meldrum (1851-'73), Mohn (1870), Reye (1872), and many others, it is generally acknowledged that the combination of both these movements with an upward one is an essential feature of every hurricane, so that the movement of the surface wind is more correctly described as an ascending spiral. Concerning the direction of this movement, Dove, and independently of him Redfield, concluded that in the storms of Europe and the American coast the winds move

in a circuit about the storm centre, contrary to the direction of the motion of the hands of a watch when the latter is laid on the ground with its face upward. Furthermore, Dove made the important remark that in the hurricanes of the southern hemisphere the air revolves in an opposite direction; this generalization, announced by him, apparently with some limitations, was by the labors of Reid (1838) converted into an accepted law. The law of the rotation of winds around the storm centre is considered to be of the highest importance in its practical bearings on the interests of navigation, and may be stated in other words as follows: If in the northern (or southern) hemisphere you stand with the centre of the hurricane on your left (or right) hand, the wind will be on your back. The determining cause of this law of rotation, and of the distinction between the hurricanes of the northern and southern hemispheres, was imperfectly understood by early writers, as Taylor and Herschel, but was rigidly demonstrated in a remarkable mathematical memoir by Ferrel in 1858, who showed that the rotation of the earth on its axis affects the direction not merely of north and south winds, but of every wind, in such a manner that in the northern hemisphere winds tend as they move forward to deflect to the right hand, but in the southern hemisphere to the left hand. This tendency, which is known either as Poisson's or as Ferrel's law, is in large storms sufficient to determine the direction of rotation, while in storms of comparatively small dimensions accidental circumstances may conspire to annul or even reverse the direction of rotation. Thus we are provided with the means of harmonizing, at least in great part, the views of Hare, Espy, and others, with those of Redfield and Reid.—There are unfortunately but few actual measurements of the velocity of the stronger winds that occur within the limits of a hurricane. In general it appears that the velocity increases as we proceed from the outer limits toward the centre of the storm, but suddenly diminishes to feeble irregular winds and calms within the central space. From the observed destructive force of some gusts it has also been contended that a velocity of 10 m. per minute must have been momentarily attained, but such computations are not very satisfactory. The highest hurricane winds that have ever been actually observed have on the British coast attained a velocity of 130 m. per hour; in the comparatively small hurricane of August, 1871, the observers in Florida of the United States army signal corps recorded a velocity of 85 m. per hour; all these winds of course were interspersed with gusts of great violence. The diameter of the region of calms varies from 30 m. to a much smaller size, and probably even to nothing. It would seem that in some hurricanes, as frequently in the smaller tornadoes on land, the so-called axis of the storm rises temporarily above the surface of

the earth. The central space in general, according to Redfield, increases in diameter as the storm moves away from the equator northward or southward.—A heavy rainfall extending far beyond the region of most violent winds attends all hurricanes. The quantity of water that falls during the prevalence of these storms forms a large percentage of the total annual rainfall over the hurricane regions, and in this respect they perform an important service to mankind. At Mauritius in the Indian ocean a single storm has been known to be attended by a rainfall of more than 10 inches. The area of cloud and rain is especially extended on the N. and E. quadrant of the storms of the North Atlantic; it is sometimes much contracted, though rarely wanting, on the west side of the hurricanes of both the northern and southern hemispheres. The movements of the clouds have been carefully observed, especially by Redfield (1832-'42) and Ley (1866-'70), and the result is well expressed by Reye (1872): "While on the earth's surface the storm wind in spiral curves gradually flows inward, it forces the flying storm clouds in spiral curves outward, and removes them away from the axis of the cyclone." This generalization was fully explained from a theoretical mechanical point of view by Ferrel, and was shown by him to be a consequence of the rising or upward movement of the masses of air that are drawn into the whirlwind. The clouds then must move in spirals opposed to the movements of the lower winds. Redfield estimates the angle between the winds below and the clouds above to be about 22.5°.—The barometric disturbance is one of the most remarkable features of a hurricane. The nearer one approaches the centre, the lower is the barometric pressure, and at the centre the depression is frequently two or three inches. The first notice of an approaching hurricane, when it is yet 100 to 400 m. distant, is usually given by the steady fall of the barometer; as we approach the centre the fall is more rapid. The law by which the pressure diminishes, as well as the variations from it, may be illustrated by two examples, the first showing a very regular depression, the second giving a great and rapidly increasing rate of fall. The first example is Redfield's Cuba hurricane of Oct. 4-7, 1844, for which we have the following pressures: at the centre, 27.7 in.; at 100 m. distance, 28.0 in.; at 200 m. 29.0 in.; at 300 m., 29.5 in.; at 400 m., 29.8 in. The second example is from Buchan (1871), and relates to the Bahama hurricane of October, 1866. On the evening of the 1st of October we have the following pressures: at the centre, 27.7 in.; at 15 m. distance, or the radius of the central column, 27.8 in.; at 300 m., 29.7 in.; at 500 m., 29.8 in.; and at 800 m., 30.0 in. The ratio at which at a fixed station the barometer falls on the approach of a hurricane differs from the preceding by reason of the progressive motion of the storm toward or

from the station; on board a vessel, the barometric fall is further complicated by the movement of the observer. The best idea of the barometric disturbance is given by a chart of synchronous observations on which isobarometric lines are drawn. These isobars will be found to be crowded together on one side (generally the advancing half) of the storm more than on the other, and to enclose a small oval or circular region of lowest pressure, almost if not quite identical with that of the area of calms, though sometimes apparently in advance of it. In a general way it may be stated that the velocity of the wind increases with the crowding of the isobarometric lines. The exact relation between the two is quite complicated, and may be deduced from the formulas of the above mentioned treatise by Ferrel, combined with the considerations introduced by Peslin in 1867 and Reye in 1872. It is evident that the law above given for the rotation of the wind may be converted into a rule for finding the centre of calms, which will also hold good for finding the centre of lowest barometer; this latter is generally spoken of as the storm centre or axis. Buys-Ballot has expressed this generalization in the form known as Buys-Ballot's rule, viz.: in the northern hemisphere stand with your back to the wind, and the lowest pressure will be on your left hand and somewhat in front thereof; a rule that applies especially to, and was apparently suggested by, the behavior of the winds of hurricanes and similar storms.—The dimensions of hurricanes generally increase from day to day until the dissipation of the entire storm, while the intensity of the winds is believed on the average to diminish somewhat; this will however depend upon the atmospheric conditions favoring the development or the decadence of the disturbance. Given a proper supply of warm moist air, and it can be shown that the central depression with the attendant wind and rain must steadily increase up to a certain limit. These favorable circumstances are generally found combined in a remarkable degree in the region of the Gulf stream, the Kuro Siwo, and similar ocean currents; accordingly, on reaching these the area of cloud and rain expands, as also do the diameters of the isobaric curves. The dimensions of the central depressions vary quite irregularly, but appear on the average to increase as the storm continues; while the actual height of the barometer at the centre changes much less, but is believed to diminish gradually so long as the intensity of the wind increases. If a curve, enclosing a region in which the winds attain the force ordinarily described as a moderate gale, be assumed as the limit of the storm, it will be found that in the earliest stages of the hurricane it has a diameter of from 50 to 200 m., which increases in the course of 5 or 10 days to from 400 to 1,200 m.; thus a disturbance that may have been originally designated as small or local, increases so as to involve half

the surface of the North Atlantic ocean.—The track of the centre of the hurricane is a fair indication of the progress of the storm over the earth, and much labor has been bestowed upon such collations of logs of vessels as would elucidate this important branch of the subject. But notwithstanding the labor expended, there have as yet been very few hurricanes traced back to what appears to be very near their origin, and in not a single instance has unmistakable evidence of their origin been adduced. The general position of hurricane tracks in the earlier parts of their course therefore remains obscure, although the immense accumulation of material by the labors of the various national government weather bureaus is rapidly dissolving our ignorance on this point. So far as the known hurricane tracks are concerned, it may be stated that in the North Atlantic ocean each uniformly appears to be a segment of a parabola having its axis coincident with the parallels of 25° to 35° N. latitude, and the longitudes of whose apices fall between the meridians 40° and 160° west of Greenwich, but mostly between 65° and 85°. At the southern extremity of the parabolic track, the branch passes either to the north of or over the Windward islands, while the northern branch passes to the south of or over Newfoundland. In a few cases the first portion of the track has been traced southeastward nearly to the coast of Senegambia, and the latter portion of the track northeastward to the ocean between Iceland and Scotland; some tracks that curve northeastward before reaching lon. 40° may even strike England or France. The hurricanes of the southern hemisphere describe similar parabolic tracks, which lie at a corresponding distance south of the equatorial belt of calms, and are symmetrically disposed with reference thereto. Very few have been traced in the South Atlantic ocean, but in the southern Indian ocean the majority of the hurricanes pass from Sumatra and Java southwestward to within 500 m. of Madagascar, then southward and southeastward. In general, Mohn (1870) and Reye (1872) state that all cyclones (of which hurricanes are the grandest examples) move in the direction in which for the longest time the warmest and moistest air has been rising, and producing the heaviest cloud and rainfall. If we combine with this law the tendency of the whirlwind as a whole to move away from the equator, as proved by Ferrel, it seems to the writer that we have a very close approximation to the full statement of the reason for the parabolic form of their orbits.—The rate of progression of the West Indian storm centres varies from 50 m. per hour in a few cases to 10 or 15 as the other extreme; that of the storms of the southern Indian ocean varies from 1 to 20 m. The rate in general in the North Atlantic increases with the growth and northward movement of the hurricane, and, though sometimes quite variable, is not so much so as in the case of the similar

storms of the Indian ocean. The rate of progress must be carefully distinguished from the velocity of the wind, as the latter has no known relation to and far exceeds the former. —The waves and swells produced by the hurricane winds are a most important feature; these waves are the largest and most formidable known to the mariner. They form with greatest regularity at points directly in advance of the approaching storm centre; at other points they form a confused mass of crossed sea; in the neighborhood of the land the confusion is increased by the waves reflected from the shores. Such is the equality of the contest of opposing waves, that near the central region these sometimes lose their progressive movement and become stationary pyramidal waves, simply rising and falling. The smaller waves that are propagated in all directions from the region of severest winds, degenerate into long gentle swells that outrun the storm in its progress, and announce its presence several hours or a day in advance of its arrival. Besides these waves, it is believed that the extended region of low barometer allows the formation of a peculiar "cyclone wave," which is similar to the tidal wave of mid-ocean. The cyclone wave is coextensive with the area of low barometer; it is highest at the central lowest pressure, where its elevation above the ordinary sea level should be a foot or more for each inch of barometric depression.—From the earliest times the months from July to October have been known in the West Indies as the "hurricane season." A table published by Poey in 1855 gives the distribution by months of 355 hurricanes recorded on the Atlantic between 1493 and 1855. According to this work, there are recorded in this period in all in January 5, February 7, March 11, April 6, May 5, June 10, July 42, August 96, September 80, October 69, November 17, December 7; but the annual period is probably not very correctly shown by this list, because of the imperfections of the earlier records. More recently Poey has revised his list and added many later hurricanes, and has published in the Paris *Comptes Rendus* for Nov. 24, 1873, and Jan. 5, 1874, the results of a comparison between hurricanes and the frequency of solar spots. His results seem to remarkably confirm those of Meldrum, who had previously studied the hurricanes of the Indian ocean from the same point of view. Poey states that in the majority of cases the years of the greatest number of hurricanes are also the years of the greatest sun-spot frequency. The extensive researches of Köppen (1873) have shown that the amount of heat received from the sun varies annually with the sun spots, whence we infer that the variations in solar heat produce a similar variation in the terrestrial evaporation, and an increased tendency to the formation of hurricanes. The actual number of hurricanes visiting any limited region is of course very small. Since the year

1700 the centres of about 25 have been known to pass quite near the coast of Georgia and South Carolina, which is by far the most frequently visited portion of the United States. Nearly all those of the Indian ocean pass near to the islands of Mauritius, Rodriguez, &c.—Concerning the origin and cause of the hurricanes of the Atlantic ocean comparatively little is positively known, but it seems by analogy that they may originate wherever the lower stratum of warm moist air is rapidly elevated above the sea level, whether (1) by being pushed up over an elevated plateau or mountain chain, or (2) by the under-running of a layer of cold dry air, or (3) by the conflict of two opposed and nearly balanced currents of warm moist air. In numerous instances one or the other of these cases seems to have occurred; and as these, combined with (4) the radiation of heat into space, are the prevailing causes that determine the origin and growth of storms in general, there seems no reason in the case of hurricanes to appeal to more forced theories. The immense mechanical power stored up in the heat and vapor of moist air has been abundantly demonstrated by Espy, Peslin, and Reye. Whenever, by the action of either of the four causes just mentioned, the process of condensation of vapor into cloud, rain, or snow begins, there at once occurs an influx of air from all sides, and from below as well as from above, to fill up the partial vacuum thus created; this influx toward a central region is immediately followed, as shown by Ferrel, by the formation of a whirl whose subsequent development is entirely dependent on the supply of moist air. The hurricanes of the southern Indian ocean are thus generated in the region of calms between the N. W. monsoons and the S. E. trade winds of that ocean. Similarly hurricanes have been known to originate in the neighborhood of Florida when a cold north wind has swept under the warm moist air of the gulf and ocean. Another class originates in a similar manner in the western portion of the gulf of Mexico after a Texas norther has prevailed for a few days. A few begin in the interior of Texas when a high barometric pressure on the gulf, or a low pressure in the western territories, forces or draws the air of the gulf up over the plains of Texas. But by far the larger class of the Atlantic hurricanes, including those of greatest extent and violence, appear to originate between the Windward islands and the African coast, and generally quite near to the latter; apparently these begin with heavy rains in the region of calms, such as are accompanied on the African mainland by the peculiar harmattan and tornadoes of that coast, which may be, so far as we know, either the consequence or the determining cause of the heavy rains. The storms that originate here may either move as far west as the American coast before recurving toward Iceland and Norway, or may describe a much shorter route, and

finally arrive at Great Britain, or possibly at Portugal.—*Rules for the Avoidance of Hurricanes at Sea.* The researches of Redfield first led to the suggestion of certain rules for the direction of navigators. The erroneous theories of the purely circular and of the radial movement of the hurricane winds early led their respective advocates to the suggestion of rules for avoiding the dangers of these storms, which later and more correct views as to the spiral or vorticose movement have somewhat modified. It may in general be said that a vessel's safety can only be assured by the possession of a reliable barometer, either aneroid or mercurial; and having this, the navigator should proceed thus: First, as soon as the ocean swell, the falling barometer, the clouds, and the rain announce that a hurricane exists, though it may be 500 m. from him, he should at once lay to long enough to ascertain how rapidly the barometer is falling and the wind increasing, and in which direction the course of the wind is changing. If the wind increases without materially changing its direction, the storm centre is advancing directly toward him; if, however, the wind veers or backs, the direction in which the centre is at any moment may be approximately determined by the rule above given, viz.: "in the northern or southern hemisphere, stand with your back to the wind, and the centre will be on your left or right hand, and in front." The mariner may then by due consideration of his own desired course, and the customary track of hurricanes in that part of the ocean, so alter his course as to avoid the storm centre on the one hand and a lee shore on the other, and may indeed, if there be plenty of sea room, take advantage of the strong wind to hasten his own course. Further details on this subject are given in all works on navigation. It is very rare that a navigator cannot by cautious manœuvring thus avoid the dangerous portions of a hurricane; on the other hand, it is said that many ocean steamers, relying upon the power of their engines, the strength of their build, and their great speed, deliberately plough through the heart of the severest storms rather than incur a possible delay of a few hours in order to avoid them. The hurricane of August, 1873, which destroyed over 1,000 vessels on our Atlantic coast, and those of October, 1873, and February, 1874, afforded numerous instances of such bravado.

HURST, John Fletcher, an American clergyman, born near Salem, Md., Aug. 17, 1834. He graduated at Dickinson college in 1853, taught ancient languages two years at Ashland, N. Y., went to Germany and studied theology at Halle and Heidelberg, returned to the United States in 1858, and for eight years was pastor of Methodist Episcopal churches, chiefly in Passaic and Elizabeth, N. J. In the autumn of 1866 he took charge of the theological department of the mission institute of the German Methodist church in Bremen, Germany, which

was afterward removed to Frankfort under the name of the Martin mission institute, where he continued to be its director for three years, meantime visiting Russia, the Scandinavian countries, France, Switzerland, Italy, Great Britain, Greece, Syria, and Egypt. In 1871 he returned to the United States to become professor of historical theology in the Drew theological seminary at Madison, N. J. In 1873 he was elected president of that institution, retaining his chair of historical theology. Dr. Hurst has published a "History of Rationalism" (1865), "Outlines of Bible History" (1873), "Martyrs to the Tract Cause" (1873), and "Life in the Fatherland: the Story of a Five Years' Residence in Germany" (1874). He has translated portions of Hagenbach's "History of the Church in the 18th and 19th Centuries" (2 vols., 1869), Van Oosterzee's "Lectures in Defence of St. John's Gospel" (1869), and Lange's "Commentary on the Epistle to the Romans," with additions (1870).

HURTER, Friedrich Emanuel von, a Swiss historian, born in Schaffhausen, March 19, 1787, died in Gratz, Aug. 27, 1865. He studied theology at Göttingen, and was gradually promoted to high ecclesiastical offices; but he was opposed on account of his high-church views, and his *Geschichte Papst Innocenz III. und seiner Zeitgenossen* (4 vols., Hamburg, 1834-'42) resulted in 1841 in his withdrawal from the church over which he presided in Schaffhausen, and he joined the church of Rome in 1844. In 1846 he was appointed historiographer of the emperor of Austria, who ennobled him. Among his later publications is *Geschichte des Kaisers Ferdinand II. und seiner Aeltern* (11 vols., Schaffhausen, 1850-'64).

HUSBAND AND WIFE. The laws which govern the marital relation, and determine the mutual rights and obligations of the parties, are among the most important of all laws; and it is to be regretted that in the United States they are less accurately determined and less ascertainable than any others of equal consequence. The reason is that we received from England this portion of the common law, and have only of late years perceived its repugnance to reason and justice. We now know that the feudal system, upon which the common law is founded, did not give to woman that place and those rights which she ought to have. It not only regarded husband and wife as one, but the husband as that one. The sentiment that the law needs vast change in this respect is proved to be universal by the fact that there is no one of our states in which it has not undergone great modification; and the difficulty in making the change in such a way that the essential character of the marriage relation may not be impaired, is proved by the great diversity in the provisions recently introduced, in the frequent changes among them, and in the very frequent expression of opinion that much harm has already been done. In the East woman has always been regarded as

a servant of her husband, as his property, and as his plaything; and man has always been held in absolute political subjection. In Greece there were republics and democracies, in name at least; and certainly that political tyranny which had prevailed among eastern nations was greatly lessened, and the domestic tyranny of the husband over the wife was modified about equally. But the liberty of Greece was the liberty of comparatively few, who were masters of the many; and the most conspicuous of the women of Greece were those who, like Sappho and Aspasia, had indeed escaped from the *gynæceum*, but had not found a home. In Rome there was a wider spread and better protection of personal right, for even under the most despotic emperors municipal rights and privileges were generally preserved throughout the Roman world; and woman had also advanced so far, that the Roman matron has been since regarded as the type of female dignity and purity. But much was yet wanted. The feudal system, built upon the ruins of western Rome by the Teutonic nations, a new race, acknowledging the new influence of Christianity, made an immense advance, because it gave to every man, even the serf, a definite place and definite rights, and in theory at least knew nothing of unlimited power; and to woman it gave the unspeakable advantage of Christian marriage. It introduced, probably as a means of remedying or of mitigating social mischiefs which it could not otherwise restrain, the spirit of chivalry, whose controlling principle was the sentiment of honor; and while this newly developed sentiment exerted a very wide and beneficial influence upon all the relations and all the departments of society, in nothing was it more useful than in the profound respect and tender care which it sought at least to inspire toward woman. It was under this feudal system that the law grew up which forms the basis of the law under which we live. It was by the gradual elevation of woman in social and domestic life, by the side of man as he rose toward the possession of political rights, that so much good was attained as exists in that law. That the law of husband and wife in the United States is in advance of any that has existed or now exists elsewhere, we are confident. The tendency of the law, however incomplete it may yet be, is to respect and secure the rights of woman in such wise as to preserve her influence and her happiness; and to make the relation of husband and wife not a form of servitude or the means of oppression, but the central origin of blessings which could spring from no other source, and may pervade the whole life of both sexes. As much the greater part of the common law is still in force with us, and whatever laws we have are but various modifications of that law, we purpose, first, to give a condensed view of the principles of the common law in its reference to the relation of husband and wife; and then to present a brief statement of

the principal variations from this law in all the states of this Union. Promises to marry, the contract of marriage, and settlements or contracts in view of marriage, will be considered in the article MARRIAGE. Here we shall treat only of the effect of marriage on the property of a woman, and of the husband's liability for her debts contracted previous to marriage, and of her power to bind him by her contracts, and of his obligations for her, after marriage.—1. A woman's real estate remains her own after marriage; but her husband acquires a right to it (or, in law language, an estate in it) for her life, and an estate in it for his own life as soon as a living child is born to them, by what is called tenancy by curtesy. He has therefore a life estate in her land either for her life or for his own life; but when this life estate ceases, her rights, or the rights of her heirs, revive absolutely. He cannot transfer her land by his deed, nor can she by her deed; but in this country it may be transferred by the joint deed of the two. In different states different precautions are provided by law, to make it sure that she executes such a deed of her own free will. Thus, in many of the states, she must be examined apart from her husband, by some magistrate, as to her willingness and her motives for thus disposing of her land. On the other hand, by her marriage, she acquires an indefeasible right of dower to the use of one third of his lands during her own life, of which she cannot be divested but by her own act. In this country she usually releases her right of dower, when she wishes to do so, by adding her release to her husband's deed of the premises; but his creditors cannot generally get it in any way without her consent. (See DOWER.) 2. A woman's personal property in possession becomes absolutely the husband's property by marriage. By this is meant all the money in her hands, and all her chattels, as furniture, plate, pictures, books, jewels, &c. Nor can he by common law give to her either of these or chattels of his own during marriage, because transfer of possession is essential to a valid transfer by gift, and her possession is his possession in law. He however may give to her by his will what he chooses to, and may doubtless make a valid transfer of anything in possession as a gift *causa mortis*. (See GIFT.) The reason why the personal property of the wife is thus absolutely transferred to the husband may have been, in part, the lingering influence of the falsity which regarded the wife herself as only the property of the husband; but it was much more, probably, the comparative worthlessness of personal possessions in the feudal ages, when the common law began. Whatever were the reasons, they have little force or application at present. A single woman may, in general, make whatever contracts a man can. If by such a contract she acquires and receives into her own hands any property, it is property in possession, of which we have spo-

ken. But if the thing which she purposes to obtain by the contract be money, or the right to dividends, or any other right, and it remains to be received or acquired after her marriage, she herself possesses not the thing, but a right to demand and receive the thing; and this right is a thing in action (usually called by the Norman French phrase a *chose in action*), and not a thing in possession. This chose in action, belonging to the wife, passes by marriage to the husband, but not absolutely. What he acquires is the right to reduce it to possession, and thereby make it absolutely his own. But he is not obliged to reduce it to possession; and if he does not, and dies, the wife surviving him, all his right is gone, and the chose in action remains as absolutely the property of the widow as it would have been had she never married. The principal choses in action to which this rule applies are notes, bills of exchange, and evidences of debt generally, and scrip or stocks standing in her name. The principal ways of reducing it to his possession are four: by collecting and receiving the debt for his own use; making a new contract with the debtor in his own name, in substitution for her name; having the scrip or certificates or other evidences of debt transferred to himself and his own name; or suing the debt and recovering a judgment upon it. If she dies before him, and before he has reduced them to his own possession, he may now do so as her administrator, and then retain them for his own benefit. If he dies (having survived her) without having reduced them to possession, his next of kin may take out letters as her administrator, and reduce the choses in action to possession for his heirs. In regard to the debts she owes at the time of marriage, the general rule is that the husband is answerable for all of these. The creditor may demand payment of the husband, and may sue him. This is equally true of the debts which had matured and become due before marriage, and of those which were not payable until afterward; and his liability for her debts is the same, whether he receives much with her, or little, or nothing. But this liability is not absolute; for if she dies before he pays the debt, and before a judgment is recovered against him, his liability ceases. But if she leaves choses in action not reduced to the husband's possession, these are still liable for her debts, and the husband, or whoever becomes her administrator, must apply them to pay these debts, and retain only the surplus for the husband or his next of kin. If he dies before he pays her debts, and before judgment is rendered against him, his estate is not liable, but the wife's liability, which was suspended during his life, revives at his death. This is true although he received a large property with her. But when a wife thus brings a considerable property to her husband, courts of equity sometimes interfere on her application and compel him and his assignees to make an equitable settlement out of it for the

support of herself and of the children of the marriage, if any. 3. We will now consider the contracts or obligations of the wife made or entered into during marriage. In the first place, a married woman has at common law no power whatever to make a valid contract which shall bind herself or her husband. If money is due for her services, or for money lent by her, it is due not to her, but to him. Her time and her labor and her money are all his. But she may act as his agent in making a contract, and if authorized by him, he is bound. This authority may be express, or it may be implied from frequent acts of agency recognized by him, as when she acts as his clerk, accepting or paying bills, &c.; and then it does not differ in law from a common agency. There is, however, an important and peculiar agency of the wife, growing out of her duties; and this is an implied agency for the husband in all domestic matters, as the hiring of servants, and the purchase of provisions and of clothing for the family. As this grows out of necessity, it is measured by it; but the law means a reasonable necessity, and this is only an appropriateness. For any contract of this sort made by her, which is in due conformity with her husband's means, station, and manner of life, would bind him, and he would not be permitted to deny his authority. If they exceeded this necessity or appropriateness, the husband could be held only on some evidence of authority or assent, as that he knew the contract, or saw the things bought, and made no objection. The question then occurs, How far is the husband bound to supply the necessities of the wife? The general rule on this subject is, that he is bound to supply her with all necessaries, which means in this case all her reasonable wants, while they live together. If they separate because he drives her away without sufficient cause, the same liability continues; and then he is responsible for any debts she may contract for this purpose. Even Lord Eldon declared that "where a man turns his wife out of doors, he sends with her credit for her reasonable expenses." (3 Espinasse, 250.) There can hardly be a sufficient cause for thus casting her off without his liability for her subsistence, unless it be her adultery; but this certainly is sufficient. If, however, she voluntarily leaves him, she cannot carry his credit with her, unless she leaves with sufficient cause; and while it is not easy to determine in all cases what would be sufficient cause, perhaps it would be safe to say that any cause which would be sufficient for divorce, either from the bonds of matrimony or from bed and board, would justify her leaving. While the law is now pretty well settled, both in England and in this country, as to when the husband is liable for necessaries furnished to the wife, and when he is not, a question of much moment remains, and of late years has been much considered, viz.: On what ground does this liability rest? It must rest on his authority as proved, or as im-

plied by law; or else upon his marital duty as husband. If it stands upon the former foundation, it must follow that he may always prevent his liability by express refusal and prohibition; or, in other words, that he always has the power to limit or prevent his liability. If it stands on the foundation of his marital duty, this he is bound to discharge, and his prohibitions are of no effect. The former was the unquestionable rule in England and here until very recently, no other ground for the husband's liability being recognized in any way than his authority express or implied; and therefore it was held that if a wife lived with her husband, no one could recover from him the price of any necessaries supplied to her, under any circumstances, against his prohibition. Thus, Chief Justice Hale said (1 Siderfin, 109): "The law will not presume so much ill, as that a husband should not provide for his wife's necessities." At length, however, it began to be seen that there might be cases of incapacity, as where the husband was wholly insane, and could not be supposed to constitute an agent or confer authority upon any one; and yet it could not be supposed that the wife was to be deprived of the necessaries of life which her husband's means were amply sufficient for, because he could not authorize the purchase of them. Again, we have seen that the husband who drives his wife abroad sends his credit with her; but the absurdity of supposing that he constitutes her his agent struck the court. Baron Alderson said (*Read v. Legard*, 6 Exch., 636): "It is a monstrous proposition that a man who drives a woman out of doors, who hates, who abominates her, actually gives her authority to make contracts for him." In that case the principle was recognized that the right of a wife to a proper support grows out of the marital relation, and that the liability of the husband for necessaries supplied to her is a consequence of that right. This case was so decided in 1851; but like decisions had previously been made in this country, and are now the settled law. It must be remembered, however, that there is an essential difference between the case where husband and wife cohabit, and that where they live apart. In the first, the presumption of law is strong against the husband; and he can resist payment for supplies furnished only by showing that they were not necessaries, either because they were unreasonable and inappropriate in kind or in amount, or that the wife was sufficiently supplied elsewhere. But if she have separated from him, no such presumption exists. Whoever supplies the wife now, takes upon himself the risk of being able to show that she needed what he gave her, and that there was no such sufficient cause for the husband's withdrawing his support of her as would destroy his liability for what was furnished to her.—As to the separation of husband and wife by mutual consent, the law has always regarded it as a kind of voluntary divorce, and formerly refused to

admit or acknowledge it in any way. Of late years, however, it seems to be otherwise. It is still a rule of the common law that husband and wife cannot contract with each other, because they are not two persons, but one. Hence no bargain which they can make directly with each other has any force or effect at law. But if they make their bargain through and by means of a third person, by way of trustee, and enter into certain covenants with him, a court of equity, and for some purposes a court of law, would permit this trustee to maintain such actions as might be necessary to give full effect to the bargain, although its only purpose were to provide for the separation of the parties. There are, however, two qualifications to this rule. One is, that if the court see that the terms of separation are catching, oppressive, or unreasonable, they will not carry them into effect. The other is, that the *locus penitentia* is always kept open. Although the bargain provides that the separation shall be perpetual, and all its terms are founded upon this supposition, and are clothed for this purpose in the most stringent language, yet, as soon as either party wishes the separation to cease, it must cease. The husband cannot deprive himself of his right to recall his wife; and she cannot deprive herself of her right to return. By the "custom of London," a married woman may be a sole trader there, but nowhere else in England. In the United States, partly by statute and partly by adjudication, a married woman would generally be permitted to carry on business on her own account, much as a single woman might, in case of continued abandonment, or long imprisonment of the husband, or alienage and non-residence, or with the knowledge and consent of the husband, which might be inferred from circumstances. It should be added that the husband is liable for the wife's wrong doings in many cases; as for her libel, slander, fraud, cheating, and generally for injurious misconduct. If she commit a crime in his presence, the law presumes that he ordered it; but he may remove this presumption by evidence of its falsity.—Important changes have been made in the common law by statutes in the several states of the American Union. In Maine, the property owned by the woman at marriage or acquired afterward remains hers, and she has the same rights as any other owner in respect to it, except that if the property came from the husband she cannot dispose of it without his joining. In New Hampshire, after three months' desertion or any act of the husband entitling her to divorce, she may hold and dispose of the property by her acquired and the earnings of the minor children, and the judge of probate may order provision made for her from her husband's property in the state, and her property shall descend on her death as if she were single. A married woman may will her property to any one except her husband, but not cut off his right by the curtesy. In Vermont, the su-

preme court may authorize a deserted wife to convey her estate and the personal estate which came to the husband by the marriage, and require the debtors of the husband in her right to make payment to her; and the proceeds of the earnings of herself and the minor children are to be at her disposal. The rents and profits of the wife's real estate, and the interest of the husband in it, are exempt from execution for his debts, and can only be conveyed by her joining in the deed. The wife may dispose of her property by will. In Massachusetts, a married woman may be a sole trader, and may dispose of her real estate by will, leaving to the husband his estate by the curtesy, and also her personal estate, but not more than one half of it away from the husband without his consent. She holds as her own all property howsoever acquired except by gift from her husband, but she cannot convey real estate or shares in a corporation except with his consent, or the consent of a judge of the supreme, common pleas, or probate court. Her real estate and corporate shares are not liable for the husband's debts. In Rhode Island, a married woman may dispose of her real estate by will, saving to the husband his estate by the curtesy, and whatever deposits are made by her in savings banks are her own. In Connecticut, the personal property acquired by the husband in right of the wife he holds as trustee for her, except to the extent he may have paid ante-nuptial debts, and his interest in her real estate cannot be taken for his debts during her life or the life of children. The proceeds of her real estate are deemed hers in equity and not subject to his debts, and all acquired by her personal services is hers absolutely. Her savings deposits are also her own, and there are further provisions in case of abandonment or abuse by the husband. In New York, the wife's property, acquired before or after marriage, is subject to her own control, and not liable for the husband's debts, but is liable for her own debts, while the husband is not liable except in case of neglect to take out administration on her estate on her death. In New Jersey, the real and personal estate of the wife, whenever acquired, remains hers, free from her husband's control and not liable for his debts. In case of his desertion she may have provision made for her from his estate. In Pennsylvania, the property of the married woman, acquired before or after marriage, remains hers, free from any control by the husband, and liable for her debts, but not for his. The husband is not liable for the wife's ante-nuptial debts. In case of desertion or neglect by the husband to provide for her, she has the rights of a *feme sole*. In North Carolina, the interest of the husband in the real estate of the wife cannot be taken on execution for his debts, nor can it be disposed of by the husband except with her consent. In Florida, the property of the wife remains hers, and the husband is not liable for her

ante-nuptial debts. The same is true in Alabama, and substantially so in Mississippi. In Louisiana the laws are peculiar, but it is competent for the married woman to carry on business as a sole trader, and to have all her property secured to her own use, or the property of the two may be in common. In Texas the laws are also peculiar, but the property of the wife owned at the marriage, or acquired by gift, devise, or descent afterward, remains her own, though subject to the husband's management. In California, the property owned by either the husband or wife at the time of the marriage remains his or hers, as does also any that either may acquire by gift, bequest, devise, or descent afterward, with the rents, issues, and profits thereof; but all other property acquired by either afterward is community property. Husband and wife may contract with each other or with third persons respecting property, as they might if unmarried; his separate property is not liable for her ante-nuptial debts, nor her separate property or earnings for his debts, and dower and curtesy are abolished. While the husband is liable for the wife's support, the wife is also liable for his support if he has no separate property and they have no community property, and he from infirmity is incompetent to support himself. The husband has the management of community property, and may dispose of it otherwise than by will. In Kentucky, a married woman may dispose of her separate property by will, and the husband during her lifetime has only the use of it. In Ohio, a married woman may dispose of her separate property by will, and the interest of the husband in any of her property cannot be taken for his debts during her life or the life of children. In Indiana, the wife's property remains hers and may be disposed of by will, and is not liable for the husband's debts. In the other western states, it may be said generally, the real and personal estate owned by the wife before marriage or acquired by her afterward is at her absolute disposal, by contract, conveyance, or will, and not subject to her husband's debts; while the husband is not liable for her debts contracted before marriage nor for those contracted afterward, except where she may have acted as his agent and with the proper authority. The recent changes in the southern states have been in the same direction. It is not easy to say exactly how the estate by the curtesy stands in the states where it is not expressly saved by statute, but we should say any valid conveyance of the wife's estate would cut it off, and in some states it has been decided that the broad terms in which statutes secure to married women their property will preclude curtesy attaching.—In other respects statutes have made important changes respecting the rights of women which do not depend on the status of marriage. Thus, in the territory of Wyoming the distinction of sex in the exercise of the elective franchise has been abol-

ished, and women of the requisite age are admitted to vote and are eligible to office. In Illinois, by statute, women passing the necessary examination may be admitted to the bar, and in some of the other states they have been admitted by the courts without question. Women who pay school taxes are voters at school meetings in a number of the states, and in recent elections in some, notably in Illinois and Iowa, women have been chosen county superintendents of schools. In Michigan a woman has for several years been state librarian.

HUSBANDRY, Patrons of, an organization of agriculturists in the United States. Its origin is attributed to Mr. O. H. Kelley, a native of Boston, who in 1866, being then connected with the department of agriculture in Washington, was commissioned by President Johnson to travel through the southern states and report upon their agricultural and mineral resources. He found agriculture in a state of great depression consequent upon the radical changes wrought by the civil war and the abolition of slavery. At the same time there was much dissatisfaction among the farmers of the west and northwest in consequence of the alleged high charges and unjust discriminations made by railroad companies in the transportation of their products. The farmers also complained of the exorbitant prices exacted by middlemen for agricultural implements and stores. Mr. Kelley conceived the idea that a system of coöperation, or an association having some resemblance to the order of odd fellows or masons, might be formed with advantage among the dissatisfied agriculturists. For this purpose a plan of organization was determined upon by him and Mr. William Saunders, of the department of agriculture. The name chosen for the order was "Patrons of Husbandry," and its branches were to be called granges (Fr. *grange*, a barn). The constitution of the order provides for a national grange and state and subordinate granges. There are ceremonies of initiation, rituals, and injunctions of secrecy, though in some respects the order is not secret. The officers of a grange, whether national, state, or subordinate, are elected by the members, and comprise a master, overseer, lecturer, steward, assistant steward, chaplain, treasurer, secretary, gate keeper, Ceres, Pomona, Flora, and lady assistant steward. Women are admitted to membership upon the same terms and with equal privileges as men, but only those persons interested in agricultural pursuits are eligible. Regular meetings of the national and state granges are held annually, while subordinate granges usually meet monthly or oftener. The constitution was adopted, and on Dec. 4, 1867, the national grange was organized in Washington; its headquarters are now in Georgetown, D. C. In the spring of 1868 Mr. Kelley founded a grange in Harrisburg, Pa., one in Fredonia, N. Y., one in Columbus, O., one in Chicago, Ill., and six in Minnesota. The number of granges soon began

to multiply rapidly, and in 1874 they had been organized in nearly every state and territory of the Union. In 1871, 125 granges were established; in 1872, 1,160; in 1873, 8,667; and in the first two months of 1874, 4,618. At the beginning of 1874, the number of granges in the United States was 10,015, with a membership of 750,125. The total number of members in April, 1874, was estimated at about 1,500,000. The order has its greatest strength in the northwestern and western states, and is well represented in the south. At the annual meeting of the national grange in St. Louis, Mo., in February, 1874, a declaration was adopted setting forth the purposes of the organization as follows: "To develop a better and higher manhood and womanhood among ourselves; to enhance the comforts and attractions of our homes, and strengthen our attachment to our pursuits; to foster mutual understanding and coöperation; to maintain inviolate our laws, and to emulate each other in labor; to hasten the good time coming; to reduce our expenses, both individual and corporate; to buy less and produce more, in order to make our farms self-sustaining; to diversify our crops, and crop no more than we can cultivate; to condense the weight of our exports, selling less in the bushel, and more on hoof and in fleece; to systematize our work, and calculate intelligently on probabilities; to discountenance the credit system, the mortgage system, the fashion system, and every other system tending to prodigality and bankruptcy. We propose meeting together, talking together, working together, buying together, selling together, and in general acting together for our mutual protection and advancement as occasion may require. We shall avoid litigation as much as possible by arbitration in the grange. We shall constantly strive to secure entire harmony, good will, vital brotherhood among ourselves, and to make our order perpetual. We shall earnestly endeavor to suppress personal, local, sectional, and national prejudices, all unhealthy rivalry, all selfish ambition. Faithful adherence to these principles will insure our mental, moral, social, and material advancement." One of the chief aims of the organization is to bring producers and consumers, farmers and manufacturers, into direct and friendly relations; for this purpose coöperation is encouraged among farmers in the purchase of agricultural implements and other necessities direct from the manufacturer. The organization therefore is maintained for social and economic purposes, and no grange can assume any political or sectarian functions.

HUSBANDS, Herman, an American revolutionist, born in Pennsylvania, died near Philadelphia about 1794. Removing to Orange co., N. C., he became a member of the legislature and leader of the "regulators," a party which was organized in 1768 for the forcible redress of public grievances. He published in 1770 a full account of the rise of the troubles. A

battle took place in 1771 between Gov. Tryon with 1,100 men and 2,000 of the insurgents on the banks of the Alamance, in which the latter were defeated. Husbands escaped to Pennsylvania, where he was concerned in the whiskey insurrection in 1794, and was associated with Albert Gallatin, Breckenridge, and others, as a committee of safety.

HUSH, a town of Roumania, in Moldavia, near the Pruth, 36 m. S. E. of Jassy; pop. about 13,000. It is the seat of a Greek bishop, and has a normal school. Here, on July 25, 1711, the peace was concluded between Russia and Turkey which saved Peter the Great and his army on the Pruth from destruction or captivity.

HUSKISSON, William, an English statesman, born at Birch-Moreton, Worcestershire, March 11, 1770, died at Eccles, Lancashire, Sept. 15, 1830. He was originally intended for the medical profession, and in his 14th year went to Paris to pursue his studies. Here he resided for several years, and adopted the revolutionary doctrines of the day; but he afterward abandoned them, and became private secretary to the British ambassador, Lord Gower, with whom he returned to England in 1792, and in 1795 was made under secretary of state for war and the colonies. In 1796 he entered parliament, of which, with the exception of two years, from 1802 to 1804, he remained a member until his death. Following the fortunes of Mr. Pitt, he retired from office with him in 1801, and became secretary of the treasury on the formation of the new Pitt ministry in 1804. He attached himself to Mr. Canning, taking office with him in 1807 and retiring in 1809. In 1814 he was appointed chief commissioner of woods and forests, and in 1823 entered the cabinet as president of the board of trade and treasurer of the navy, which offices he retained until the death of Canning. In the Goderich cabinet and in that of the duke of Wellington he held the office of secretary for the colonies till May, 1829, when the redemption of a pledge formerly given obliged him to vote against his colleagues, and he resigned. As a public man he was chiefly known by his speeches on financial and commercial subjects; and he is regarded as the great pioneer in the free-trade movement. In 1823 he carried through parliament an act for removing various restrictions upon commerce. He was also active in procuring the repeal of the combination laws and the relaxation of the restrictions on the exportation of machinery. He was present at the opening of the Liverpool and Manchester railway, and at Parkside, while conversing with the duke of Wellington, was run over by a locomotive, and died the same evening.

HUSS, John, a Bohemian religious reformer, born about 1373, burned at Constance, July 6, 1415. His surname was derived from his place of birth, Hussinetz, near the border of Bavaria. He studied first in his own town,

then in Prachatitz, and finally at the university of Prague, where he graduated in 1393. In 1398 he began to give lectures in philosophy and theology; in 1401 he became president of the university faculty of theology; and in 1402 he was installed preacher in the Bethlehem chapel, which had been established ten years earlier for the purpose of enabling the people to hear preaching and the Scriptures in the Bohemian tongue. He became the confessor of the queen, and the head of a party of priests and scholars who meditated reforms in discipline and in doctrine. His first polemical treatise, *De Sanguine Christi Glorificato*, was occasioned by the pilgrimages to Wilsnack to see and worship the miraculous blood of Christ there shown on the consecrated host. In successive sermons preached before the archbishop, Huss next arraigned the misconduct of the clergy even in high places; demanded the despoiling of the churches of useless ornaments, that the poor might be fed and clothed; and called upon the secular officers to hinder and punish the open vices of ecclesiastics. This excited strong opposition, which was increased when the ordinance of Charles IV., giving special privileges to the native over the foreign students, was revived by Huss, and the Poles and Germans deserted the university, depriving the city of thousands of its population. Soon afterward he became rector of the university. Other circumstances, connected with the papal schism, aided to embroil Huss with the archbishop and his friends. It became a warfare between the university and the cathedral. The pope interfered for the latter; and, fortified by his bull, at the close of the year 1409 the archbishop Sbinko burned 200 volumes of the works of Wycliffe, which had been deposited in his palace. Against this act Huss protested, in a spirited treatise addressed to the new pope, John XXIII., with arguments of such weight that a commission of doctors condemned the archbishop for irregular action. The cry of heresy was now raised against Huss, and he was summoned to Rome to answer this charge. The court, the university, and even the archbishop sent a defence of his orthodoxy, and Huss sent advocates to plead his cause before the cardinals, but they were not heard. He was condemned as a heretic, and ordered to quit Prague; and the city was placed under ban so long as he should remain there. Finding it vain to resist, he left the city; but his retirement only inflamed the zeal of his partisans. The books which he wrote at this period, half apologetic, half polemic, tended more and more to widen the breach and to arouse acts of violence. An outbreak in the city followed; the partisans of Huss were victorious, the archbishop fled, and Huss came back to his chapel, emboldened to preach more and more vehemently against prevalent corruptions. He praised the king for upholding the cause of truth and purity against the mandates of eccle-

siastical power; and in his treatise *Contra Occultum Adversarium*, written at this time, he maintains the doctrine that kings have the right to rule the clergy not less than the laity. Soon more serious trouble arose. The pope had issued bulls of excommunication against King Ladislas of Naples. Political reasons induced the court and university to side with the pope; but Huss immediately published two tracts against the papal bulls. A reaction followed. The partisans of the pope were insulted in the streets, and Huss had great difficulty in restraining the fury of his followers. This was followed by tracts which maintained that the clergy were only stewards of the wealth in their possession, which belonged to the people and not to the church. Huss contended that not the priest's word, but the power of God, wrought the change of transubstantiation; claimed that any one moved by the Spirit had the right to preach; and asserted the right of conscience as against the edicts of popes and councils. He was accused of denouncing the veneration of saints and the worship of the Virgin, but defended himself against these charges. He was again summoned to Rome, but took no heed of the order. Repeated attempts were made by the king to compose the difficulties, but without success. A decree was procured from Rome, putting Huss again under ban as an incorrigible heretic; and at the earnest request of the king, he left Prague for a time, and found shelter in his native town. In a long treatise upon "The Church," he holds that the papacy began to exist at the time of Constantine, and that its usurpations threatened to secularize and so to destroy the gospel. Frequent letters and occasional secret visits confirmed the zeal of his partisans. He continued to preach in the cities to immense crowds; and after a time, to be nearer Prague, he removed his residence to the castle of Cracowitz, which had been offered him as a refuge. In 1414, at the instigation of the emperor Sigismund, Pope John XXIII. summoned a general council at Constance, and Huss was cited to appear. Trusting to the safe-conduct which the emperor granted him, he resolved to obey. On his arrival at Constance he was welcomed by the pope with a fraternal greeting, and was promised that the former interdict should be suspended. For some time Huss was free to come and go, to discuss and preach. Expecting a special trial, he had prepared his defence. But on Nov. 28 he was arrested and imprisoned in the cathedral, and several days later transferred to the Dominican convent, on an island in the lake. An accusation against Huss had been drawn up, and three commissioners were appointed to visit him in prison, question him, take down his answers, and report to a council of doctors. Huss asked, but was not allowed, the assistance of counsel. His private letters were opened, his appeals to the emperor disregarded, and the kind treatment of his prison keepers could hardly compensate for the in-

justice of his enemies. The flight of the pope only aggravated his suffering. He was transferred to the strong castle of Gottleben, heavily chained. A new commission was appointed to examine and decide in his affair, and at the beginning of June, 1415, he was removed to the Franciscan convent in Constance. On June 5 he had his first hearing before the council, which had already at a previous session condemned the heresy of Wycliffe. The attempt of Huss to answer the first article of accusation was met by such a storm of outcries that he was unable to proceed; and the hearing was adjourned until the 7th, when it was renewed in presence of the emperor. He was accused of denying transubstantiation; of treating St. Gregory as a buffoon; of teaching the doctrines of Wycliffe; of encouraging his friends to resist the mandates of the archbishop; of exciting a schism of the state from the church; of appealing from the pope to Christ; of counselling the people to violent and aggressive measures; and of boasting that he could not have been forced either by pope or emperor to come to Constance, unless he had chosen to come. Some of these charges he admitted; some he denied. A third hearing was allowed him on the next day, when 39 articles, extracted from three of his works, were read, touching various points of his teaching concerning the church, its officers and sacraments. Huss was then summoned to retract these heresies, which he declined to do, affirming that he could not retract what he had never said, nor ought he to retract what he had said until its falsity was shown. On June 24 the books of Huss were condemned to be burned as heretical, and on July 6 he was brought before the council to receive sentence. After a discourse by the bishop of Lodi, from the text, "that the body of sin be destroyed," the 39 articles were read, together with the sentence of condemnation of the books of Huss, and finally the sentence of himself, to be degraded from the priesthood as an incorrigible heretic, and given over to the secular arm. He was then conducted out of the city to an open field, in which a stake and a pile of wood had been erected. Here he was again summoned to abjure his heresies, but at the summons he only knelt and prayed, using the words of the psalms of David. As the fire was kindled, he began to sing with a loud voice the *Christe eleison*, and only ceased when he was suffocated by the rising flame. The ashes of the pile were gathered and cast into the Rhine; all traces of the event were carefully obliterated, and to this day the exact spot remains uncertain.—The writings of Huss, not including the minor pieces lately published by Palacky, are of four kinds, dogmatic and controversial, exegetical, sermons, and epistles. Of the first class, there are 27 separate treatises, besides fragments. Of the class of exegetical writings, there are five treatises, on the acts of Christ, the passion of Christ, a commentary on seven

chapters of the first epistle to the Corinthians, notes on other canonical epistles, and an explanation of ten of the Psalms. In the class of sermons there are 38, two of which were written at Constance, but never preached. There are two series of letters, the first of 14, written before, and the second of 56, written after his departure from Prague to Constance. The complete works of Huss were published in quarto at Strasburg in 1525. For his biography, see Neander's "Church History" (vol. v., Torrey's translation), Gillett's "Life and Times of Huss" (2 vols., Boston, 1863), and Palacky's *Documenta Magistri Joannis Vitam, Doctrinam, etc., illustrantia* (Prague, 1869). (See HUSSITES.)

HUSSARS (Hung. *hús*, 20, and *ár*, rate), the national cavalry of Hungary and Croatia. The name is also applied to some bodies of light cavalry in the armies of other countries of Europe. It is derived from the fact that in the 15th century every 20 houses in Hungary were required to furnish a soldier with a horse and furniture. The arms of the hussars are a sabre, a carbine, and pistols. Their regimentals were originally a fur cap with a feather, a doublet, a pair of breeches to which the stockings were attached, and a pair of red or yellow boots. There were five regiments of hussars under Tilly at Leipsic in 1631. The name first became general in the 18th century, when regiments of hussars were organized in the principal European armies.

HUSSITES, the name of the followers of John Huss in Bohemia, who, on his death in 1415, organized as a sect, making the offering of the cup to the laity in the sacrament of the eucharist the badge of their covenant. Upon the death of Wenceslas (1419) they refused to recognize the emperor Sigismund as king, whereupon the Hussite civil war broke out. They were divided into two parties, the more moderate Calixtines and the more rigid Taborites. Ziska, the leader of the latter party, assembled them on a mountain which he fortified and called Mt. Tabor, captured Prague, pillaged the monasteries, and in several engagements defeated Sigismund. (See ZISKA.) After the death of Ziska (1424) his place was filled by a monk named Procopius, who defeated the mercenaries sent under the name of crusaders by the emperor and the papal legates in the battles of Mies (1427) and Tachau (1431), and whose troops ravaged Austria, Franconia, Saxony, Catholic Bohemia, Lusatia, and Silesia. A council held at Basel in 1433 made concessions which were accepted by the Calixtines. (See PROCOPIUS.) The Taborites, rejecting the compromise, were vanquished near Bohemian Brod (1434), and by the treaty of Iglau (1436) the compromise of Basel was accepted by Bohemia, and Sigismund was recognized as king. On the death of Sigismund (1437) controversies again arose, and civil wars were prosecuted with no decisive results, till at the diet of Kuttenberg (1485) a peace was established

by King Ladislas which secured Catholics and Calixtines in the possessions they then held.— See Schubert, *Geschichte des Hussitenkriegs* (1825); Grünhagen, *Geschichtsquellen der Hussitenkriege* (1871); Bezold, *König Sigmund und die Reichskriege gegen die Hussiten* (1872); and Palacky, *Urkundliche Beiträge zur Geschichte des Hussitenkriegs* (1872).

HUTCHESON, Francis, a Scottish philosopher, born in Ireland, Aug. 8, 1694, died in Glasgow in 1747. He studied theology at Glasgow, and became pastor of a Presbyterian congregation in Ulster. His "Inquiry into the Original of our Ideas of Beauty and Virtue" (1720) gave him distinction among philosophers. In 1728 he published a treatise on the "Nature and Conduct of the Passions and Affections," and in the following year was appointed professor of moral philosophy in the university of Glasgow. His *Synopsis Metaphysicæ Ontologiam et Pneumatologiam complectens*, and his *Philosophiæ Moralæ Institutio*, were written as text books for his classes. His most complete and elaborate work, the "System of Moral Philosophy," appeared after his death (2 vols., Glasgow, 1755), with a biography by Dr. William Leechman. Truth he divides into logical, moral, and metaphysical. Logical truth is the agreement of a proposition with the object it relates to; moral truth is the harmony of the outward act with the inward sentiment; and metaphysical truth is that nature of a thing wherein it is known to God as that which actually it is, or in other words it is its absolute reality. He maintained that besides the five external senses we possess also internal senses, one of which occasions the emotions of beauty and sublimity, and another gives rise to the moral feelings. He introduced the term moral sense, and maintained the existence of certain universal propositions, derived not from experience, but from the connate power of the mind (*menti congenita intelligendi vis*).

HUTCHINSON, a S. E. county of Dakota, intersected by the James or Dakota river; area, 432 sq. m.; pop. in 1870, 37. The surface is diversified, the soil good. Capital, Maxwell.

HUTCHINSON, Anne, founder of a party of Antinomians in New England, born at Alford, Lincolnshire, England, in 1591, died near New Amsterdam (now New York) in August, 1643. She was the daughter of the Rev. Francis Marbury. Becoming interested in the preaching of John Cotton, and of her brother-in-law John Wheelwright, she followed the former to New England with her husband, arriving in Boston Sept. 18, 1634. She was admitted a member of the Boston church, and rapidly acquired influence. She instituted meetings of the women of the church to discuss sermons and doctrines, in which she gave prominence to peculiar speculations which even on her voyage had attracted the attention and caused the displeasure of her fellow passengers. Such were the tenets that the person of the Holy Spirit dwells in every believer, and that

the inward revelations of the Spirit, the conscious judgments of the mind, are of paramount authority. Two years after her arrival the strife between her supporters and her opponents broke out into public action. Among her partisans were Vane, Cotton, Wheelwright, and the whole Boston church with the exception of five members, while the country clergy and churches were generally united against her. "The dispute," says Bancroft, "infused its spirit into everything; it interfered with the levy of troops for the Pequot war; it influenced the respect shown to the magistrates, the distribution of town lots, the assessment of rates; and at last the continued existence of the two opposing parties was considered inconsistent with the public peace." The peculiar tenets of Mrs. Hutchinson were among the 82 opinions condemned as erroneous by the ecclesiastical synod at Newtown, Aug. 30, 1637; and in November she was summoned before the general court, and after a trial of two days was sentenced with some of her associates to banishment from the territory of Massachusetts, but was allowed to remain during the winter at a private house in Roxbury. It was her first intention to remove to the banks of the Piscataqua, but changing her plan she joined the larger number of her friends, who, led by John Clarke and William Coddington, had been welcomed by Roger Williams to his vicinity, and had purchased by his recommendation from the chief of the Narragansetts the island of Aquidneck, subsequently called Rhode island. There a body politic was formed on democratic principles, in which no one was to be "accounted a delinquent for doctrine." The church in Boston, from which she had been excommunicated, vainly sent a deputation to the island with the hope of reclaiming her. After the death of her husband in 1642, she removed with her surviving family into the territory of the Dutch. The Indians and the Dutch were then at war, and in an invasion of the settlement by the former her house was attacked and set on fire, and herself and all her family, excepting one child who was carried captive, perished either by the flames or by the weapons of the savages.

HUTCHINSON, John, an English Puritan revolutionist, born in Nottinghamshire about 1616, died in Sandown castle, Kent, Sept. 11, 1664. He was a man of family and of good education, and was married at Richmond, July 3, 1638, to Lucy, daughter of Sir Allen Apsley, governor of the tower of London, with whom he subsequently settled on his estate at Owthorpe. After the commencement of the civil war he declared for the parliament and was appointed governor of Nottingham castle, which he held until the close of the war. He afterward represented Nottingham in parliament, and, as a member of the high court of judiciary appointed for the trial of the king, concurred in the sentence pronounced on him. The subsequent course of Cromwell, however, met with

the disapproval of Hutchinson. At the restoration he was comprehended in the general act of amnesty, but was subsequently arrested on a suspicion of treasonable conspiracy, and after a detention of ten months in the tower was removed to Sandown castle, where he died of an aguish fever brought on by confinement in a damp cell. His wife survived him many years, and left a memoir of him, which is valuable as a record of events. It was first published from the original manuscript in 1806 (4to, London), and several other editions have since appeared.

HUTCHINSON, John, an English philosopher, born at Spennithorne, Yorkshire, in 1674, died Aug. 28, 1737. After receiving a careful private education, he served as steward in several noble families. As riding purveyor of the duke of Somerset, master of the horse, he made a large collection of fossils. In 1724 appeared the first part of his "Moses's Principia," in which he disputed the Newtonian theory of gravitation. In the second part (1727) he continued his criticisms of Newton, and maintained on Biblical authority the doctrine of a *plenum* in opposition to that of a *vacuum*. From this time one or more of his uncouthly written volumes, containing a sort of cabalistic interpretation of the Hebrew Scriptures, appeared annually. His leading idea is that the Scriptures contain the elements of all rational philosophy as well as of general religion. The Hebrew language has not only its literal but its typical sense, every root of it being significant. His philosophical and theological works were published in London in 13 vols. (1749-'65).

HUTCHINSON, Thomas, governor of the province of Massachusetts, born in Boston, Sept. 9, 1711, died at Brompton, near London, in June, 1780. He was the son of a merchant of Boston who was long a member of the council, and graduated at Harvard college in 1727. After engaging without success in commerce, he began the study of law. He represented Boston for ten years in the general court, of which he was for three years speaker. He became judge of probate in 1752, was a councillor from 1749 to 1766, lieutenant governor from 1758 to 1771, and was appointed chief justice in 1760, thus holding four high offices at one time. In the disputes which led to the revolution he sided with the British governor. The mansion of Hutchinson was twice attacked in consequence of a report that he had written letters in favor of the stamp act, and on the second occasion (Aug. 26, 1765) it was sacked, the furniture burned in bonfires in the street, and many manuscripts relating to the history of the province, which he had been 30 years in collecting and which could not be replaced, were lost. He received compensation for his losses, but none of the assailants were punished, although the proceedings were denounced by resolution in a public meeting. In 1767 he took a seat in the council, claiming

it *ex officio* as lieutenant governor; but both the house and council resisted his pretension, and he abandoned it. The legislature was inclined to restore him to the council in 1768, until it was announced by his opponent James Otis that he received an annual pension of £200 from the crown. When in 1769 Gov. Bernard was transferred to Virginia, the government of Massachusetts fell to Hutchinson. The popular excitement had already been increased by the arrival of British troops, and after the Boston massacre a committee of citizens, headed by Samuel Adams, forced him to consent to the removal of the regiments. He received his commission as governor in 1771, and his whole administration was characterized by duplicity and avarice. In 1772 Benjamin Franklin, then in London, procured some of the confidential letters of Hutchinson and his brother-in-law Andrew Oliver; these were forwarded to Massachusetts, and proved that he had been for years opposing every part of the colonial constitution, and urging measures to enforce the supremacy of parliament; and the result was a petition to the king from the assembly and the council praying for his removal from the government. The last of his public difficulties was when the people of Boston and the neighboring towns determined to resist the taxation on teas consigned by the East India company, two of the consignees being sons of Gov. Hutchinson. The popular committees were resolved that the tea should not be landed, but should be reshipped to London. A meeting of several thousand men, held in Boston Dec. 18, 1773, demanded the return of the ships, but the governor refused a pass. On that evening a number of men disguised as Indians repaired to the wharf, and emptied 342 chests of tea, the whole quantity that had been imported, into the bay. In the following February the governor sent a message to the legislature that he had obtained his majesty's leave to return to England, and he sailed on June 1. The privy council investigated his official acts, and decided in favor of "his honor, integrity, and conduct." He was rewarded with a pension. He published the following works: "The History of the Colony of Massachusetts Bay, from the First Settlement thereof in 1628 until the Year 1750" (2 vols., London, 1765-'7); "A Brief State of the Claim of the Colonies" (1764); and a "Collection of Original Papers relative to the History of the Colony of Massachusetts Bay" (1769). From his manuscripts a history of Massachusetts from 1749 to 1774 was prepared by his grandson, the Rev. John H. Hutchinson, of Trentham, England (1828).

HUTTEN, Ulrich von, a German scholar and reformer, born in the castle of Steckelberg, near Fulda, April 20 or 22, 1488, died in Switzerland, Aug. 29, 1523. When 11 years old he was placed in the monastery of Fulda, that he might there become a monk; but at 15 he ran away from the cloister to the university of

Erfurt, where he was supported by his friends and relatives. A disease then new to Europe raged in many places, and when it appeared in the summer of 1505 in Erfurt both students and teachers took to flight. Hutten went to Cologne, where he studied the writings of Thomas Aquinas and Duns Scotus. This city was the stronghold of the old system, led by Ortwein, Hoogstraten, Tungern, Pfefferkorn, and all who were then termed *Dunkelmänner* or "Obscurants." Here, in the headquarters of monkish peculiarities, Hutten collected materials for the sketches of the *Epistolæ Obscurorum Virorum*. Even in Cologne, however, the new spirit of classic study had found a home under the care of Johannes Rhagius, who endeavored to form a taste for the works of classical antiquity and what was then termed poetry, a word limited by the Obscurants to pure and ancient Greek and Latin metrical composition. Hutten became his friend and pupil, and, when he was driven away under the accusation of corrupting youth and theology, followed him to Frankfort-on-the-Oder, where a new university was opened in 1506. At the inauguration Hutten published his first poem, *Carmen in Laudem Marchie*, in praise of the mark of Brandenburg. Here he received the degree of M. A., and remained till 1508. The disease which had driven him from Erfurt again seized on him, and he sought health in travel. In northern Germany he was everywhere warmly received, but was wrecked on the Baltic and reduced to great poverty. In this condition he went to the university of Greifswald, and was kindly provided with clothing and hospitably entertained by the burgomaster Wedeg Lötze, and by his son, a professor in the university. An unexplained change in their treatment of him compelled him to leave the town; and on the way, late in December, he was set upon by their servants, lying in wait for him, beaten, stripped of the garments furnished him, and robbed of all his money and papers. In this condition, diseased and wounded, he came to Rostock, where he wrote a famous satire on Lötze (*Klagen gegen Lötze*), calling on all the scholars of the new school in Germany to avenge him. In Rostock he lectured on the classics, established intimate relations with the professors, and worked for the interests of the classic school. In 1511 he went to Wittenberg, where he published his *Ars Versificatoria*, regarded in its day as a masterpiece. Thence he wandered through Bohemia and Moravia to Vienna, where for a time he appears to have been prosperous and courted. Finally arriving at Pavia in April, 1512, Hutten resolved to study law. But three months later the city was besieged by the emperor Maximilian, and Hutten, who had taken part in the contest, believed himself in danger of death, and wrote his famous epitaph. Plundered of all he possessed, he fled to Bologna. Here his disease broke out again, and, repulsed by every one,

badly treated, and starving, he enlisted as a soldier in the emperor's army. The results of his Italian studies were embodied in the satire of *Ὀβρις* ("Nobody"). He returned to Germany, suffering from his old disease, in 1514. He thought he had succeeded in effecting a cure by the use of gum guaiacum, and wrote a treatise, *De Guaiaci Medicina et Morbo Gallico*. An accident now brought him into note. Duke Ulrich of Würtemberg had fallen in love with the wife of his cousin Johann von Hutten, and murdered the husband. When Hutten heard of this he wrote his "Deplorations," in which he cried for vengeance. He availed himself of this deed to call on German towns to free themselves from ducal tyranny. His denunciations made the tyrant a byword. But a short time elapsed before Hutten found himself in a new quarrel, ardently defending Reuchlin, who as a scholar was protesting against the wholesale destruction of all Hebrew books, for which the Cologne Obscurants were clamoring. With the aid of many friends he published the celebrated *Epistole Obscurorum Virorum*, a work which greatly aided the reformation, and previous to this his *Triumphus Captonis* ("The Triumph of Reuchlin"), the publication of which was long delayed by the scruples of Erasmus. In 1515 he again went to Rome, ostensibly to study law; but having become involved in a quarrel, he fled to Bologna, which he was obliged to quit for a like reason. After visiting Ferrara and Venice, he found it necessary to return to Germany. At Augsburg he was presented to the emperor, who gave him in public the spurs of knighthood. He was then sent by the elector of Mentz on a mission to Paris, where he established intimate relations with the learned. Retiring to his family castle of Steckelberg, Hutten, having written by way of introduction several epigrams on Pope Julius II., edited the work of Laurentius Valla entitled *De Falso Credita et Ementita Donatione Constantini Magni* (1517). In 1518 he found a protector in Albert, margrave of Brandenburg, whom he invited in a glowing panegyric to place himself at the head of united Germany. In the same year he accompanied the margrave to the diet of Augsburg, where Luther was to reply to Cajetan. But "Hutten, now the brilliant knight, troubled himself but little as to the poor Augustinian monk;" he was full of a project for uniting the princes of Europe against the Turks, and was fascinated with the idea of becoming an influential statesman. The work in which he preached this crusade he printed himself at Steckelberg in 1519, intitling it *Ad Principes Germaniæ, ut Bellum Turcis inchoant Exhortatoria*. In it he upbraids the court of Rome and the German nobility. These latter had been previously more fiercely attacked in his "Dialogue of the Court Enemy," in which Hutten boldly assumes a tone like that of modern republicanism. In 1519 he left the margrave to join

Franz von Sickingen in the Swabian league against his old enemy Ulrich of Würtemberg. Yet during this war he wrote the "Triad," a most vehement diatribe against Rome, and edited two books of Livy hitherto unpublished. The war over, he retired to the castle of Sickingen, whence he sent forth the bitterest attacks on Rome. He discovered in the library of Fulda a manifesto of Henry IV. against Gregory VII., and turned its German sentiment to such account that Leo X. demanded him as a prisoner. Driven from his castle, he took refuge in Ebernburg, and now began to write in German prose and verse; and these tracts are among his most daring productions. For a short time he fought in the army of Charles V. at the siege of Metz; and at this time Francis I. offered him the place of councillor at his court. Hutten next wandered to Switzerland, and Ecolampadius led him to Basel, where he hoped for support from Erasmus, who however turned against him, and even took pains to set the council of Zürich against him. Finally Zwingli obtained for him an asylum on the island of Ufnau in the lake of Zürich, where, worn out by war and suffering, he ended his short and tumultuous life. Among his works not mentioned above are *Dialogi*, *Fortuna*, *Febris* (including the *Trias*, Mentz, 1520), and his poems (Frankfort, 1538). His collected works were published by Münch (6 vols., Berlin, 1821-'7). An *Index Bibliographicus Huttenianus* was published by Böcking at Leipsic in 1858, and a new edition of his works in 7 vols. in 1859. Many biographies of Hutten have been written; one of the best and most recent is that by Strauss (2 vols., Leipsic, 1857; 2d ed., 1871).

HUTTON, Charles, an English mathematician, born in Newcastle-on-Tyne, Aug. 14, 1737, died Jan. 27, 1823. At the age of 18 he became an usher in the village of Jesmond, and some years later the master of the school. In 1760 he removed to Newcastle, where he wrote his "Practical Treatise on Arithmetic and Book-Keeping" (1764). His "Treatise on Mensuration" (1771), and "Principles of Bridges, and the Mathematical Demonstration of the Laws of Arches" (1772), led to his being chosen in 1773 professor of mathematics in the military academy of Woolwich. He was elected fellow of the royal society in 1774, and was foreign secretary of that body from 1779 to 1783, when he resigned. He published a large number of papers in its "Transactions," and made all the mathematical calculations for Maskelyne's experiments for determining the mean density of the earth. About 1795 he undertook, aided by Drs. Pearson and Shaw, the labor of abridging the "Philosophical Transactions." The work was completed in 1809, Hutton receiving £6,000 for his share in it. Being compelled by bad health to resign his professorship at Woolwich, he received a retiring pension of £500. His principal works, in addition to those above mentioned, are: "Tables

of the Product and Powers of Numbers" (London, 1781); "Mathematical Tables" (1785); "Course of Mathematics" (3 vols., 1793); and "Mathematical and Philosophical Dictionary" (2 vols. 4to, 1795). He was also for many years editor of the "Ladies' Diary."

HUTTON, James, a British natural philosopher, born in Edinburgh, June 3, 1726, died March 26, 1797. He entered the university of Edinburgh in 1740, and began the study of law, which he subsequently abandoned for medicine, taking the degree of M. D. at Leyden in 1749. He engaged in the manufacture of sal ammoniac from coal soot, inherited from his father a small estate in Berwickshire, betook himself to agriculture, finally removed to his native city in 1768, devoting himself especially to the study of geology, and made several important discoveries. In 1795 he published the results of 30 years' study in his "Theory of the Earth," assuming that heat is the principal agent of nature.

HUXLEY, Thomas Henry, an English naturalist, born in Ealing, Middlesex, May 4, 1825. He spent two and a half years at Ealing school, in which his father was one of the masters, but with this exception his education was carried on chiefly at home. In 1842 he entered the medical school of Charing Cross hospital, and in 1845 received the degree of M. B. from the university of London, being placed second in the list of honors for anatomy and physiology. He began his literary career while yet a student by contributing to the "Medical Times and Gazette" a paper on that layer in the root sheath of hair which has since borne his name. In 1846 he joined the medical service of the royal navy, and was stationed at Haslar hospital, whence he was selected the same year to accompany Capt. Stanley, as assistant surgeon of the Rattlesnake, in his expedition to the South Pacific. After a four years' voyage of circumnavigation, during which surveys of the east coasts of Australia and Papua were made, the ship returned to England in November, 1850. While absent Mr. Huxley, who made extensive observations on the natural history of the seas traversed, sent home a number of communications, the first of which, read before the royal society in 1849, is "On the Anatomy and Affinities of the Family of the Medusæ." On his return some of these papers were elaborated by him and published in the "Philosophical Transactions" of the royal society, of which, in June, 1851, he was elected a fellow. In 1853 he resigned his position in the navy, and in the following year he succeeded Prof. Edward Forbes as professor of natural history in the royal school of mines, an office which he still holds (1874). He has since resided in London, where he has devoted himself to constant scientific labor and research. In addition to his annual course of lectures on general natural history, he has delivered many lectures on kindred subjects to mixed audiences, and has done much to popularize sci-

ence. He was Hunterian professor in the royal college of surgeons from 1863 to 1869, and was twice chosen Fullerian professor of physiology in the royal institution. In 1869 and 1870 he was president both of the geological and the ethnological society; in 1870 he was president of the British association for the advancement of science; and in 1872 he became secretary of the royal society. Since 1870 he has been a member of the royal commission on scientific instruction and the advancement of science. From 1870 to 1872 he served on the London school board, where he was chairman of the committee which drew up the scheme of education adopted in the board schools. During this time he took an active part in its deliberations, and became conspicuous by his opposition to denominational teaching, and particularly by his denunciation of the doctrines of the Roman Catholic church. In 1872 he was elected lord rector of the university of Aberdeen.—Prof. Huxley has done as much probably as any living investigator to advance the science of zoölogy, and the world is indebted to him for many important discoveries in each of the larger divisions of the animal kingdom. His earlier labors were devoted chiefly to the lower marine animals, with which he formed a most thorough empirical acquaintance during his Pacific voyage, and he has described many which previously had been either unknown or very imperfectly studied. During the past ten years he has devoted himself assiduously to the comparative anatomy and the classification of the vertebrata, and has embodied the results of his more important researches in numerous monographs. In his first published work, on the medusæ, he called attention to the fact that the body of these animals is formed of two cell layers, which may be compared to the two germinal layers of the higher animals; an idea which has since found its complete expression in the gastræa theory of Haeckel. To him also is due the vertebral theory of the skull, which has since been demonstrated so clearly by Gegenbaur; and he was the first to extend to man Darwin's theory of natural selection. In his three lectures on "Man's Place in Nature," delivered in 1863, he made an elaborate exposition of the doctrine of evolution as applied to man, asserting that the anatomical differences between man and the highest apes are of less value than those between the highest and the lowest apes. Among his many popular lectures, that "On the Physical Basis of Life," delivered in 1868, has attracted much attention. In it he advances the idea that there is some one kind of matter common to all living beings; that this matter, which he designates as protoplasm, depends on the preëxistence of certain compounds, carbonic acid, water, and ammonia, which when brought together under certain conditions give rise to it; that this protoplasm is the formal basis of all life, and therefore all living powers are cognate, and all living forms,

from the lowest plant or animalcule to the highest being, are fundamentally of one character. Prof. Huxley is a corresponding member of the principal foreign scientific societies, and has received honorary degrees from the universities of Breslau and Edinburgh. His works are as follows: "The Oceanic Hydrozoa" (1857); "Evidence as to Man's Place in Nature" (1863); "Lectures on the Elements of Comparative Anatomy" (1864); "Lessons in Elementary Physiology" (1866); "An Introduction to the Classification of Animals" (1869); "Lay Sermons, Addresses, and Reviews" (1870); and "Critiques and Addresses" (1873). He is the author also of a large number of papers published in the journals of the royal, the Linnæan, the geological, and the zoological societies, and in the memoirs of the geological survey of Great Britain.

HUY, a town of Belgium, in the province and 16 m. S. W. of the city of Liège, at the entrance of the Hoyoux into the Meuse; pop. in 1866, 11,055. It has a handsome Gothic church, a college, manufactories of paper, leather, and faience, distilleries, and an active trade. The former abbey of Neufmoutier contained the tomb of Peter the Hermit, by whom it had been founded; in 1858 a statue was erected in his honor in the garden of the abbey. In the neighborhood there are mines of iron, zinc, and coal, and several mineral springs.

HUYGENS (incorrectly HUYGHENS), **Christian**, a Dutch natural philosopher, born at the Hague, April 14, 1629, died there, July 8, 1695. He was the second son of Constantine Huygens, secretary and counsellor of the stadtholders Frederick Henry, William II., and William III. His father taught him the rudiments of education and the elements of mechanics. At the age of 15 he became the pupil of Stampion, and at 16 he was sent to Leyden to study law with Vinnius, who dedicated to him his first commentary on the Institutes of Justinian. He there also pursued mathematical studies, and afterward at Breda in the university, which was under the direction of his father. In 1650, after a journey to Denmark with Henry, count of Nassau, he began those mathematical and physical researches which afterward made him famous. In 1651 he published at Leyden his first work, on the quadrature of the hyperbola, the ellipse, and the circle, and in 1654 a paper entitled *De Circuli Magnitudine inventa nova*. In 1655 Huygens went for the first time to France, and received the degree of doctor of laws from the faculty of the academy of Angers. On his return to Holland he turned his attention to the construction of telescopes, in connection with his elder brother Constantine. With one of these instruments, having a focal length of 10 ft., and more powerful than any ever before made, he discovered the first (now called the fourth) satellite of Saturn, and published the discovery at the Hague in 1656. During the next year he wrote a paper on the calculus of probabilities. Pascal and Fermat

had already written upon the subject, but the treatise of Huygens was more profound, and 50 years afterward James Bernoulli employed it as an introduction to his *Ars Conjectandi*. It was also translated into Latin by his former tutor Schooten under the title *De Ratiociniis in Ludo Aleæ*, by which it is also known in 's Gravesande's edition of Huygens's works. Schooten published it in his *Exercitationes Mathematicæ*, to demonstrate, as he says, the utility of algebra. About this time Huygens sent a paper to Wallis on the area of the cissoid, and to Pascal a calculation for hyperbolic conoids, and spheroids in general, and on the quadrature of a portion of a cycloid, in which papers he employed methods having the highest characteristics of original thought. But his attention was not wholly devoted to merely theoretical mathematics, for about this time he introduced one of the most practical and important of all inventions. Galileo had observed the isochronism of small vibrations of the pendulum, and had employed it as a measurer of time, but his method required an assistant to count the oscillations, and was of course far from being exact. To keep the pendulum in motion and cause it to register its successive vibrations was one of the problems which Huygens attempted, and which he succeeded in solving by the invention of the pendulum clock, a description of which, under the title of *Horologium*, he dedicated to the states general of Holland in 1658. (See CLOCKS AND WATCHES.) In 1659 he constructed a telescope of 22 ft. focal length, in which he used a combination of two eye pieces, and again examined Saturn, making the discovery of the ring of the planet. The singular appearance which it sometimes presents of being accompanied by two luminous bodies, one on either side, had been observed by Galileo, but his telescope had not sufficient power to permit him to discover its cause. Huygens's instrument enabled him to make out that the phenomenon in question, which at regular times appeared and disappeared, was produced by the oblique position of the ring with regard to the earth and to the sun. From an analysis of the phenomenon he predicted the disappearance of the ring in 1671, and the prediction was verified. He published an account of these observations at the Hague in 1659, in a volume also containing an account of several other discoveries, such as that of the great nebula in the sword of Orion, the bands upon the disks of Jupiter and Mars, and the fact that the fixed stars have no sensible magnitude. It was also accompanied by a description of a method for measuring the diameter of the planets. The micrometer used by him has been superseded by others, but it served the purpose of making correct measurements. In 1660 he visited France and England, and soon after published his celebrated theorems on the laws of the impact of bodies, in which most of the principles of the laws of motion are es-

tablished. In 1665, at the invitation of Colbert, he went to France and became a member of the academy of sciences, then recently formed. Apartments were assigned to him in the royal library, and he resided in Paris for the greater part of the next 15 years, during which time he presented many papers to the academy, some of which still remain unpublished in its archives. In 1670 he visited Holland to restore his health, which had become impaired by his great labors; and on his return to Paris in the following year he completed his great work *Horologium Oscillatorium* (fol., Paris, 1673). To this book are appended 13 theorems on centrifugal force, which will be noted further on. About this time he invented the spiral spring which is applied to the balance wheel of watches, a description of which was published in the journal of the academy of sciences in 1675. The invention was claimed by Hooke of England and Hautefeuille of France, but the evidence that it is the invention of Huygens is too strong to be any longer questioned. It is said that the first watch provided with a hair spring was made by Thuret under Huygens's direction, and was sent to England. In 1675 he again went to Holland for the benefit of his health, and in 1676 he read before the academy of sciences his famous treatise on light, and also a treatise on the cause of gravity, in which he attempts to account for the force by supposing that ethereal matter revolves about the earth with a velocity greater than that of the planet, and compares it to the force which causes bodies a little heavier than water, and lying lightly upon the smooth bottom of a cylindrical vessel containing water, to move toward the centre when the circular motion of the vessel by which its fluid contents have been caused to revolve is arrested. In 1681 he returned to his native country, and immediately began the construction of an automatic planetarium to represent the true motion of the bodies of the solar system. This invention led to the important discovery of continued fractions, which he found it necessary to employ in order to establish the relation between the number of teeth contained in two wheels which play into one another. After this he resumed for several years, in conjunction with his brother Constantine, the construction of telescopes. He made two objectives, one of 170 and another of 210 ft. focal length, which he presented to the royal society of London. As a telescope of such dimensions would be difficult to manage, Huygens proposed to dispense with the tube and place the object glass in an elevated position so that it could be adjusted to any angle, and then to place the eye piece at the focus. This arrangement continued to be used until the introduction of reflecting telescopes. While Huygens was absorbed in these occupations a great revolution was going on in the mathematical world. Leibnitz had invented the differential calculus, which he published in 1684, and

had proposed as a test to the followers of the old methods the problem of finding the curve of equable approach, or that which a suspended body must follow in order to approach or recede from equal heights in equal times. Huygens accomplished the solution by the old methods, but he was the only one who succeeded. Soon after this Newton published his *Principia*, and Huygens, with a desire of becoming acquainted with the author, visited England for the third time, and on his return published his treatise on light under the title *Traité de la lumière, où sont expliquées les causes de ce qui lui arrive dans la réflexion, dans la réfraction et particulièrement dans l'étrange réfraction du cristal d'Islande* (Leyden, 1690). Soon after this he investigated the properties of the catenary curve, a problem which had just been proposed by James Bernoulli, who had become proficient in the methods of the differential calculus; but Huygens solved the question by the old methods, which was considered a wonderful achievement. He nevertheless found the task so difficult that his opposition to the differential calculus was shaken, and he entered at once into correspondence with Leibnitz. He had previously, whenever meeting with difficulties, attributed them to himself and not to defects in the methods. After examining the differential calculus he admitted its superiority, immediately commenced its use, and soon gave a wider development to the invention than it had yet attained. At his death he left his manuscripts to the library of Leyden, intrusting their publication to two of his pupils, Volder and Fullen.—Huygens was never married, and aside from his scientific pursuits his life was not eventful. He had a fine personal appearance, and his character was eminently noble. Newton spoke of him as the *summus Hugenius*, and considered his style as an author more classic than that of any other mathematician of that time. He was affable and kind, and was easily accessible to young students, whom he was always delighted to assist in their investigations. His labors were immense, and the practical value of their results is inestimable. His discovery of the laws of the double refraction of light in Iceland spar, and of polarization, perhaps as much as any other cause, led to the reëxamination of the undulatory theory, and, with the necessary adaptations, to its employment to account for all the phenomena of radiation of both heat and light. In accordance with this theory the most important researches in modern physics have been made, as those upon the diathermanous properties of bodies, and upon the absorption of radiant heat by gases and vapors, by which great light has been thrown on the science of meteorology. Besides his invention of the pendulum clock and of the balance wheel to the watch, the first chronometers taken aboard ships were made under his direction, and he was far in advance of all others

of his day in astronomical observations. His discovery of the isochronism of the cycloid was one of the most important in mathematics; and not inferior to it is the invention of the involu- tion and evolution of curves, and the es- tablishment of the proposition that the cycloid is its own evolute. He also, in his *Horologium Oscillatorium*, gives a method for finding the centre of oscillation, which was the first suc- cessful solution of a dynamical problem in which connected material points are supposed to act on one another. The difficulty of this subject is shown by the fact that Newton fell into an error in regard to it in attempting to solve the problem of the precession of the equinoxes. The question of the centre of os- cillation had been proposed by Mersenne in 1646, and although some cases had been solved on the principle of the centre of percussion, it was beyond the reach of any methods then known. Huygens was only a boy of 17 when the question was proposed, and could then see no principle by which it could be solved; but when he published his *Horologium Oscillato- rium* in 1673, the principles which he assumed led to correct results in all cases. The two first theorems appended to that work state: 1, that if two equal bodies move in unequal circles in equal times, the centrifugal forces will be proportional to the diameters of the circles; and 2, that if the velocities are equal, the cen- trifugal forces will be in the inverse ratio of the diameters. To arrive at these conclusions required the application of the second law of motion (*i. e.*, that the motion which a force gives to a body is compounded with the motion which it previously had) to the limiting ele- ments of the curve, in the manner in which Newton afterward demonstrated the theorems of Huygens in his *Principia*. Huygens's own demonstrations of these theorems were found after his death among his papers. In his treatise on the impact of bodies (*De Motu Corporum ex Percussione*), Huygens must have assumed the third law of motion, which New- ton afterward expressed by saying that "action and reaction are equal and opposite," by which we understand that the quantity of motion in the impact of bodies remains unchanged, one of the first grand principles in the doctrine of the conservation of force. His works were edited by 's Gravesande under the titles of *Opera varia* (2 vols. 4to in 1, Leyden, 1724) and *Opera Reliqua* (2 vols. 4to, Amsterdam, 1728).

HYACINTH, a genus of *liliaceæ*, containing several species, the most important of which is *hyacinthus orientalis*, a native of the Levant. This has an onion-like bulb, which throws up long, narrow-channelled leaves, from among which arises a scape bearing a raceme of bell-shaped drooping flowers; the parts of the perianth are united to about the middle, and the free portions reflexed; flowers often very fragrant, appearing in early spring. This being one of the florists' flowers, great changes have been produced in it by cultivation; the size of

the flower cluster has been greatly increased, the flowers are semi-double and double, and there is a great variety of colors and tints, from pure white, through various shades of red and blue, to nearly black. The number of named varieties is very large, and includes not only self-colored ones, but double and single kinds, with flowers variously striped and shaded. The bulb growers near Haarlem in Hol- land supply the world with hyacinths, which form a large share of what are imported under the name of "Dutch bulbs." The eminence of the Dutch florists in the culture of this and other bulbs is in part due to a favorable soil and climate, and in part to the patient care given to their cultivation; these, with the low price of labor, have enabled them to hold a monopoly of bulb growing. Near Haarlem over 100 acres of land are annually devoted to hyacinths; the soil is a mixture of sand and alluvium, and permanently supplied with the requisite moisture. New varieties are obtained by sowing seed, and it is necessary to cultivate the seedlings for six years before their real

Hyacinth Bulb and Section.

merit can be decided upon. Established var- ieties are multiplied from the small bulbs which form at the base of the larger ones; a bulb will naturally produce several of these, and the cultivators increase the number by wounding and cutting the bulb in various ways. The small bulbs are carefully cultiva- ted until of a proper size for market; in or- der to increase its size as rapidly as possible, the bulb is not allowed to exhaust its strength in producing flowers, but the flower stem is cut away as soon as it appears. Millions of bulbs are annually imported into this country and England, and large quantities go to other countries. The best are imported by the deal- ers direct from the growers; it is only the poorer bulbs, from which the finer ones have been selected, that are usually offered at auc- tion. The different varieties are put up in bags of heavy paper, with an abundance of the hulls of buckwheat, and the bags are packed in cases. The heaviest bulbs, which show no signs of decay by being soft at the top, are

to be preferred. Named sorts cost much more than assorted kinds, which for the general cultivator may be quite as satisfactory as those

Hyacinth (*H. orientalis*).

with names. The bulbs for outdoor culture are usually planted in October. A rich light soil is best, and well decomposed cow manure is the best fertilizer; the bulbs should be set 8 in. apart and covered to the depth of 4 in.; when cold weather comes on, the bed is to be covered with litter, which is to be left on until spring; when the plants come into flower each spike will need the support of a small stick or wire, which may be so placed as not to be noticed; when the flowers decay their stalks are cut away, and the bulbs allowed to remain until the fading of the leaves shows that they have finished their growth; they are then taken up, dried in the sun, each wrapped in a paper with its label, and kept in a cool dry place until time to plant in autumn. They do not bloom in subsequent years so well as the first. In some gardens the bulbs are left

English Bluebell.

from year to year; they increase and form large clumps, which produce small spikes of flowers. The hyacinth is an easy plant to force

in the greenhouse or in an ordinary room; the bulbs should be potted in October, and the pots placed in a cool dark cellar, or in a shady corner, and covered with coal ashes; when an inspection of the pots shows that the ball of earth is well filled with roots, they may be brought to a warm and light place, when growth of leaves and flowers will soon commence; frequent failure is due to not first securing a good growth of roots by keeping the bulb cool and from the light. The bulbs are often forced in glasses made for the purpose, filled with water; the base of the bulb should just touch the surface of the water, and the glass should be kept in the dark until the roots are well developed. Bulbs that have been forced are of little value; single varieties are preferred for forcing.—The wild hyacinth, the bluebell of England, *H. nonscriptus* of the older botanists, has been successively placed in several different genera, and is probably nearer a squill (*scilla*) than a hyacinth.

HYACINTHE, Père. See LOYSON, CHARLES.

HYACINTHUS, in Greek mythology, son of the Spartan king Amyclas and Diomedé, or of Pierus and Clio, or of Cebalus and Eurotas. He was a boy of great beauty and the favorite of Apollo, but was also beloved by Zephyrus, who from jealousy caused his death as he was playing with Apollo, by blowing the quoit of the god against his head. From his blood sprang the flower hyacinth, upon whose leaves appears the Greek exclamation of woe ΑΙ, ΑΙ, or the letter Υ beginning his name (Υάκινθος).

HYADES, in Greek mythology, nymphs variously described as being from two to seven in number, and bearing 18 names. According to some authorities, Jupiter placed them among the stars in honor of their care of the infant Bacchus; while others say it was to reward them for their long mourning for their brother Hyas, who had been killed by a wild boar.

HYÆNA, a digitigrade carnivorous mammal, most numerous in Africa, but found also in southern and middle Asia, where the genus has probably spread while following the track of armies and caravans. Zoölogists are not agreed as to the position of this animal; the older authors place it in the feline family, with which it agrees in the single true molar on each side of both jaws, and in the single tuberculate tooth on each side of the upper jaw only; Waterhouse regarded it as a small divergent group of *viverrina* or civet cats; Linnæus ranked it in his genus *canis*; and Hamilton Smith puts it in juxtaposition to the dogs. It seems to be an osculant type, united on the one hand to the dogs by the genus *lycaon*, and on the other to the civets by the genus *proteles* (aard-wolf); its general aspect is decidedly canine, as also are most of its habits. The dental formula, according to Owen, is: incisors $\frac{6}{6}$, canines $\frac{2}{2}$, premolars $\frac{4-4}{3-3}$, and molars $\frac{1-1}{1-1}$ —34 in all. The disposition of the hyæna is fierce and cowardly, and its habits are revolting; it is able to withstand any temperatures and priva-

tions, revels in the foulest air, and gorges on the filthiest substances when living prey fails; of powerful form, thick skin, and strong jaws and teeth, the bands of hyænas fear not the lion and tiger, and will attack even man in the night time. Its appearance is very repulsive; the head is large and truncated, the neck short and stout, the body thick and short, high at the shoulders and declining rapidly toward the tail, a long stiff mane from the nape to the rump, and a short tail; the gait is clumsy, the voice harsh and frightful, the expression of the face malignant, and its body offensive from its carrion food and the strong odor of its anal pouch. The feet are all four-toed, with strong non-retractile claws fitted for digging, the dorsals and the pairs of ribs 15 or 16, and the lumbar vertebræ 4 or 5; the tibia and fibula are much shorter than the radius and ulna; the tongue is covered with horny papillæ, the irides elliptical above and circular below, the erect ears long and pointed, and mammae four. The prevailing color is an ochrey gray, with dark stripes or spots. The hyæna is among mammals what the vulture is among birds, the scavenger of the wilderness, the woods, and the shore, and useful in this way in disposing of carcasses which otherwise would pollute the air; often it attacks cattle and disabled animals, prowls in the rear of the larger carnivora, whose leavings it devours, and digs up when possible the dead bodies of man and beast; from this last undisputed habit, the hyæna has been regarded as a horrible and mysterious creature, and is the subject of many superstitious fears and beliefs among the Semitic races. Its teeth are so powerful that they can crack the bones of an ox with ease, and their grip is tenacious to the last degree; were its speed great and its courage equal to its strength, it would be among the most dangerous of the carnivora; it sometimes burrows in the earth or hides in caverns, but generally

Spotted Hyæna (*Hyæna crocuta*).

passes the day in the desert, insensible to the scorching sun. The spotted hyæna (*H. crocuta*, Erxl.) is the most dog-like of the genus; it is about 4½ ft. long from nose to base of tail, the latter measuring about 13 in. and the head about 12; the height at the shoulders is 2½

ft.; the general color is a dingy whitish gray, with small round brown spots, the muzzle as far as the eyes and lower limbs sooty, and the tail dark; the mane is rather short. It is found in South Africa, and on the coasts of Senegal and Guinea, and with the next spe-

Striped Hyæna (*Hyæna striata*).

cies is generally called wolf by the Dutch colonists. It is fierce but cowardly, and will sometimes approach camps and make severe gashes on the limbs and faces of persons asleep; it is said sometimes to drag off children, which from its strength it could easily do; from the resemblance of its voice to a human laugh, it has received the name of the laughing hyæna; it rarely burrows, but occupies the retreats of other animals, prowling about at night. The striped hyæna (*H. vulgaris*, Desm., or *H. striata*, Zimm.), a rather larger animal, is found in Africa, Asia Minor, Arabia, and Persia; the head is wider, the muzzle fuller, and the eyes further from the nose, than in the preceding species; the hair is coarse and thick, of a dirty gray color, with transverse dark stripes on the sides and limbs; there is a stiff mane along the back; the habits are the same as those of the spotted hyæna. There are some varieties of smaller size, and one with a skin almost naked, in the Nubian deserts. The brown hyæna, or strand wolf of the Dutch colonists (*H. brunnea*, Thunb.), is only 4 ft. long to the end of the tail, and a little over 2 ft. high at the shoulders; the hair is long and shaggy, of a dirty yellow color, with tawny tints on the back and irregular stripes on the sides; it is less in size than the other species, and less destructive to cattle. The hyænas act very much the part of the wolf of northern climates, being equally fierce, cowardly except at night and when in packs, and annoying to the herdsman by their destruction of sheep and oxen.— There are in Africa certain dog-like animals, the *wilde honden* of the Dutch, constituting the genus *lycaon* (Brooks), which seem to connect the dogs with the hyænas, and which are believed by Hamilton Smith to be partly the pro-

genitors of the mastiff races. The head is short and truncated, the mouth broad, the teeth strong and dog-like; the ears erect and large; neck long, body short, the limbs slender and highest before; tail short, hanging down, and inflexible; four toes on all the feet; pupils round; mammae eight or ten. They hunt in packs, being swift, active, hardy, with excellent scent and acute sight; they do not burrow. They are found in Africa south of the great desert, and in Arabia, and as far as the Indus in Asia. The hunting hyæna (*Lycaon venaticus*, Burch.) of the Cape is about as tall as a large greyhound, with long legs; the color is ochrey, white on the breast, with spots of the same edged with black on the neck, shoulders, loins, and croup, with wavy black streaks on the sides; the muzzle and cheeks black, the color passing up on the nape and down on the throat. It hunts in packs both by day and night, frequently destroying sheep, and sometimes surprising cattle, biting off their tails; it

Hunting Hyæna (*Lycaon venaticus*).

is considered untamable. The painted hyæna (*L. pictus*, Temm.) is by many thought to be a mere variety of the last; it is about 3 ft. long, the tail 1 ft. more, and 1½ ft. high at the shoulders; the colors are much the same as in the preceding animal; it hunts also in packs, surprising antelopes, and attacking when hard pressed for food cattle and even man; Rüppell says it looks much less like a hyæna and more like a dog than the *L. venaticus*.—In anterior geological epochs the hyænas were not confined to tropical Africa and Asia, nor to the old world. They appeared in Europe toward the end of the tertiary age, but were most numerous during the diluvial period, and were found in England, Belgium, and Germany; there were about half a dozen species, numerous in individuals, and of a size sometimes superior to the living animal. In the Kirkdale and other caverns of Europe three species are found, of which the best known is the *H. spelæa* (Goldf.). In Asia they were numerous in the Himalaya

region, of which the most remarkable is the *H. Sivalensis* (Cautl. and Falc.). In the caverns of Brazil Lund has found abundant remains of a hyæna which he calls *H. neogæa*, mixed with the bones of rodents, peccaries, megalonyx, and other American types, seeming to show that the geographical distribution of animals in the modern faunæ is in no way connected with their ancient distribution. The bones of the caverns bear unmistakable marks of the teeth of hyænas, even if the remains of the latter did not prove their existence; and this animal seems to have been the principal consumer of the great proboscidiæ and ruminants of the diluvial age.

HYBLA, the name of several cities of ancient Sicily, the most considerable of which were the following. **I. Hybla Major**, or **Magna**, situated on the southern declivity of Mt. Etna, near the river Symæthus. It was founded by the Siculi, and was one of those which Ducætiæ, a chief of that people, sought to unite into a confederacy against the Greeks and Carthaginians. In the time of Cicero Hybla Major was an opulent *municipium*, but in that of Pausanias it was a poor decayed place. Its site was probably at Paterno, where an altar has been discovered dedicated to *Venus Væctria Hyblensis*. **II. Hybla Minor**, which stood so near Megara on the E. coast, N. of Syracuse, that the two cities were often confounded, was likewise of Siculic origin. It was chiefly celebrated for the honey produced in its vicinity.

HYBRID (Gr. *ἕβρις*), an animal or plant produced by the sexual union of individuals belonging to two different species. As a rule, in nature sexual union takes place only between individuals of the same species, and the offspring accordingly presents the specific characters common to both its parents. It is in this way that the species is indefinitely maintained, with its distinctive characters, by the constant production of new individuals similar in appearance to the old and endowed with similar powers of reproduction. But union between a male and a female of different species, when fertile, produces an offspring which does not precisely resemble either of its parents, but presents a mixture in nearly equal proportions of their separate characters. Thus a mule, which is the most commonly known example of a hybrid, is neither a horse nor an ass, but something intermediate between the two, and is without the complete distinctive marks of any recognized animal species. One of the most important questions relating to hybridity is that of the possible fertility of sexual union between different species, and that of hybrids of the same or different kinds between themselves. In nature, the occurrence of hybridity is extremely rare. This may be due to the more or less complete inaptitude of the male and female generative products to unite with each other in such a way as to produce a fertile result. Thus the germ and pollen of different flowers, or the

ovum and spermatic fluid of different animals, may be incapable of fertilization, owing to peculiarities of their own internal constitution; and consequently their physical contact would produce no result. But there are other reasons upon which the non-occurrence of hybrids in nature may partly depend. Among animals there is an instinctive preference for sexual union with their own species rather than with others, and a similarity of habits, of locality, and general disposition, corroborates this preference, and alone makes it much more likely that sexual union, as a matter of fact, will take place between animals of the same species. A certain degree of similarity in the physical structure of the parents is essential to the fertility of their sexual union. Thus all the most frequent and most useful forms of hybridity occur between different species belonging to the same genus. The horse, for example, will breed with the ass, the zebra, and the quagga; the dog has been certainly known to breed with the wolf, and probably with the fox; the goat with the sheep, the ram with the roe; and it has been comparatively easy to obtain hybrids from the union of the rabbit and the hare. But a cross union is not necessarily fertile, even between species of the same genus; between those of different genera it is still more exceptional; and it is doubtful whether hybridity, either natural or artificial, has ever occurred beyond these limits. The second question of interest relating to hybridity is that of the fertility of hybrids among themselves. As a rule it may be said that hybrids are not fertile. Thus the mule does not reproduce itself, but is only obtained by a repetition of the union of the ass and the mare. The female mule will sometimes reproduce by union with either the horse or the ass; but in this case the offspring is no longer a mule, but reverts to the type of the original stock in precise proportion to the admixture of blood resulting from the union. Notwithstanding, therefore, that the mule and its mode of production have been known from time immemorial, and notwithstanding the recognized usefulness of its qualities in some respects, we have never been able to obtain an independent and self-reproductive breed of mules; that is, the hybrid has never acquired the physiological characters of a natural species. —The terms hybrid and hybridization are often vaguely used as applied to plants, and many are called hybrids which are only crosses between varieties. The name hybrid should be restricted to plants resulting from the seeds of one species fertilized by the pollen of another species; those forms produced by cross breeding between varieties of the same species should never be called hybrids, but crosses. It is to be regretted that horticulturists generally ignore this distinction and use the terms hybrid and cross as synonymous. Hybrid plants sometimes occur in nature, and are frequently produced artificially. In hybridizing, it is neces-

sary to prevent the flower used as the mother, or seed-bearer, from being fertilized by its own pollen both before and after the artificial application of the strange pollen; the operator is favored by the fact that pollen retains its vitality for some time after it is removed from the flower which produced it. It is probable that with this, as with seeds, the duration of vitality varies in different species; at all events, it is known that some pollen will keep for weeks and even months. The flower selected as the seed-bearer is taken just as it is about to open and before any insects can have visited it; the envelopes are carefully opened or removed, and if a perfect flower its still unopened stamens are cut away with a delicate pair of scissors, the foreign pollen applied to the stigma with a small brush, and the flower or flowers enclosed in a bag of gauze to prevent the access of insects, which would probably bring pollen of the same kind to interfere with the action of the strange pollen. This is a brief outline of the process; there are details which can be learned by practice. It is not possible to know beforehand whether two species will hybridize; two species of a genus that seem to be the most nearly related will sometimes refuse to be hybridized, while other two that seem most unlike will readily form a union. It makes a difference also which plant is chosen as the seed-bearer and which as the pollen-bearer; for instance, the pistil of A will refuse to be fertilized by the pollen of B, while the pistil of B will readily accept the pollen of A. Seeds from the flowers thus fertilized may produce plants quite intermediate between the two parents, or may more strongly resemble the one or the other. Sometimes a hybrid will have the leaves of one parent and the flowers and fruit of the other. By this means horticulturists have produced useful varieties of fruit, notably in grapes and strawberries, and some of the finest flowers are the result of hybridizing. Among hardy flowers, the rhododendrons and azaleas are striking examples of the improvement that may be effected in this manner; the fine rhododendrons are hybrids between the hardy *R. Catawbiense* of the southern Alleghanies and *R. Ponticum*, a greenhouse species from Asia Minor. It is a singular fact that the English hybrids, in which *R. Catawbiense* is the mother plant, are generally hardy, while the Belgian hybrids are very much less hardy for the reason that the Belgian florists use *R. Ponticum* as the seed-bearer. When a desirable form is obtained by hybridizing, it can be continued and multiplied indefinitely by means of layers, cuttings, or grafts. Hybrid plants are sometimes fertile; the progeny from them shows a tendency to revert to the one or the other parent, and in a few generations all trace of the admixture is obliterated; sometimes the progeny is too weak to bear seeds, and thus becomes extinct. More generally hybrid plants are wholly or partly sterile; the degeneration shows itself most prominently in the anthers, which fail to pro-

duce pollen; the pistil in this case will be fertilized, if at all, by pollen from either parent, and thus a reversion of its progeny to a normal form assured; sometimes the pistils are abortive also. It will be seen that while hybrids may be produced among plants in a wild state, and are often produced in cultivation, there is abundant provision against the perpetuation of a race of monsters.—Another kind of hybrid in which fertilization plays no part has recently received the attention of vegetable physiologists. There are a number of well authenticated cases in which a graft or bud has so influenced the stock in which it was inserted that the stock, even below the point of union, put out branches partaking of the characters of both stock and scion. Some of these graft hybrids, as they are called, have been propagated. An account of this kind of hybrids, as well as a very full résumé of the whole subject of hybrids, will be found in Darwin's "Variation of Animals and Plants under Domestication." See also his "Origin of Species," and E. A. Carrière's *Production et fixation des variétés dans les végétaux* (Paris, 1865).

HYDASPES, a river of ancient India. See **JHYLUM**, and **PUNJAUB**.

HYDATIDS. See **ENTROZOA**, vol. vi., p. 666.

HYDE. **I.** An E. county of North Carolina, bordering on Pamlico sound, and bounded W. by Pango river; area, about 650 sq. m.; pop. in 1870, 6,445, of whom 2,378 were colored. It has a level surface, a large part of which is occupied by pine, cypress, and cedar swamps. The products of the pine are the staples of export. The chief productions in 1870 were 21,319 bushels of wheat, 163,216 of Indian corn, 11,633 of oats, 235 bales of cotton, and 171,548 lbs. of rice. There were 378 horses, 681 milch cows, 1,484 other cattle, and 3,706 swine. Capital, Swan Quarter. **II.** A S. E. county of Dakota, recently formed, and not included in the census of 1870; area, about 1,000 sq. m. Its S. W. corner touches the Missouri river.

HYDE, Edward. See **CLARENDON**.

HYDE, Thomas, an English orientalist, born at Billingsley, Shropshire, June 29, 1636, died in Oxford, Jan. 18, 1703. He studied at Cambridge and Oxford, took orders, became librarian of the Bodleian library, succeeded Pococke in 1691 as Laudian professor of Arabic, and soon after was appointed regius professor of Hebrew. In 1678 he was made archdeacon of Gloucester. He understood Hebrew, Syriac, Arabic, Persian, Armenian, Malay, and Chinese, and was interpreter of oriental languages to the court during the reigns of Charles II., James II., and William III. The most important of his works is *Veterum Persarum et Medorum Religionis Historia* (Oxford, 1700; best ed., 1760). A complete edition of his other writings appeared at Oxford in 1767.

HYDE DE NEUVILLE, Jean Guillaume, baron, a French politician of Scottish descent, born at La Charité-sur-Loire, Jan. 24, 1776, died in Paris, May 28, 1857. He was one of the most

active agents of the Bourbons after the death of Louis XVI., and mingled in nearly all the intrigues for the subversion of the revolutionary governments. After the 18th Brumaire, in an interview with Bonaparte, he tried to persuade him to restore the Bourbons. He was charged by Fouché with being an accomplice in the infernal machine plot, but cleared himself from the accusation. He subsequently removed to the United States, settled in the vicinity of New York, became acquainted there with Gen. Moreau, then an exile, and is said to have been instrumental in persuading him to return to Europe. Early in 1814 he returned to France, and was welcomed by the Bourbons, who had just been reinstated on the throne. He was engaged in all the negotiations and transactions which took place during 1814 and 1815, and on the second restoration was elected by his native department a deputy to the *chambre introuvable*, where he was an uncompromising advocate of the most reactionary measures. In 1816 he was appointed minister plenipotentiary to the United States, and held that office till 1821, when, after being created a baron, he was recalled to France. Being ambassador at Lisbon in 1824, he cooperated in restoring to power the old king John VI., whom his son Dom Miguel had imprisoned. Thenceforth he gradually estranged himself from the ultraroyalist party. In 1828 he entered the Martignac cabinet as minister of the navy, made several improvements in the colonial system, enforced measures against the African slave trade, and favored the independence of Greece. On the breaking out of the revolution of 1830, he asserted the claims of the duke of Bordeaux to the throne, in the chamber of deputies, and resigned his seat on Louis Philippe being selected. From that period he devoted himself mainly to agriculture.

HYDERABAD. **I.** A native state of the Deccan, India, called also the Nizam's Dominions, lying between lat. 15° and 21° 30' N., and lon. 74° 40' and 81° 30' E., bounded N. by Berar, N. E. by the Central Provinces, N. W. and W. by the presidency of Bombay, and S. and S. E. by that of Madras; area, 95,337 sq. m.; pop. about 11,000,000. The surface consists chiefly of a high table land 1,800 to 2,000 ft. above the sea, several granite masses rising to an elevation of 2,500 ft. The geological formation of this region is simple. Resting on a base of granite, gneiss, and talc slate are clay, hornblende, feldspar, limestone, and sandstone; and in some parts columnar basalt is conspicuous. The principal rivers are the Godavery, flowing through the middle of the country, the Kistnah, which winds along its southern limits, and the Wurda and Paingunga in the north, all flowing in an easterly direction. The minerals comprise iron (the iron ore in the Nirmal hills being magnetic) and coal, which is found near the junction of the Godavery and Wurda. Near the Godavery are also mines of garnet, and at Partheal near Condapilly are diamond

mines, from which the treasury of Golconda was formerly supplied. The soil of the country is fertile, but not well cultivated. There is a considerable area of waste and forest lands. Wheat and cotton are the principal agricultural products; other productions are barley, rice, oil plants, cucumbers, gourds, hemp, sugar cane, tobacco, sweet potatoes, aromatic seeds, jowary (Indian millet), and bajree, a species of grain which forms the chief sustenance of the laboring classes. The principal manufactures are silks, brocades, and carpets, and in the southeast calico printing by means of wooden blocks is carried on to some extent. The chief exports are steel, cotton, and teak. The climate, owing to the elevated position of the country, is colder than is usual in this latitude. The territory is crossed by several good military roads, and the Great Indian Peninsula railway traverses the eastern and southern parts of the country. Branch lines are projected from this main line to the city of Hyderabad, and from Hyderabad to Masulipatam on the Madras coast. The government is Mohammedan, but nearly nine tenths of the people are Hindoos.—Hyderabad was anciently subject to the rajahs of Telingana and Bijanagur. It was erected into a separate kingdom in 1512 by a Turkish adventurer, and in 1687 became a province of the Mogul empire. Azof Jah, an officer of the court of Delhi, who in 1719 governed this and the five other provinces of the Deccan with the title of Nizam ul-Mulk ("regulator of the state"), made himself independent. On his death in 1748 the succession was disputed by his son Nazir Jung, whose cause was espoused by the English, and his grandson Mirzapha Jung, who was favored by the French. The latter finally triumphed, and governed under the direction of the French commander Dupleix until he was put to death by some Patan chiefs. During a period of anarchy which followed, the French and English supported rival claimants for the sovereignty. Nizam Ali, who came to the throne in 1761, ravaged the Carnatic, but was overpowered by a British force, and induced to sign a treaty in 1766 which gave to the East India company the Northern Circars. The English bound themselves to maintain a military force for the nizam's protection. In the war between the British and Hyder Ali, however, the nizam sided with the sultan of Mysore, but in that with Tippoo Saib he formed

an alliance with the company and the peishwa, and received a share of the spoils of victory. The accession of territory which he then obtained he subsequently ceded to the British in lieu of payment for the support of the British contingent. On the conclusion of the first Mahratta war in 1804 his dominions were again enlarged. The misgovernment of the country under the successors of Nizam Ali plunged Hyderabad deeply in debt. The East India company was at one time creditor to the amount of £500,000 or £600,000, and in liquidation they accepted a cession of the province of Berar, part of the revenues of which were to be devoted to the support of the subsidiary native force known as the nizam's contingent. The nizam remained true to the British during the mutiny of 1857-'8, and his dominions were little disturbed except by marauders. II. A town, capital of the Nizam's Dominions, situated on the river Mussi, about 800 m. N. N. W. of Madras; pop. variously estimated at

British Residency in Hyderabad.

80,000, 120,000, and 200,000, a large majority of whom are Mohammedans. It is a weakly fortified town, crowded with buildings, some of which are large and imposing, having numerous mosques, and surrounded by gardens of remarkable beauty. The British residency is a magnificent edifice on the opposite side of the river, connected with the town by a stone bridge. In the neighborhood there are large water tanks, one of which is 20 m. in circuit. A large British garrison is maintained at Hyderabad, and there is an extensive military cantonment at Secunderabad, a few miles N. E. of the town. The celebrated city of Golconda is 7 m. distant to the northwest.

HYDER ALI, sultan of Mysore, born in Dinavelli, Mysore, about 1718, died Dec. 7, 1782. He was of Arabian descent, and son of a petty chief. Entering the service of the rajah of Mysore in 1749, he rose in the course of ten years to be

commander of the forces, and, having thus the power in his own hands, set aside the rajah with a pension of three lacs of rupees, and took possession of the sovereignty. The East India company, becoming alarmed at his increasing power, formed an alliance with the Mahrattas and the nizam of the Deccan against him; but Hyder not only gained over the nizam to his side, but for two years waged vehement war on the British. By a series of skilful manœuvres he managed to draw their force to a distance from Madras, and then at the head of 6,000 horsemen rode 120 m. in three days and appeared before the city. The outlying country being at his mercy, the government of the presidency was compelled to come to terms, and Hyder agreed to a treaty of which the principal feature was that the British should form an alliance with him in his defensive wars. In 1770, the Mahrattas having invaded his dominions, he applied to the British for their promised aid, but could obtain from them nothing more than neutrality. By the year 1778 he had recovered from the disadvantages their defection had caused him. Being once more threatened by the same warlike people, he again invited British assistance, but with a like result. Incensed by this conduct, he formed an alliance with the Mahrattas and the nizam, and in 1780 invaded the British territory of the Carnatic, which he ravaged with fire and sword, capturing many of the strong places, but avoiding battle in the open field. The desolation he brought on the country during the two years' war was such that the British force, and even the city of Madras, were in danger from famine. This war elicited a remarkable display of military talent by the British general Sir Eyre Coote on the one side, and by Hyder and the French officers, of whom he had many in his service, on the other. The Mysore leader had already rejected terms of adjustment offered by Lord Macartney, the governor of Madras, when he died, and was succeeded by his son Tippoo Saib.

HYDRA. See HERCULES.

HYDRA. I. An island in the Grecian archipelago, off the E. coast of the Morea, belonging to the nomarchy of Argolis and Corinth; greatest length N. E. to S. W. about 12 m., greatest breadth 3 m.; pop. about 20,000. Its surface is rocky, sterile, and mountainous. The inhabitants are esteemed the best sailors of Greece. **II.** A town, capital of the island, situated on a barren rugged height on the N. W. shore; pop. in 1870, 7,428. The streets are steep and uneven, and the houses substantially built. The manufactures are silk and cotton stuffs, soap, and leather. The harbor is formed by a deep bay, but is neither spacious nor well sheltered. During the war of the revolution Hydra was a place of general refuge for people from all parts of Greece.

HYDRABAD, a town of British India, in the province of Sinde, situated on an eminence belonging to the Gunjah hills, 4 m. E. of the

E. bank of the Indus; pop. about 20,000. Part of it is built on an island 15 m. long, which is formed by the Indus and an offset of that stream called the Fulailee. It is defended by a fortress of imposing appearance but no great strength, and has manufactures of matchlocks, swords, spears, and shields, and of ornamental silks and cottons. The town is connected with Kurrachee on the Arabian sea by a railway 120 m. long. Hyderabad was formerly the residence of the chief amirs of Sinde, who governed the southern and principal part of the country. A victory was gained over a Sindian force near here by Sir C. Napier, Feb. 24, 1843.

HYDRANGEA (Gr. *ὕδωρ*, water, and *ἄγγος*, a vase), a genus of shrubby plants, to which the name was applied for no obvious reason, belonging to the natural order *saxifragaceæ*, and natives of Asia and of North America. The species best known (*H. Hortensia*), the common hydrangea, was introduced into England from China in the year 1790 by Sir Joseph

Garden Hydrangea (*H. Hortensia*).

Banks. Commerson, wishing to honor his friend Mme. Hortense Lapeaute, called the plant *Lapeautia*; but thinking the compliment not sufficiently pointed, he changed the name to *Hortensia*, by which it is still known in France; when it was found to belong to the old genus *hydrangea*, Commerson's generic name was retained for the species; it is often incorrectly written *hortensis*. It is a smooth, dwarf, vigorous shrub, with opposite, coarsely toothed, oval leaves, and bears immense globular clusters of sterile flowers, which are white, pink, or blue, according to the nature of the soil. Cuttings of the wood or of the growing stems will root without difficulty. The hydrangea delights in an unlimited supply of water, fading at once on its being withheld. There is a variety with variegated foliage, nearly all silver white, which is fine in the greenhouse, but does not endure our hot sun. Specimens are mentioned in England of 30 ft. circumference,

and producing on a single clump more than 1,000 heads or corymbs of flowers. In the United States, even so far north as Boston, it will survive the winter if slightly protected by the stems being covered. The wild hydrangea (*H. arborescens*, Linn.) is a shrub 4 to 6

Oak-leaved Hydrangea (*H. quercifolia*).

ft. high; its flowers, which are borne on flat cymes, are white or yellowish, and usually all fertile, but sometimes with a row of sterile ones around the margin; the species ranges from Pennsylvania southward. The oak-leaved hydrangea (*H. quercifolia*) was first discovered by Bartram in Georgia; it was carried to England in 1803, and is the finest North American species; it has deeply lobed, oak-like leaves, and fine large corymbs of nearly white flowers, which change afterward to purple. In the gardens at the north is often seen the snowy-leaved hydrangea (*H. nivea*, Mx.), a shrub from 6 to 8 ft. high, with large leaves of a silvery whiteness beneath, and flowers in terminal cymes, having a few showy, white, sterile florets enclosing many small, green, fertile ones; it grows in the upper part of Georgia and the Carolinas. Within a few years several fine hydrangeas have been introduced from Japan, some of which, though they have received specific names, are varieties of *H. Hortensia*, while others are distinct; preëminent among these is *H. paniculata grandiflora* (sometimes called *H. deutzifolia*), which is one of the finest hardy shrubs in cultivation; it produces an oblong panicle, often a foot long, of sterile flowers, which are at first white, then gradually turn pink, and by the time frost comes they are brownish red.

HYDRASTIS. See PUCCOON.

HYDRATES (Gr. ὑδωρ, water), compounds containing water, or its elements in the proportion to form water. Thus lime (oxide of calcium) slaked with water forms a chemical combination with a portion of this, and falls to a white

powder, which is a hydrate of lime. Hydrate of potassa is a combination of potassa and water, and is permanent even when exposed to high temperature. Common oil of vitriol is also a chemical combination of water and sulphuric anhydride.

HYDRAULIC RAM, a machine for raising water by employing its own momentum, acquired by a fall, a portion of the water only being raised. The accompanying diagram, fig. 1, will serve to explain its action. An impulse pipe, H, leads from a cistern or reservoir, C, and has a fall depending on the amount of impulse required, and corresponding with the other parts of the machine, and on the height the water is required to be raised. The lower end of this impulse pipe turns up at A, where there is a large valve, usually conical and opening downward. This valve is of such a weight that the simple pressure of the water in the cistern and pipe, or the head, will not raise it, a certain degree of momentum being required for that purpose. When the valve is open the water rushes through it and soon attains this required momentum, and the valve rises and shuts against its seat. The motion of the water in the end at A is arrested, but not entirely so in that portion of the pipe between H and the cistern, for the impulse opens the valve B and forces water into the bell-shaped chamber D, and eventually into the delivery pipe E. When the impulse of the water flowing through the valve B becomes less than the pressure upon it, the valve closes and prevents the water which has passed through from returning. The time of this flow is very short, because the arrest of motion of the water in the end of the impulse pipe so reduces the force exerted against the impulse valve that it falls after a brief interval, when the water again rushes out and relieves the pressure at B. But it soon acquires sufficient momentum to again raise the impulse valve, when the shock is repeated, and the acquired momentum again expends itself principally against the valve B, and the

FIG. 1.—Hydraulic Ram.

water ascends into the air chamber and delivery pipe. The use of the air chamber is obviously to produce a constant pressure in the pipe E, as nearly as practicable, and to relieve it from the sudden shock which would otherwise be caused by the shutting of the valve B.

The expenditure of force in this machine is obtained by multiplying the amount of water discharged at A into the head, or height of water in the cistern above the valve A. The economy of force is found by multiplying the amount of water delivered by the pipe E into the height to which it is raised. The proportion in good rams is from 60 to 70 per cent. The head of water should be from 4 to 6 ft. for raising water vertically 30 ft. There is a difference of opinion in regard to the proportional increase of head to increase in height of the delivery pipe, and machines of different modes of construction will require variation in this particular. The height of head is, however, practically restricted in consequence of the wear and strain produced by the shock when the head is great. A practical difficulty in the machine is to preserve the necessary quantity of air in the air chamber. This is constantly being absorbed by the water, so that in time its volume becomes too small to yield sufficient elasticity. The difficulty is obviated to a great degree by the application of what is called a shifting valve, opening inward at G. There is a moment of time after the shutting of the impulse valve when there is in certain parts of the machine a diminution of internal pressure to a degree below that of the pressure of the atmosphere. During this moment a bubble of air will enter at G and ascend into the air chamber, but it is difficult so to regulate the supply that it will not be necessary to remove the air chamber and introduce a fresh supply of air. In large European machines there is often placed at B an inner air chamber with two valves at its base, suspended by hinges and opening laterally. The impulse pipe may be straight, and inclined as shown in the figure, or have a vertical and a horizontal limb; or it may be curved. There are several practical points in regard to its size and length which should be observed in the erection of the ram. In general, it may be stated that if the impulse pipe is very wide and short, it will not maintain a sufficient impulse to lift the water against great pressure in a long delivery

FIG. 2.—Whitehurst's Machine.

pipe, because of the tendency to a reactionary movement of its contents, which is prevented by the resistance offered by a longer and smaller pipe. The invention of the hydraulic ram is ascribed to the elder Montgolfier, and its improvements to his son. The principle,

however, was previously employed by John Whitehurst of Cheapside in a machine constructed by him in 1772, an account of which was published in the "Philosophical Transactions" in 1775. Fig. 2 is a representation of Whitehurst's machine, and it will be seen that the principal difference between it and Montgolfier's ram is that it has a stopcock in place of the automatic impulse valve. Leading from the cistern H is a long pipe, A E, much longer in proportion than is represented in the figure, which is the impulse pipe. Its contents receive momentum from the opening of the cock B, which is several feet below E. When sufficient force has been obtained the cock is shut, and the column of water in A B is urged by its momentum along the direct branch of the pipe G, through its depressed extremity D, into the bottom of the air chamber C. This part of the pipe contains a valve opening toward the air chamber, corresponding to the one in Montgolfier's machine. F is the lower section of the delivery pipe. The principle of action is precisely the same in the two machines, and the explanation of the ram will answer for that of Whitehurst's machine.

HYDRAULICS. See HYDROMECHANICS.

HYDROCEPHALUS. See BRAIN, DISEASES OF THE, vol. iii., p. 197.

HYDROCHLORIC ACID, or **Chlorohydric Acid,** a gaseous compound of one equivalent of chlorine and one of hydrogen (HCl), of combining proportion 36.5, long known in its aqueous solution by the names of muriatic acid, marine salt, and spirit of salt, in reference to its being prepared from sea salt (*urias*). Priestley first obtained it as a gas in 1772, and Gay-Lussac, Thénard, and Davy long afterward showed that it consists of equal volumes of chlorine and hydrogen, and occupies the same space as the gases which produce it. Its elements mixed together slowly combine by the action of the light, but instantly with explosion if exposed to the direct rays of the sun, or if an electric spark is passed through the mixture, or a lighted taper is brought in contact with it. The gas is obtained by adding concentrated sulphuric acid to common salt placed in a retort, and collecting over mercury. The chlorine of the salt (chloride of sodium) unites with the hydrogen of the sulphuric acid, producing hydrochloric acid and acid sulphate of soda; or, by symbols, $\text{NaCl} + \text{H}_2\text{SO}_4 = \text{HCl} + \text{NaHSO}_4$. The gas is colorless, but escaping in the air it instantly unites with moisture present, and forms a white cloud. It has a strongly acid taste and a pungent odor. Taken into the lungs it is irrespirable, but when diluted with air is not so irritating as chlorine. It neither supports combustion nor is itself inflammable. Under a pressure of 40 atmospheres, at 50° F., it is condensed into a liquid of specific gravity 1.27, which dissolves bitumen. The density of the gas is 1269.5, air being 1000. Its affinity for water is such that it can be kept only in jars

over mercury. If a piece of ice be introduced into a jar containing the gas, the ice is instantly liquefied, and the gas disappears. If the jar be opened under water, the water rushes up as into a vacuum. Water at 40° F. absorbs nearly its own weight, or about 480 times its bulk of hydrochloric acid gas, increasing in volume about one third, and acquiring a density of 1.2109; at this strength it contains nearly 43 per cent. of acid. The aqueous solution is the form in which the acid is commonly known. It is of various degrees of strength, the strongest readily obtained having 6 equivalents of water to 1 of acid, 40.66 per cent. of real acid, and being of specific gravity 1.203. This loses acid by evaporation, coming, according to Prof. Graham, to 12 equivalents of water to 1 of acid, this containing 25.52 of real acid, and being of specific gravity 1.1197. When reduced by distillation till it changes no more, it contains 16.4 equivalents of water and 20 per cent. of real acid, and is of specific gravity 1.0947. The following table by Mr. E. Davy gives its strength at different densities:

Sp. gr.	Quantity of acid per cent.	Sp. gr.	Quantity of acid per cent.
1.21.....	42.43	1.10.....	20.20
1.20.....	40.40	1.09.....	18.18
1.19.....	38.83	1.08.....	16.16
1.18.....	36.86	1.07.....	14.14
1.17.....	34.84	1.06.....	12.12
1.16.....	32.82	1.05.....	10.18
1.15.....	30.80	1.04.....	8.08
1.14.....	29.28	1.03.....	6.06
1.13.....	26.26	1.02.....	4.04
1.12.....	24.24	1.01.....	2.02
1.11.....	22.22		

An approximate result is obtained by multiplying the decimal of the specific gravity by 200.—The pure concentrated acid is colorless, and fuming when exposed to the air. It is conveniently used for most purposes diluted to a specific gravity of about 1.1, at which it does not fume. Though powerfully acid, it is not so corrosive as sulphuric acid. It is decomposed by substances which yield oxygen freely, as the manganese dioxide, and is thus made to furnish chlorine gas, its hydrogen combining with the oxygen of the metallic oxide. Nitrate of silver, AgNO₃ (old AgO,NO₃), detects its presence by the formation of a white curdy precipitate of chloride of silver, AgCl, which is soluble in ammonia, but not in nitric acid.—Ingredients used for preparing hydrochloric acid either upon a large or small scale are common salt, sulphuric acid, and water. Different proportions are adopted, the most usual being equal weights of concentrated acid and of salt, or in the large way 6 parts of salt to 5 of acid, being an equivalent of each, to which 5 parts of water are usually added. The acid mixed with about half water is poured when cool upon the salt contained in a large retort, and the remainder of the water is placed in the vessel serving as a condenser to receive the gas. Heat is applied to the retort, and the acid gas distils over; the water in the condenser

allows none of it to escape, so long as it is kept cool and is not saturated. The aqueous solution obtained is of specific gravity about 1.17, and contains 34 per cent. of dry acid. The residuum is common sulphate of soda or Glauber's salt. The acid is so cheaply prepared in large chemical works, that it is seldom made in the laboratory. It is an incidental product in the manufacture of carbonate of soda, and was formerly allowed to go to waste. The commercial article is often contaminated with iron, which gives it a yellow color, though this is sometimes owing to organic matter, as cork or wood. Sulphuric acid is almost always present in it, and sometimes free chlorine and nitrous acid. Sulphurous acid, H₂SO₃, has also been found, to the amount of 7 to nearly 11 per cent. Sulphuric acid is detected by the formation of a white precipitate of sulphate of baryta, produced when chloride of barium, BaCl₂, is added to a diluted portion of acid. Traces of sulphurous acid are detected by a mixture of perchloride of iron and ferrocyanide of potassium, Prussian blue being formed by the reducing action of the acid on the mixture. Arsenic and chloride of lead, PbCl₂, may sometimes be detected by a current of sulphuretted hydrogen, H₂S (PbCl₂ + HS₂ = 2HCl + PbS). The common method of purifying is to dilute, add chloride of barium, and distil.—Hydrochloric acid is largely employed in the arts, especially as a solvent for mineral substances. In combination with nitric acid it makes the *agua regia*, used for dissolving gold and platinum. It is used to furnish chlorine in the preparation of bleaching and disinfectant salts, and in the production of sal ammoniac; and is employed to extract gelatine from bones. When neutralized with basic oxides, it does not combine as an acid with these, but gives its hydrogen to their oxygen, and its chlorine unites with the metallic base of the oxide.—In medicine hydrochloric acid may be employed with advantage, largely diluted, to assist the process of digestion, which it does by replacing the deficient portion of the normal acid and of the gastric juice. When administered with pepsine it forms a sort of artificial gastric juice. It has also been employed as a tonic in various diseases, and as an ingredient of gargles, when sufficiently diluted. The strong acid may be used as an escharotic. It is much less corrosive than sulphuric acid. When poisoning has occurred from swallowing the strong acid, it should be neutralized by magnesia or soap, and the case then treated as other kinds of corrosive poisoning are. The principal indications for the therapeutic administration of hydrochloric acid are to be found in calculous affections, in certain forms of dyspepsia, in typhus and typhoid fevers, and in aphthous affections of the mouth and stomach. It may be given in the dose of from 10 to 30 drops three or four times a day, freely diluted with water. Its local application in cases of ulcerated, putrid, and diphtheritic sore throat has often been attended with the happiest results.

HYDROCYANIC ACID, or **Prussic Acid** ($\text{HCN} = \text{HCy}$; chemical equivalent 27), was first obtained in its aqueous solution by Scheele in 1782, who described it correctly as consisting of hydrogen, carbon, and nitrogen; but the true nature of the compound was determined by Gay-Lussac 30 years later, who first obtained the anhydrous acid. This is a colorless, inflammable liquid, possessing a strong odor, which is recognized in peach blossoms; but when exhaled from the pure acid it is so powerful as to cause immediate headache and giddiness, involving the most serious consequences to life itself. The vapor is so remarkably volatile, that a drop of the acid congeals upon a piece of glass by the rapid evaporation of a portion of the liquid. It boils at 80° , and freezes at 5° into a fibrous mass. At 45°F . its specific gravity is 0.7058. Its taste (a hazardous test) is acrid and bitter like that of bitter almonds. Its acid properties are feeble; the faint red tinge it imparts to litmus paper soon disappears; and it fails to decompose salts of carbonic acid. It exists in parts of many plants, as the kernels of peaches, almonds, plums, &c., and in the leaves of the peach, laurel, &c. It is also generated in the processes contrived for extracting it from various vegetable matters. The chief source of the acid, however, is the blood, hoofs, horns, and tissues of animals, which are made to furnish cyanogen to potassium on being ignited with carbonate of potash, and the cyanide thus obtained and other cyanides of the same derivation are employed to furnish the cyanogen for the acid. Its coloration in Prussian blue gave it the name of Prussic acid. Many methods have been devised for preparing the anhydrous acid. The cyanide of mercury has been decomposed together with hydrochloric acid, thus producing chloride of mercury and hydrocyanic acid; and sulphuretted hydrogen and also diluted sulphuric acid have by suitable processes been substituted for the hydrochloric acid. But the aqueous solution or medicinal acid is commonly prepared direct by some one of the numerous processes of the pharmacopœias. The following, adopted in the United States, is recommended for its simplicity and convenience: Of cyanide of silver $50\frac{1}{2}$ grains are dissolved in 41 grains of hydrochloric acid diluted with a fluid ounce of distilled water; the mixture is shaken in a well stopped phial, and the clear liquor, poured off from the insoluble matter which subsides, is kept in tight bottles excluded from the light. Single equivalents of the acid and cyanide salt are employed; and by their mutual decomposition hydrocyanic acid is obtained in solution, and chloride of silver falls as a precipitate. By this method the acid may always be prepared as wanted; a matter of no little importance in its medicinal applications, in consideration of its liability to decompose spontaneously, and its consequent uncertain composition and strength. The aqueous solutions prepared by the different processes

adopted are not uniform in their proportions of anhydrous acid; but their strength ought not to exceed 3 per cent. of pure acid. Various methods are given in the chemical books of ascertaining this strength and the degree of purity. Sulphuric and hydrochloric acids are the most common foreign bodies present. The quantity of real acid is usually determined by the weight of cyanide of silver precipitated on adding nitrate of silver. By the United States formula 100 grains of pure acid must accurately saturate 12.7 grains of nitrate of silver dissolved in distilled water, and produce a precipitate of cyanide of silver, which, washed and dried at a temperature not exceeding 212° , shall weigh 10 grains and be wholly soluble in boiling nitric acid. If a residue remain, it is chloride of silver, indicating the presence of hydrochloric acid in the original. Sulphuric acid would be indicated by a precipitate formed on adding chloride of barium to a portion of the acid.—Hydrocyanic acid is well known as one of the most powerful of poisons, destructive to vegetable as well as animal life. Seeds immersed in it lose their germinating power, and the stems of sensitive plants lose their peculiar property by its application. Small doses of hydrocyanic acid give rise to a bitter taste, a tingling in the throat, a feeling of warmth in the stomach, and an increased secretion of saliva. If the dose is increased, there are in addition headache, dizziness, confusion, drowsiness, and sometimes nausea and labored breathing. After the long continued use of small doses the pulse becomes less frequent. As the dose is increased the symptoms above mentioned increase in intensity, especially the dyspnoea, while the pulse becomes frequent and small. Consciousness may be completely lost, the pupil dilated, and convulsions occur, and yet recovery take place. Fatal cases occur with aggravation of these symptoms, except when death takes place so rapidly that no symptoms are developed beyond sudden loss of consciousness, a short period of labored breathing, disappearance of the pulse, and collapse. When continuously applied externally, hydrocyanic acid lessens the irritability of the sensitive nerves. It is used in medicine to diminish pain and irritation; in some affections of the stomach to check vomiting; and in chest affections to allay cough, especially of a spasmodic character. Oil of bitter almonds has been used to produce the effect of hydrocyanic acid, but the amount of acid contained therein is so variable that it is an uncertain preparation. When poisoning takes place, death often approaches so rapidly as to preclude the employment of any efficient treatment. But if the heart is still beating, stimulants, especially ammonia, should be very cautiously applied. Cold affusion may also act as an excitant, and artificial respiration may sustain life long enough for a portion of the poison to be eliminated, and life saved. The subcutaneous injection of atropia has also been

proposed, but has not been proved to be of much value as an antidote. After death and before decomposition has taken place, the presence of hydrocyanic acid is rendered apparent in the blood vessels and also in the brain by its peculiar odor. To obtain the acid, the contents of the stomach should be washed with distilled water and filtered, and the filtrate distilled in a water bath. The product may then be subjected to the various tests given in the chemical works. The therapeutic value of hydrocyanic acid is limited chiefly to a few nervous affections of the stomach, to the vomiting of pregnancy, and to whooping cough and spasmodic derangements of the respiratory organs. Only the dilute form is used medicinally, of which the dose varies from two to five or six drops.

HYDRODYNAMICS. See HYDROMECHANICS.

HYDROFLUORIC ACID. See FLUORINE.

HYDROGEN (Gr. *ὕδωρ*, water, and *γεννάειν*, to produce), an elementary gaseous body, named from its property of forming water by combining with oxygen. Its symbol is H; chemical equivalent 1; weight compared with air 0.06926; 100 cubic inches weigh under ordinary pressure and temperature 2.14 grains, being 16 times less than an equal volume of oxygen, and 14.4 times less than air. One litre of hydrogen gas at 0° C. and 760 mm. pressure weighs 0.08936 gramme. It was known near the close of the 17th century, and was termed inflammable air from its burning with a flame; it was also called phlogiston, from the supposition of its being the matter of heat. Its real nature was first described by Cavendish in 1766. The gas is not found uncombined, but is readily obtained by decomposing water, of which it constitutes about one ninth by weight, the remainder being oxygen. This process is effected very much as metallic oxides are decomposed, some substance being presented to the compound which has a strong affinity for the oxygen, and combining with it liberates the hydrogen or other element. The vapor of water passed through an iron tube filled with iron shavings and kept at a red heat is thus decomposed, the oxygen uniting with the iron, and the hydrogen escaping. The common method of preparing the gas is to place some bits of zinc in oil of vitriol or sulphuric acid diluted with five or six times its bulk of water. Chemical action immediately takes place, and the zinc is dissolved with effervescence, owing to the bubbles of hydrogen separating from the liquid. The reaction is represented by the formula $Zn + H_2SO_4 = ZnSO_4 + H_2$. With an ounce of zinc there may be obtained 615 cubic inches of hydrogen. A common flask answers very well for the apparatus, by inserting a bent tube through the cork for the exit of the gas, and a straight tube, terminating above in a small funnel, and reaching below the cork nearly to the bottom of the flask, at least so as to be covered by the liquid. Through this tube the acid is poured

in as required, the zinc and water being first introduced. The sulphur and carbon which are present in almost all zinc appear in the hydrogen as traces of sulphuretted hydrogen and carbonic acid. They may be separated by agitating the gas with lime water. When pure, hydrogen has neither taste, smell, nor color. It is destructive to animal life when inhaled for a short time, and extinguishes a burning taper plunged into it. Yet it is itself highly combustible, burning with a faint bluish yellow flame at its contact with atmospheric air or oxygen; and when mixed with proper proportions of ether and ignited by flame, an electric spark, or a glass rod heated hardly to redness, its combustion is instantaneous and explosive. A piece of spongy platinum introduced into the mixture also causes combustion to take place. The most violent effects are produced by a mixture of two volumes of hydrogen and one of oxygen. The only product of the combustion of hydrogen is water. The gas is made to enter into combination with the oxygen of the air, producing heat sufficient to cause its ignition, by directing a jet of it upon a piece of spongy platinum, or even upon a perfectly clean surface of sheet platinum. The metal becomes red hot, the gas ignites, and thus a light may be instantaneously obtained. A little apparatus was devised for this purpose by Prof. Döbereiner, which would be an excellent means of obtaining a flame in the absence of the cheap matches in common use. Though the flame of hydrogen is very slightly luminous, a bright light is emitted from the heated platinum; and an apparatus based on this principle has been applied to purposes of illumination in the place of ordinary gas lights. Such lights were at one time in practical use in France and England. The hydrogen was produced by the decomposition of water, effected by passing its vapor over incandescent charcoal contained in a tube; some carbonic oxide and carburetted hydrogen were generated, which burned with the hydrogen, the jet of mixed gases being directed against a basket constructed of fine gauze of platinum, which became intensely hot and highly luminous. Hydrogen produces intense heat by its combustion, taking up more oxygen than is required by the same weight of any other combustible. It is this property that has led to its application in the oxyhydrogen blow-pipe for melting the most refractory substances. (See BLOWPIPE.) The levity of hydrogen early suggested its use for filling balloons. The quantity required to fill one of the capacity of 2,000 cubic feet would weigh only 10.57 lbs., while the same volume of air would weigh 153.26 lbs., giving an ascensional power of 142.69 lbs. Illuminating gas is heavier, but is commonly used instead of hydrogen only on account of its greater cheapness. Hydrogen is so subtle and penetrating a gas that it passes with facility through paper and also through gold and silver leaves. A stream of the gas directed against one side of the leaf may be ignited on the

other. Hydrogen combines with one equivalent of oxygen to form hydrogen monoxide or water; with two equivalents to form the dioxide or oxygenated water, a liquid discovered by Thénard in 1818, and now prepared by chemists for medicinal purposes; also with one equivalent of nitrogen to form ammonia; and with one of chlorine to form hydrochloric acid. From his researches on the occlusion of hydrogen by palladium, Prof. Graham was led to infer the existence of an alloy of palladium and hydrogen gas condensed to a solid form, to which he gave the name of *hydrogenium*. Assuming that the hydrogen enters into the combination with the density which it would exhibit if solidified in the free state, he calculates, from the observed density of this so-called alloy of palladium and hydrogenium, and of similar alloys containing in addition gold, silver, or nickel, that the density of this hypothetically solidified hydrogen varies between the limits 0.711 and 0.7545; mean, 0.733. The presence of hydrogen in the atmosphere of the sun and in the planets has been shown by spectrum analysis. On the sun four lines are attributed to hydrogen.

HYDROGRAPHY is the science which, by representation of the figure of the bottom of the ocean and its tributaries by means of soundings, by observations of tides and currents, and by investigations of the winds and their action and of the law of storms, aims to diminish the risk attending the navigation of dangerous waters. The results of these investigations are shown upon charts, which give the outlines of the coasts and harbors, the depths of water in the navigable channels, the rocks and shoals with the soundings upon them, and various tidal and magnetic information. In the course of the investigations specimens of the bottom are also obtained by apparatus attached to the sounding lead; and the temperature of the water is frequently taken as an additional guide to determine the mariner's position. By such sea charts as are now prepared and published by the English and French hydrographic offices and by the coast survey of the United States, the risks attending navigation have been greatly diminished. (See **COAST SURVEY**.) Hydrography, as it now exists, belongs to modern times, although various rude attempts at hydrographic examinations and the construction of sea charts were made in early times. The invention of charts for mariners is commonly ascribed to Henry the Navigator (1394-1460), although earlier ones exist. Of necessity such were rude and imperfect, the size and even the true shape of the earth being then unknown, the log for measuring nautical miles not in use, the only instrument for determining latitude being the sea astrolabe, and none existing for determining the longitude. Little was accomplished through national instrumentality toward the improvement of our knowledge of the sea and its tributaries until the middle of the 18th cen-

tury; what little was known being the result of the enterprise of individuals, such as Columbus, Cabot, Drake, and other navigators. The researches of Capt. James Cook of the English navy, which were begun at Quebec in 1759, when he was master of the frigate *Mercury*, and were continued for about 20 years, may be considered as the commencement of a new era in hydrography. (See **COOK, JAMES, and DES BARRES**.) The success of the English captain excited the rivalry of the French; and in 1785 La Pérouse was placed in command of an expedition consisting of two frigates, with a corps of scientists, and sent to continue the work which Cook's untimely fate had left unfinished. They were never heard from after their departure from Botany bay; but La Pérouse had sent home from there duplicates of the journals and charts of his discoveries up to the date of his arrival. D'Entrecasteaux's unsuccessful expedition in search of him in 1791 gave rise to a text book on marine surveying by his navigating officer, Beautemps-Beaupré, published as an appendix to the narrative of D'Entrecasteaux's voyage (1808). This, with the exception of Alexander Dalrymple's "Essay on the most Commodious Method of Marine Surveying" (1771), was the first treatise published in a practical shape. About the time of its publication Beautemps-Beaupré took charge of the survey of the French coast, and trained a corps of hydrographers, who formed the nucleus of a body of scientific engineers to be furnished to future expeditions for surveying and exploration. Spain has also done a great deal for hydrography, although in a more indirect way. The legal provision for the examination of officers of the mercantile marine as to their competency to navigate a vessel, before promoting them, has given a high reputation to its merchant service; and the nautical information obtained from that source has been found exceedingly valuable. Her example has of late years been followed by almost every nation having much commerce. But in our own times, with improved instruments, trained professional hydrographers, and liberal appropriations of money and men, hydrography has become a recognized branch of public works, and the knowledge of it an absolute necessity to the complete seaman. Reconnoissances of large extents of coast have been made by men trained to the practice of the science, with such success as to be scarcely capable of correction by the results of detailed surveys. In the latter the aid of geodesy (by which the positions of points on shore are accurately determined) is called in; and no such examination is considered complete or accurate unless it depends upon triangulation. (See **COAST SURVEY**, vol. iv., p. 757.) Great Britain, France, Spain, the United States, and other nations have now their hydrographic offices as established branches of government; and under the direction of these departments close and accurate surveys are made of the

home coasts, and their surveying vessels frequent all parts of the globe, and penetrate seas hitherto almost unknown, mapping the limits of harbors, determining with precision the geographical position of headlands and entrances, and of rocks, shoals, and sands, many of them hitherto unknown. In this science England is far in advance of all other nations. Not content with a most complete and admirable survey of her own coasts, she has extended her work to all of her possessions and to the coasts of foreign nations. Many eminent surveyors are numbered among her naval officers; but it is probable that few have done so much or displayed so much zeal and devotion to the science as the late Admiral Beaufort, so long at the head of the hydrographic office of the admiralty. His surveys were sometimes actually carried on at his own expense. Much importance is attached to the results expected from the scientific cruise of the British ship *Challenger*, which at the present time (1874) is engaged in a voyage around the world, probably the most important of its kind ever undertaken. She carries a large number of men familiar with almost all the branches of science and art, whose labors, it is hoped, will be productive of much information in natural science and in marine surveying and deep-sea dredging. Although surpassed by England in the number and completeness of her foreign surveys, the hydrographic work on our own coasts is unequalled for accuracy and rapidity of execution. Under the charge of the coast survey of the United States it has progressed in company with the trigonometrical and topographical work of that service; and it is safe to assert that the completed charts of the coast and the various harbors stand alone in the annals of surveying for beauty of execution, accuracy, and completeness of detail. A large corps of skilled professional hydrographers are constantly employed prosecuting the surveys of the numerous harbors on the Atlantic, Pacific, and gulf coasts; and others are engaged in deep-sea explorations along the course of the Gulf stream, in the gulf of Mexico, and on the coasts of California and Oregon. These deep-sea expeditions have been especially useful in determining the routes suitable for submarine cables, several of which have been laid over lines previously sounded and surveyed by officers belonging to the coast survey. One of the most successful hydrographic expeditions of modern times was that undertaken between 1851 and 1853 under the auspices of the coast survey of the United States, by Lieut. (now Rear Admiral) James Alden of the navy, in the schooner *Ewing* and steamer *Active*. More than 1,300 m. of the Pacific coast was explored, from lat. $32^{\circ} 30'$ to $48^{\circ} 20' N.$, and the geographical positions of all the prominent headlands and of the entrances to the harbors were determined by astronomical observations, from the southern boundary of the United States to the strait of Fuca; lines of

soundings were carried along the coast throughout its entire length, and hydrographic reconnaissances made of most of the harbors, with accurate views of the different entrances and of prominent points on the coast; and subsequent careful detailed surveys, based upon accurate geodetic determinations, have failed to change the results of this work in any important particular. The immediate result of this reconnaissance was the publication of a chart of the Pacific coast for the use of mariners, and subsequently of a marine directory, which has since been elaborated and published as a "Coast Pilot of the Pacific Coast of the United States."—The method of hydrographic surveying, as now practised both in this country and in Europe, is as follows: 1. *Reconnaissance*, as, for instance, the hydrographic survey of a harbor on a foreign coast, or any place where accurate geodetic information cannot be obtained. The hydrographer, obliged himself to make all the determinations of points on shore and the outlines of the coast, applies the principles of geodesy and topography, but of course in a comparatively rude manner. A base line may be measured, if on land, in the ordinary way; but if the working ground is so far from shore as to render points on shore useless (as is sometimes the case in surveys of shoals off a low and flat coast), or if the coast is occupied by an enemy, a base line is sometimes measured by anchoring a boat at each end of it, and noting the interval between the flash of a gun fired from one boat and the report as heard at the other. But this very rude method is only admissible where no other is possible. Where the surface to be surveyed is small, good results have been obtained from a base line measured by a cord, the two ends being marked either by boats or buoys. Signals are erected at each end of the base line and on prominent points along the shore, the latter being determined by horizontal angles measured from each end of the base line. Not only the angle between each end of the base and each signal is measured, but the angles between the different signals themselves; and the triangles thus formed are either computed by trigonometry or platted by intersections upon the chart. The latitude and longitude of some prominent points are also determined. The outlines of the coast or harbor are drawn between intermediate points determined by horizontal angles, and the chart is then ready for plating the sounding lines. Next, a tide gauge is erected. This is generally a plain staff, graduated to half feet; and by continuous observations of the rise and fall of the tides, and of the times of high and low water, the hydrographer obtains an approximate establishment for the port, and also the means of correcting his soundings for the rise of the tide, which is called "reducing them to the level of low water." The shore line having been rudely determined, and such natural and artificial features mapped as may be considered neces-

sary, a boat is started from any point in the harbor to run the lines of soundings. The boat is steered on a certain course, and soundings are taken at intervals as nearly regular as possible. These soundings, together with the time at which they are taken and the horizontal angles for position, are recorded. The end of the line is also determined by angles; and the boat is then started on a new line. Thus the harbor or bay is crossed and recrossed by lines of soundings intersecting each other in numerous places; and these soundings, reduced to low-water level and laid down upon the chart, show the depth at low water not only in the channel but on the various shoals.

2. *Deep-Sea Soundings.* In this kind of hydrography the position of the vessel is determined from time to time by careful and numerous observations of the sun and stars, and by dead reckoning. The line used has recently been successfully replaced by a wire, and the lead or shot at the end of it is so arranged as to be detached on striking the bottom. An instrument called an indicator is attached to the sounding line, which, by means of revolving disks put in motion by a screw-propeller wheel, registers the depths to which it descends; when relieved of the weight of the lead, it is thrown out of gear and drawn up. The line is drawn in by a reel worked by a small steam engine; and by means of all these appliances soundings are taken at great depths with a rapidity and accuracy utterly unknown until of late years. Specimens of the bottom are obtained by means of specimen cups attached to the sounding line, or by the dredge. The best indicators now in use are those of Trowbridge and Brooke, the latter gentleman's having given thus far the best results.

3. *Hydrographic Surveys.* The process in a detailed survey is similar to that in a reconnaissance, but more elaborate. The hydrographer is furnished with the positions of numerous points on shore and with a map of the shores of the harbor in detail, on a scale to suit his own work. Upon this map are platted the points furnished him from the geodetic survey; and upon it he also constructs his lines of soundings. Usually two, and sometimes three officers are employed in each boat in running the lines, the advantage of this arrangement being that the two angles necessary to determine the position of the boat can be taken at the same moment by two observers without stopping the boat. Sometimes, especially where the work lies at a distance from the shore, two observers are placed on prominent points on shore, each with a theodolite. At stated intervals the surveying boat or vessel hoists a ball or flag, when both observers direct their instruments to her, and upon the instant of its being lowered measure the angle between the boat and some fixed point. The intersection of their two lines of sight when platted upon the chart gives the position of the boat. The lines of soundings are run more closely than in reconnaissance, and as far as possible are

made to cross each other at right angles. Tidal observations are made to tenths of a foot; and the box gauge, and at certain central points the self-registering gauge, are used. (See COAST SURVEY, vol. iv., p. 762.) The surveying parties, from the chief to the leadman, are specially trained for the work, and the resulting accuracy of such a survey is correspondingly great.—Physical hydrography investigates the laws of the formation of shoals, the effect upon harbors and channels of the tidal currents, of the extension of wharves, and of the dumping of earth and ballast; and endeavors to provide remedies for the changes which injure a harbor, and to suggest means for improving the channels. This branch of the science has of late years attained to great importance both in Europe and the United States, and the researches of those who have devoted themselves to its study have resulted in incalculable benefits to commerce. (See COAST SURVEY, vol. iv., p. 761.) In regard to currents, and other hydrographic details, see ATLANTIC OCEAN, and DREDGING (DEEP-SEA).

HYDROIDS, the lowest order of aculephs or jelly fishes, including, according to Agassiz, two distinct forms, one resembling polyps, the other like the jelly fishes, there being every possible gradation between the two. It is in this order that the phenomena of alternate generation have been specially studied by Sars and others. (See JELLY FISH.) There are many plant-like forms which give a mossy covering to seaweeds and stones, producing buds, developing in some cases into free medusæ, and in others remaining attached to the parent stalk, both discharging ova which swim off by ciliary processes to establish new fixed hydroid communities. In the tubularians the hydroid is pedunculated, and the bell-shaped medusæ are either free as in *coryne* or persistent as in *tubularia*. In the sertularians the hydroid is always pedunculated and attached, protected by a horny sheath, forming a cup around the head, with free medusæ as in *campanularia*, or free generative buds as in *sertularia*; their medusæ are flatter than in tubularians. The *siphonophora*, like the Portuguese man-of-war, are also hydroid communities.—The common green hydra of fresh water (*hydra viridis*) is easily seen by the naked eye; the body is a cylindrical tube, with thread cells, and a green coloring matter believed to be the same as the chlorophyl of plants; at the base is a disk-like sucker for its attachment to foreign bodies; it is usually suspended, head downward, from some aquatic plant, changing its position at will. The mouth is at the opposite end, surrounded by 5 to 15 very contractile tentacles, armed with lasso cells, hollow, and communicating with the general and stomachal cavity of the body; by these they obtain their food, which consists of minute aquatic animals. There are no internal organs of any kind, and they are therefore very little higher than the protozoa. They resist without destruc-

tion a very great degree of mutilation, each fragment into which they may be divided being capable, according to Trembley, of becoming a complete individual. Reproduction is either non-sexual, by gemmation in summer, or sexual, by ova and sperm cells in autumn;

Hydra.

the buds develop a mouth and tentacles at the free end, and are soon detached, each in its turn producing similar buds; both ova and sperm cells are produced in the same individual, coming in contact in the water; the embryo is at first ciliated and free swimming, afterward becoming fixed, losing the cilia, and developing a mouth and tentacles.

HYDROMECHANICS, that branch of natural philosophy which treats of the mechanics of liquids, or of their laws of equilibrium and of motion. It includes the consideration of those molecular properties of liquids which affect their mechanical applications, such as fluidity and slight compressibility. The science which is here termed hydromechanics has been sometimes treated under the title of hydrodynamics, this being made to include hydrostatics and hydraulics, which is the nomenclature adopted by Sir David Brewster; while others treat of hydrodynamics and hydrostatics as two independent subjects, hydraulics being embraced by hydrodynamics; but the title hydromechanics which was adopted in the first edition of this Cyclopædia seems to be the most comprehensive and exact, and will be retained.—Hydromechanics is comparatively a modern science, having received its greatest development in the 16th, 17th, and 18th centuries. The ancient mathematicians and hydraulic engineers, who constructed the aqueducts of Egypt and Assyria, must have been acquainted with many of the more obvious principles of hydraulics and hydrostatics; and at the time of the construction of the Roman aqueducts hydromechanics may be considered as having become entitled to be called a science; but the more purely mathematical principles by which its laws can be well understood were not discovered till centuries after.

Some of the general principles which lie at the foundation of the science, and are susceptible of analytical and experimental demonstration, were first given by Archimedes in the latter part of the 3d century B. C.; and it is to him that we owe the demonstration of the fundamental principle of the equilibrium of liquids, that each particle in a liquid at rest receives equal pressure in every direction, and also that a solid immersed in a liquid loses an amount of weight equal to that of the water displaced, from which he deduced the method of obtaining the specific gravity of bodies. We also owe to him the method of raising water by means of the screw known by his name. Other advances in the construction of hydraulic machinery were made about the same time in the Greek school at Alexandria by Ctesibius and Hero, who invented the syphon and forcing pump, and also the fountain known as Hero's; but their limited knowledge of pneumatics, and the imperfection in the machinery of those times, prevented them from bringing the force pump to anything like its present degree of efficiency. The first attempt at a scientific investigation of the motions of liquids was made by the consul Frontinus, who was inspector of the public fountains at Rome under the reigns of Nerva and Trajan, and whose book *De Aquæductibus Urbis Romæ Commentarius*, describing the nine great aqueducts of Rome, to which he afterward added five, contains all the knowledge of hydromechanics possessed by the ancients. From the statement of Pliny that water will rise to a level with its source, and that it should be elevated in leaden pipes, it appears that this metal was used by the ancient Romans for small conduits. Frontinus was the last of the ancients who paid much attention to the subject, the next investigator of importance being Stevinus, born about 1550, who was engineer of dikes for the government of Holland. He published a work in Dutch in 1586 on the "Principles of Statics and Hydrostatics," in which he restates the principle of Archimedes, and deduces from it the "hydrostatic paradox," that the pressure of a liquid on the bottom of a vessel may be much greater than its weight. By a method approaching the infinitesimal calculus, he found the pressure on the oblique bottom of a vessel; and Whewell remarks that his treatment of the subject embraces most of the elementary science of hydrostatics of the present day. Galileo, in his "Discourse on Floating Bodies" (1612), shows a clear knowledge of the fundamental laws of the science; but it is to his discovery of the uniform acceleration in falling bodies that we owe one of the chief foundations of hydromechanics. This law was afterward more fully applied by Torricelli in his celebrated theorem that the velocities of liquid jets are proportional to the square roots of the depths at which they issue below the surface, which he published at the end of his treatise *De Motu Gravium naturaliter accel-*

rato (1643). Pascal's work, written ten years later and published after his death, *Sur l'équilibre des liqueurs*, in which he treats the subject in a more systematic manner than any previous writer, contains complete and elegant demonstrations of most of the principles of hydrostatics, but does not treat of the motions of liquids. The next great student of hydro-mechanics was Sir Isaac Newton, who investigated the subject of friction and viscosity in diminishing the velocity of flowing water, and also of the velocity of jets; but upon the latter point he fell into an error by supposing that the velocity with which water issues from an orifice is equal to that which a body would attain by falling through half the vertical distance between the surface of the liquid and the orifice. His subsequent discovery of the *vena contracta* modified his conclusions, but his theory of efflux is open to objections. He, however, investigated the subject of waves, one of the most difficult in the science of hydrodynamics, in a manner worthy of his genius. In 1738 Daniel Bernoulli published *Hydrodynamica, seu de Viribus et Motibus Fluidorum Commentaria*, in which he founds his theory of the velocity of the motion of fluids through orifices upon the supposition that the surface of a fluid which is discharging itself by an orifice preserves a level, and that if the liquid is divided into an infinite number of horizontal strata, all the points in these strata will descend with velocities inversely proportioned to their breadth, or to the horizontal section of the reservoir. To determine the motion of each stratum, he employed the principle of "conservation of living forces;" and from the elegance of his solutions his work is pronounced by the abbé Bossut one of the finest productions of mathematical genius. But the uncertainty of the principle which he employed rendered the results of his work of less value than their mathematical excellence. The science afterward received the attention of D'Alembert and of Euler, who enriched it by the application of special mathematical methods of great acuteness and originality. The abbé Bossut also experimentally investigated the discharge of liquids by orifices, and added much to the stock of knowledge on the subject. To the experiments of Venturi, Eytelwein, and others, the science is indebted for many facts in regard to the flow of water from conically diverging tubes. The flow of water over barrages has been from time to time investigated experimentally by the chevalier Dubuat, D'Aubuisson, Castel, and M. Prony, and also by Smeaton, Brindley, Robinson, Evans, Blackwell, and others.—Before considering the separate branches of the subject, we will notice two important physical properties of liquids, as upon them the action of hydrostatic and hydraulic forces depends. The first important property of a liquid is the perfect mobility of its particles over each other, and one which results from their slight cohe-

sion. That there is a certain degree of cohesion is shown by the fact that liquids will form drops. There is no active repulsion between the particles until they have been heated to a certain degree; or the repulsion, if there is any, on the hypothesis that both forces are always in action, is less than the cohesion. A certain degree of cold, varying with the liquid, will cause an increase of the cohesive force, so that the liquid will become viscous and then solid; and it is found that the fluidity of a liquid is promoted by heat, and that water when cold will not flow through pipes as rapidly as when warm. The second important physical property of liquids is their great resistance to compression, so that for a long time it was doubted whether water was compressible. The experiment of Bacon, who hammered a leaden vessel filled with water till it was forced through the pores of the metal, was cited as a proof of the incompressibility of water; but a remark of Bacon's to the effect that he estimated the diminished space into which the water was driven, indicates that he drew a different conclusion. The experiment of the Florentine academicians in forcing water in a similar manner through the pores of a silver vessel was for some time regarded as indisputably establishing the incompressibility of water; but the apparatus devised by Oersted proves in a conclusive man-

FIG. 1.—Oersted's Apparatus.

ner that water and all other liquids are slightly compressible. Canton had previously shown that liquids were compressible, but the degree could not be ascertained with any accuracy in consequence of the difficulty of determining the amount of expansion which had been produced in the containing vessel. This was obviated by Oersted in placing it within another, so that it would receive equal pressure upon equal surfaces without and within, and thus preserve a uniform capacity. His apparatus is shown in fig. 1. The liquid to be subjected to pressure is placed in the inner glass vessel *a*, from the top of which a capillary tube turns downward, its open extremity dipping beneath the surface of a layer of mercury contained in the bottom of the outer vessel. Another tube, *b*, graduated and used as a manometer, also open at the lower end and dipping in the mercury, is placed along with the vessel *a* in a strong glass cylinder, which is provided at the

top with a smaller metallic cylinder which admits the compressing screw *c*, and also a funnel, *d*, for introducing the liquid. The vessel *a* with its capillary stem, having been filled with the liquid, is placed in position, together with the manometer; the outer cylinder is filled with water, the stopcock of the funnel closed, and pressure produced by turning the screw with a lever. Mercury will be seen to rise in the capillary tube connected with the vessel *a*, showing that its contents are diminished in volume. The air contained within the manometer, being reduced in bulk in proportion to the force exerted, according to the law of Boyle and Mariotte, will therefore be a measure of that force. Oersted at first assumed that the external and internal pressure on the vessel was precisely the same; but the external pressure is slightly the greater, because the external surface is greater than the internal, so that the capacity of the vessel is diminished, instead of being increased as in all preceding experiments. Colladon and Sturm with the use of this apparatus made very exact experiments, in which they calculated the change of capacity of the vessel *a*, and estimated that an additional atmospheric pressure would reduce the volume of water .00005, mercury .000005, and sulphuric ether .000133. For water and mercury it was found that within certain limits the decrease in volume is proportional to the pressure. I. HYDROSTATICS. In consequence of the mobility of the particles of a liquid over each other, they yield to the force of gravity, and consequently when at rest present a level surface; and for the same reason each particle, and therefore each portion of the liquid, must exert and receive equal pressures in all directions. If this were not true, the particles of a liquid could not come to a state of rest. From this principle it follows that equal surfaces of the sides of a vessel containing a liquid receive equal pressures at equal depths below the surface; and also that if a close vessel is filled with a liquid which we will suppose to have no weight, and if an aperture of the size of one square inch be made in one side of it and fitted with a piston upon which there is exerted a pressure of 10 lbs., there will also be exerted the same pressure of 10 lbs. upon every square inch of the internal surface of the vessel. Consequently, if another aperture of 100 square inches area is made in the side of the vessel, and a cylinder of the same size is fitted to it, a piston fitted to this will receive a pressure of 1,000 lbs. Upon this principle (which has been ascribed to Pascal, but which, as we have seen, was before his time explained by Stevinus) the hydraulic press is constructed, as represented in fig. 2. A suction and force pump, *a*, supplied from the cistern *B*, forces water through the tube *C* into the strong cylinder *V*, which communicates pressure to the piston *A*. The power gained is the proportion which the cross section of the large piston or plunger bears to the small one. It will be ob-

served that the pistons do not fit the cylinders in the usual manner, but only fit tightly at the collar. This mode of construction greatly increases the efficiency of the machine, which, though described by Stevinus and by Pascal, remained practically useless in consequence of

Fig. 2.—Hydraulic Press.

the escape of water between the cylinder and the piston, until Bramah invented the cupped leather collar, which makes the apparatus equally water-tight under all pressures. This engine is a good illustration of the law in mechanics that "what is lost in velocity is gained in power." If the cross section of the large piston is equal to 100 square inches, and that of the small piston to 1 square inch, the latter must be moved through a space of 100 inches to cause the large piston to move through one inch, but it will move with 100 times as much power as the small one. The hydrostatic bellows, shown in fig. 3, acts upon the same principle as the hydrostatic press, the cover of the bellows, upon which the weight is placed, performing the office of the large piston, while the column of water in the tall vertical pipe acts the part of the small piston of the press. The hydrostatic bellows also illustrates the principle of the hydrostatic paradox, for the vertical pipe and the bellows are virtually one vessel, whose base is the bottom of the bellows. Now the pressure exerted by the liquid in the pipe upon the upper plate of the bellows is received by the lower plate, which also has an additional pressure equal to its distance below the upper plate; and if the water in the pipe is ten times as high as that in the bellows, it follows that the pressure on the bottom plate will be ten times as great as that which would be produced by the liquid contained within the bellows itself, for that only is equal to its own weight. If a barrel of water therefore have a tall tube inserted in one head

Fig. 3. Hydrostatic Bellows.

and standing vertically, a pressure may be produced on its bottom several thousand times that due to the weight of the water alone. In accordance with this law of hydrostatic pressure, a liquid will rise to the same height in different branches of the same vessel, whether these branches be great or small.

Fig. 4.

Thus, water contained in the U-shaped vessel, fig. 4, will rise to the same height in both branches, which is an illustration of the principle that the pressure of a column of liquid is in proportion to its height and not to its quantity.

This principle, however, if it is entitled to such a name, proceeds directly from the principle of Archimedes that each particle in a liquid at the same depth receives an equal pressure in all directions. If however one leg of a U-shaped tube contain mercury and the other water, the column of water will stand $13\frac{1}{2}$ times as high as that of mercury. It follows from the fact that a liquid presses equally upon equal areas of a containing vessel at the same depth, that if a hole is made in one side of a vessel, less pressure will be exerted in the direction of that side; and therefore if the vessel is floated on water, as in fig. 5, it will be propelled in the direction of the arrow.

Fig. 5.

Fig. 6.
Barker's Mill.

air, which proves that the propelling force is the preponderance of pressure in one direction. The two following are important laws of hydrostatics: 1. The hydrostatic pressure against equal areas of the lateral surfaces of cylindrical or prismoid vessels, commencing from the surface of the liquid, varies as the odd num-

bers 1, 3, 5, 7, &c. 2. The hydrostatic pressure against the entire lateral surfaces of cylindrical or prismoidal vessels is proportional to the square of the depth. The first law is demonstrated as follows: Hydrostatic pressure in any direction at any point in a liquid is in proportion to the depth, a result due to the action of gravity; therefore the mean pressure against any rectangular lateral area will be on a horizontal line midway between the upper and lower sides of such area. The depth of this line, proceeding from the surface of the liquid downward, varies as the odd numbers 1, 3, 5, 7, &c., as will be seen by an inspection of the adjoining diagram, fig. 7. The figures placed upon the dotted lines in the centre of the areas indicate the pressures upon those

areas. The figures on the right side of the diagram indicate the pressures at points of equal vertical distances, while those upon the left indicate the total lateral pressures, which it will be observed are the squares of the number of areas included; by which is demonstrated the second law, that the total lateral pressure against rectangular areas is in proportion to the square of the depth. The weight of a cubic foot of water is 62.5 lbs.; therefore the lateral pressure against a surface

Fig. 7.

of a square foot, whose upper side is in the surface of the liquid, is 31.25 lbs. From this it is easy to ascertain the pressure against a square foot, or any area, at any depth below the surface. Simply multiplying the number of feet below the surface by 2 and subtracting 1, multiplying the remainder by 31.25 and this product by the number of horizontal feet, will give the pressure of a stratum of water a foot deep, at any depth below the surface and of any length. To ascertain the entire pressure against the sides of a vertical cylindrical or prismoidal vessel, square the depth of the liquid in feet or inches, and multiply this by the lateral pressure against an upper vertical square foot or inch, as the case may be, remembering that the weight of a cubic inch of water is .5792 of an ounce, and therefore that the pressure against an upper lateral side is .2896 of an ounce. The total pressure exerted against the sides of a cylindrical pipe 60 ft. high and 2 in. in diameter is found as follows: $60^2 \times 31.25 = 112,500$. The diameter of the inner surface is 2 in., the circumference of the inner surface is 2×3.141592 (the constant ratio) = 6.283184 in., or $\frac{6.283184}{12}$ of a foot. Therefore, $112,500 \times \frac{6.283184}{12} = 58,904.92$ lbs. or 29.95 tons. The lateral pressure on the lower foot would be $(60 \times 2) - 1 = 119 \times 31.25 \times \frac{6.283184}{12} = 1,959.64$

lbs., or a little less than one ton. In the construction of walls for resisting only the hydrostatic pressure of water, as that pressure is in proportion to the depth, the strength of the wall should be in the same proportion. If strength were not given to the lower layers by superincumbent pressure, the inclination of the slope should be 45°; but in consequence of this pressure it may be less, varying with the materials and their manner of being put together. In the construction of dams or barrages the varying circumstances of cases allow of the display of a good deal of engineering skill. A barrage suitable for restraining a body of water which is never strongly moved in a lateral direction against it, as at the outlet of a canal or a reservoir fed by an insignificant stream, would not be adapted to a mountain torrent, where the surface of the reservoir can scarcely ever be large enough to prevent, by the inertia offered by a large mass of water, the walls from being subjected to a strong lateral force from the action of the current. Under such circumstances it is usual to give a curved surface to the facings, in a vertical as well as in a horizontal direction; the curves in both directions being calculated from the following elements: 1, the ascertained hydrostatic pressure; 2, the nature of the materials, such as the weight of stone and tenacity of the hydraulic cement used; and 3, an estimate of the maximum force of flowing water which may at any time be brought against the structure during a freshet. This force, it will readily be seen, will have a different direction and a different point of application in different cases, depending upon the depth and extent of the reservoir. The top of the dam is therefore given a greater horizontal section than would be called for if hydrostatic pressure alone had to be opposed. The hydrostatic pressure at any point against the surface of a containing vessel is the resultant of all the forces collected at that point, and is therefore at right angles to that surface. In a cylindrical or spherical vessel these resultants are in the

Fig. 8.—Centre of Pressure.

The simplest case and its general application only will be considered here, viz., that of the centre of pressure against a side of a rectangular vessel. Let any base in the triangle A B C, fig. 8, represent the pressure at B; then will D E represent the pressure at E, and all lines paral-

lel to it will represent the pressures at corresponding heights. The finding of the centre of pressure now consists in finding the centre of gravity of the triangle A B C, which will be at H, the intersection of the bisecting lines E C and D B, and at one third the height of the side A B; consequently the centre of hydrostatic pressure against the rectangular side A B is at G, one third the distance from the bottom to the surface of the liquid. The average intensity of pressure against A B being at E, one half the depth of A B, therefore the total pressure on the rectangular side A B will be the same as if it formed the bottom of the vessel and was pressed upon by a column of water of half the depth of A B. In general, the total pressure on any surface, plain or curved, is equal to the weight of a liquid column whose base is equal to that surface, and whose height is the distance of the centre of gravity of the surface from the surface of the liquid.—*Principle of Archimedes.* A solid immersed in liquid loses an amount of weight equal to that of the liquid it displaces. This is called the principle of Archimedes, and is demonstrated as follows: Let a b, fig. 9, be a solid immersed in a liquid. The vertical section c d will be pressed downward by a force equal to the weight of the column of water e c, and it will be pressed upward by a force equal to that exerted by a column of water equal to e d; therefore the upward or buoyant pressure exceeds the downward pressure by the weight of a column of water equal to the section c d. Now, this section also exerts a downward pressure; and if the body is denser than the liquid, the downward pressure will be greater than the excess of the upward pressure of the liquid, and the body will sink if not supported; but if the body is less dense than the liquid, the downward pressure of the column e d will be less than the upward pressure exerted against it, and the body will float. This principle may be experimentally demonstrated by the hydrostatic balance, fig. 10. From a balance, b, is suspended a cylindrical vessel, a, from which again is suspended a solid cylindrical vessel, c, which is of such bulk and dimensions

Fig. 9.—Principle of Archimedes.

Fig. 10.—Experimental Verification of the Principle of Archimedes.

as just to fill the vessel a when introduced. The whole system is first balanced by weights at the other end of the beam, and then c is immersed in water. The equilibrium will be destroyed, and that the body c loses a portion

of its weight equal to that of an equal bulk of water is proved by filling the vessel *a* with water, when the equilibrium of the balance will be restored. It is by means of a similar apparatus that the specific gravities of solids is ascertained (see GRAVITY, SPECIFIC); and upon the principles already laid down hydrometers, or instruments for ascertaining the specific gravity of liquids, are constructed. (See HYDROMETER.) It is thus also shown why it is easier to raise weights in water than in air, and why fat persons sustain themselves in water more easily than those who are lean.

FIG. 11. Cartesian Diver.

The air bladder in fishes is for the purpose of enabling them to rise or descend in the element in which they live. This rise and fall by varying the specific gravity is beautifully illustrated by means of the little toy called the bottle imp or Cartesian diver, fig. 11. A bottle is nearly filled with water, and a hollow image of glass or metal and lighter than water, or several little balloons of glass, each of them having an opening below through which water may flow in and out, are introduced into

the bottle or jar, which then has its mouth covered with a sheet of caoutchouc, or some elastic membrane. Pressure upon this will compress the air beneath it, and to the same degree the air which is contained in the upper part of the image or the balloons, so that their specific gravity is increased enough to make them sink. Removal of pressure will allow the confined air to resume its former bulk, by which the specific gravity will again become less than that of the water, and they will again ascend. If their surfaces have oblique or spiral directions, and the air is properly distributed, the images may be made to perform various curious evolutions.—*Stability of Floating Bodies.* There are certain points to be observed in determining the stability of floating bodies; these are: 1, the centre of gravity of the floating body; 2, the centre of buoyancy; and 3, the metacentre. When a body floats upon water it is acted on by two forces: 1, its own weight, acting vertically downward through its centre of gravity; 2, the resultant force produced by the upward pressure of the liquid, which acts through the centre of gravity of the fluid that is displaced, which point is called the centre of buoyancy of the body. It follows, therefore, that these two points, the centre of gravity and the centre of buoyancy, must be in the same vertical line for the body to be in a state of equilibrium; for otherwise the two forces, one acting downward and the other upward, would form a couple which would cause the body to turn. When these two centres are in the same vertical line, but the centre of gravity is above, the body, except in some cases to be noted presently, is

in a state of unstable equilibrium; but when the centre of gravity is beneath, the body is in a state of stable equilibrium. If a body is floating in a liquid and is entirely immersed, it will not come to a state of stable equilibrium until the centre of gravity is vertically below

FIG. 12.

the centre of buoyancy. This is shown in fig. 12, in the case of bodies which are less dense at one end than at the other, where B and B' are the centres of buoyancy and G and G' those of gravity.

But in many cases, when a body is only partially immersed, the centre of gravity may be above that of buoyancy, and yet the action of turning cannot take place, so that a condition of stable equilibrium will be attained under these circumstances. If a flat body, such as a light wooden plank, is placed in water, it will float, and a portion will be above the surface, as

FIG. 13.

FIG. 14.

shown in fig. 13; and therefore, if the centre of gravity is not below the centre of volume, it will be above the centre of buoyancy, and yet the body will be in a state of stable equilibrium. For if it be tipped as represented in fig. 14, the centre of buoyancy will be brought to the position B', on the depressed side of the vertical passing through the centre of gravity, and this will cause the body to return to its former position. But if the body has such a shape that when it is displaced the centre of buoyancy is brought to that side of the vertical passing through the centre of gravity, which is elevated as represented in fig. 15, then the body will turn over. When the body is in the new position, a vertical drawn through the changed position of the centre of buoyancy will intersect the line which in the first position passed vertically through the centre of gravity, and this point of intersection is called the metacentre, represented at M in figs. 15 and 16. When the metacentre is above the centre of gravity, as in fig. 16, the body will tend, by the action of the centre of buoyancy, to return to its former position; but when it is below, as in fig. 15, the action of the centre of buoyancy, being upward on the elevated side, will tend to turn the body over. Its proper place therefore, as its name would indicate, is above the centre of gravity, but it cannot be a fixed point. In all well built ships, however, its position is pretty nearly constant for all inclinations. For example, in fig. 16, as long as increase of inclination of the vessel carried

the centre of buoyancy B to the left, the point M might remain at nearly the same distance from G, because it would also move to the left. But if the inclination of the vessel in the same direction carried the centre of buoyancy

FIG. 15.

FIG. 16.

to the right, the height of the metacentre M would diminish until it would be in G, when the equilibrium would be indifferent, and at last below G, when the ship would turn over. It is desirable to have the metacentre as far as possible above the centre of gravity, and this condition is secured by bringing the centre of gravity to the lowest practicable point, by loading the ship with the heaviest part of the cargo nearest to the keel, or by employing ballast. II. HYDRODYNAMICS, although it embraces many of the principles of hydrostatics, treats more particularly of the laws of liquids in motion. One of the most important principles of hydrodynamics is that which determines the velocity of jets which issue from orifices at various depths in the sides of vessels containing liquids, and depends upon the laws of hydrostatic pressure. If an orifice is made in the side of a vessel containing a liquid, the liquid will issue from it with a velocity equal to that which a heavy body would acquire in falling through the vertical distance between the surface of the liquid and the orifice. If the jet is directed upward, it will ascend, theoretically, to a level with the surface of the liquid; but practically it will fall short of this in consequence of friction at the orifice, and of the resistance offered by the air. At first sight it would appear that the velocity of efflux would be proportional to the pressure, but an analysis of the case, aside from the test of experiment, will show that this cannot be, for in no instance can the jet be projected higher than the surface of the liquid. If, in general terms, the velocity of a jet were in proportion to the pressure at the point of issue, a column of mercury would throw a jet with $13\frac{1}{2}$ times the velocity that an equal column of water would; but it must be perceived that a column of mercury can only propel a jet as high (theoretically) as the surface, and therefore to the same height as an equal column of water can. Now, there can be no doubt that the pressure of mercury at the same depth is $13\frac{1}{2}$ times that of water; but mercury, being also $13\frac{1}{2}$ times as heavy as water, has $13\frac{1}{2}$ times as much inertia, and therefore requires so many times as much force to give it the same initial velocity. The velocity with which a liquid escapes from an orifice varies as the

square root of the depth below the surface; so that when the points of escape are 1, 4, 9, and 16 ft. in depth, the initial velocities will be as 1, 2, 3, and 4. This is the celebrated theorem of Torricelli, which he deduced from the laws of falling bodies. As the velocity of a falling body is in proportion to the time of its fall, it will be in proportion to the square root of the height fallen through, and is represented by the formula $V = \sqrt{2gh}$, in which g is the accelerating force of gravity ($= 32.2$), and h the height. (See MECHANICS.) A jet issuing from the side of a vessel describes, theoretically, a parabola, precisely as in the case of a solid projectile; for the impelling force and the force of gravity act upon the jet in the same manner, and the resultant force gives it the same direction. The range, or distance to which the jet is projected, is greatest when the angle of elevation is 45° , and is the same for elevations which are equally above or below 45° , as 60° and 30° . The resistance of the air however alters the results, and the statement is only true when the jet is projected into a vacuum. If a vessel filled with water have orifices made in its side at equal distances in a vertical line from the top to the bottom, a stream issuing from an orifice midway between the surface and the bottom will be projected further than any of the streams issuing from the orifices above or below. This may be demonstrated by the adjoining diagram, fig. 17. Let a semicircle A F E be described on the side of a vessel of water, its diameter being equal to the height of the liquid. The range of a jet issuing from either of the orifices B, C, or D will be equal to twice the length of the ordinates B F, C I, or D K respectively; and therefore jets issuing from B and D will meet at a point H on a level with the bottom, and twice the length of the ordinates B F and D K. Now, as the ordinate C I is the great-

FIG. 17.

est, the range of the jet issuing from C will be greater than that of any other jet. The amount of water escaping in one second from an orifice would, theoretically, be equal to a cylinder having a diameter equal to that of the orifice, and a length equal to the distance

through which a body will move with a uniform velocity after it has fallen through a height equal to the vertical distance between the surface of the liquid and the orifice. If this distance is 16.1 ft., the velocity acquired will be 32.2 ft. per second, and therefore the theoretical quantity discharged from an orifice 4 in. in diameter, whose centre is 16.1 ft. below the surface, would be equal to a cylinder 4 in. in diameter and 32.2 ft. long, and containing 4,828.5 cubic inches, or about 21.83 gallons. The actual discharge from a thin orifice not furnished with an ajutage is however

Fig. 18.—Vena Contracta.

much less, being only about two thirds of the theoretical amount. The loss is owing partly to friction, but mainly to the interference of converging currents moving within the vessel toward the orifice. This interference may be shown by employing a glass vessel having a perforation in its bottom, as represented in fig. 18. If particles of some opaque substance having nearly the same specific gravity as water, so that they will remain suspended in it for a space of time, be mingled with the water, they will be seen to move in the direction indicated by the lines in the figure, which are nearly direct. If the jet is carefully observed, it will be seen that it is not cylindrical, and that for a distance from the orifice of about half its diameter it resembles a truncated cone with the base at the orifice. This contraction of the stream is called the *vena contracta*, and its smallest diameter is stated to be from 0.6 to 0.8 of that of the orifice. When the stream has a direction downward nearly vertical, it continues to diminish beyond the vena contracta, in consequence of the increased velocity caused by the force of gravity, the size being in the inverse proportion to the velocity. The increased velocity at the vena contracta is due to the pressure which forces the particles of water into a narrower channel. As the jet continues to fall, it forms a series of ventral and nodal segments, as shown in fig. 19. The ventral segments are composed of drops elongated horizontally, as shown at *a a*, while the nodal segments are elongated vertically, as seen at *b b*; and as the segments have fixed positions, it follows that the drops in falling are alternately elongated vertically and horizontally. If the orifice is in the side of the

Fig. 19.

vessel and discharges horizontally, the size of the stream does not diminish in the same manner as when falling vertically, and it is sooner broken. If a cylindrical tube or ajutage whose length is from two to three times its diameter is fitted to the orifice, the rate of efflux may be increased to 80 per cent. of the theoretical amount. The velocity will be somewhat diminished, but the vena contracta will be larger in proportion. If the inner end of the ajutage has a conical shape with the base toward the interior, the efflux may be further increased to 95 per cent.; and it has been found that if the outer end of the tube is also enlarged, the efflux may be still further increased to very nearly the theoretical amount, say 98 per cent. When a cylindrical ajutage is used, there will be a partial vacuum formed between the sides of the tube and the contracted vein, as shown in fig. 20. If a pipe ascending from a reservoir of water is let into this part of the ajutage, the water will rise in the pipe; and if the height is not too great, the vessel may be emptied.—The resistance offered by conduits is a subject of great importance in practical hydro-

Fig. 20.

mechanics, upon which extended experiments have been made. When the length of the ajutage bears more than a certain proportion to its diameter, the efflux is reduced to about the same amount as when the stream issues through a thin orifice, that is, about 62 per cent. of the theoretical amount. With a pipe of 1 1/4 in. in diameter and 30 ft. long, the efflux will be only about half that from a thin orifice, or 31 per cent. of the theoretical amount. This reduction is caused by friction between the liquid and the tube, as well as between its particles, and is greater with cold than with warm liquids. This resistance to motion, or approach to rigidity, which is conferred by cold, is called viscosity, and is a principle which has to be taken into account in nearly all very careful hydraulic calculations.—*Resistance of Liquids to the Motion of Solid Bodies.* This will depend upon the form and size of the body. The following are two important laws: 1. With the same velocity, the resistance is proportional to the extent of surface applied by the solid to the liquid in the direction of motion. 2. With the same extent of surface, the resistance is proportional to the square of the velocity. These laws may be demonstrated experimentally, but their truth will also be apparent from the following considerations. In regard to the first law, it will be easily understood that with the same velocity the amount of water displaced will be the measure of resistance, and that a surface of two square feet will displace twice

as much as one of one square foot. The second law is not so evident, but will be made clear by considering that with a given surface, when the velocity is doubled, twice the quantity of liquid will move through twice the space in the same time, and will therefore, according to the principles of mechanics, have a fourfold momentum. The resistance, therefore, offered to a plane surface moving at right angles against a liquid, is measured by the area of the surface multiplied into the square of the velocity. It has been found that a square foot surface, moved through water with a velocity of 32 ft. per second, meets with a resistance equal to a weight of 1,000 lbs. When the motion of a body in a liquid is very slow, say less than 4 in. per second, depending on the size of the body, the larger body requiring to move more slowly, the above laws are not rigidly followed, but the resistance is divided into two components, one of which is proportional to the simple velocity, and the other to the square of the velocity. The most accurate results in experimenting with slow motions were obtained by Coulomb, who used his torsion balance. One of the most interesting problems in mathematics has been to determine the form of a solid which will meet with the least resistance in moving through water. This form is called the "solid of least resistance," and is approached as near as practicable in the construction of ships.—*Theory of Waves in Liquids.* When a pebble is dropped into still water, a series of circular waves is formed upon its surface, which extend themselves from the centre in all directions. These waves consist of alternate elevations and depressions, which have the appearance of following one another in the direction of the radii of the circle. It is however only an appearance, as may be readily proved by throwing a cork upon the undulating surface, when it will be observed only to rise and fall, and the undulations will appear to glide beneath it. The wave then is an oscillation of the liquid upward and downward, and the force which causes it is gravity. The pebble when it strikes the water displaces a portion, which rises on every side to a certain height, and then, its momentum being lost, and being higher than any portion of liquid around it, it falls; but the momentum it has acquired carries it below the level, and an exterior ring is forced upward, which in descending also produces a successor; and thus a series of circular waves is formed of gradually diminished height but of increased diameter, until, at a very great distance in calm water, the force of the primary impulse is lost. When two waves proceeding from different centres meet one another in such a way that the elevations coincide, a united wave will be produced having a height equal to that of its two components, and a depression equal to that of the other two; but if the elevation of one corresponds to the depression of the other,

the resulting elevation and depression will be equal to the difference of elevation and depression respectively of the original waves. If they are equal, the result will be the obliteration of both. This phenomenon is called the interference of waves. It is susceptible of demonstration that the undulations of waves are performed in the same time as the oscillations of a pendulum whose length is equal to the distance between two eminences, or the technical breadth of the wave.—*Form of Surface of Rotating Liquid.* From the principle of the equilibrium of fluids, that the surface of the liquid at rest must be a level which is perpendicular to the direction of the force of gravity, it follows that when two or more forces act upon a liquid to change the position of its surface, the resultant of these forces will be perpendicular to the surface. Therefore, if a cylindrical or conical vessel, fig. 21, containing a liquid, is rotated on its axis AB , all the particles on the surface will be acted upon by two forces, that of gravity, in a vertical direction represented by AC or CE , and the centrifugal force, represented by CD or EF , which is horizontal, and varies in intensity with the distance of the particles from the axis or centre of motion. The surface of the liquid will therefore be depressed in the middle, and will be at every point perpendicular to the resultants AD , CF , &c., which will therefore be normals; and it may be demonstrated that the subnormals AC , CE , &c., are equal, and therefore that the surface of the liquid is a paraboloid.—*A Level Surface.* Let it be assumed that if the earth were entirely covered with water, and at rest, with no force acting upon the water except gravity, it would have the form of a perfect sphere. But it has been found to have the form of an oblate spheroid, the ratio of its polar to its equatorial diameter being about 299 to 300. Its oblate form is caused by its rotation on its axis. Let $abcd$, fig. 22, be the section of a liquid sphere, passing through its axis of rotation ab , and let f be any point on its surface. The revolution of the sphere on its axis will generate a centrifugal force in the direction of fe , parallel to the plane of the equator cd , and perpendicular to the axis ab . Now, if fh represent the force of gravity and fe the centrifugal force, fg will represent the resultant of these two forces, and the surface of the liquid, being free to move, must become perpendicular to this resultant at every point. The surface of a

FIG. 21.

FIG. 22.

revolving body, like the earth, if covered with a liquid, would have a form like that represented in section by the dotted line, and it may be demonstrated that this form is that of a spheroid formed by an ellipse revolving about its minor axis. Its surface, to which that of the earth approaches, is called a level surface.

HYDROMETER, or **Areometer**, an instrument for determining the specific gravity of liquids. It generally consists of some buoyant body, as hollow glass or copper, weighted at the bottom and supporting a graduated stem, or one having a definite mark. There are two kinds, those of constant and those of variable immersion. Those of constant immersion are made to sink in the tested liquid, whether

Fig. 1.—Nicholson's Hydrometer.

dense or light, to the same depth, by balancing with weights. Those of variable immersion have no movable weights, but rise or fall according to the density of the liquid. Nicholson's hydrometer, fig. 1, is of the first kind. As usually constructed, when this instrument is immersed in water it requires a weight of 1,000 grains to make it sink to a certain mark on the stem. According to the principle of Archimedes (see **HYDRO-MECHANICS**), the weight of the instrument, together with the 1,000 grains which it sustains, is equal to the weight of the volume of water displaced. If the instrument is placed in a liquid lighter or heavier than water, and the weight changed until it sinks to the same depth, the specific gravity of the liquid will be indicated by the formula

$$g = \frac{W + w}{W + 1000},$$

where W is the weight of the instrument, and w that of the weights placed upon the pan. If w is less than 1,000 grains it will show that the liquid is lighter, and if it is more than 1,000 grains it will show that it is heavier than water. This instrument may also be used to find the specific gravity of solids, or as a delicate balance. For these purposes it has a small cup or wire cage suspended at the bottom to hold the body, which may be either heavier or lighter than water. To find the specific gravity of a solid, let it be first weighed in air, by placing upon the pan a piece of the substance which weighs less than 1,000 grains. Suppose the substance to be sulphur, and that 440 grains are required to be added

to make the instrument sink to the mark on the stem, the weight of the sulphur is, evidently, $1,000 - 440 = 560$ grains. Now, what it loses if weighed in water will be the weight of an equal bulk of water, and this will be found by placing it in the cup or cage at the bottom, and adding sufficient weights to those in the pan at the top to bring the mark to the level of the water. If it requires the addition of 275.2 grains, that amount will represent the weight of a volume of water equal to the sulphur; consequently the specific gravity of the sulphur will be $\frac{560}{275.2} = 2.03$. If the body is lighter than water, it will of course require the addition of more than its weight to the pan, and for immersion it will require to be placed in the wire cage. Fahrenheit's hydrometer differs from Nicholson's in being constructed of glass, and having a constant weight of mercury in a bulb at the lower end. Its use is therefore restricted to the weighing of fluids.—Of hydrometers of variable immersion, Baumé's is the one most frequently used, and furnishes a good example of the class. Two instruments, of different forms, are represented in figs. 2 and 3. They are made of glass; their stems are hollow and lighter than the fluid in which they are immersed. Fig. 2 is called a salimeter, and is used for estimating the proportion of a salt or other substance in solution. It is graduated in the following manner: Being immersed in water at a temperature of 12° C., the point to which it sinks is marked 0° ; it is then placed in a solution containing 15 parts of common salt to 85 of water, the density of which is about 1.116, and the point to which it sinks is marked 15, and the interval divided into 15 equal parts; the graduation is then extended downward, generally terminating at 66° , which corresponds to the density of sulphuric acid. When the instrument is to be used for liquids lighter than water, the zero is not placed at the point to which it sinks in pure water, but at a point to which it sinks in a solution containing 10 parts of common salt to 90 of water. The point to which it sinks in pure water was marked by Baumé 10° , and the graduation was continued upward to the highest point to which the stem might be immersed in the lightest liquid. Fig. 3 represents the instrument for liquids lighter than water. The graduation of these hydrometers is arbitrary, and is an indication of the strength of the liquid only after trial.—Hare's hydrometer, a

Fig. 2. Salimeter. Fig. 3. Alcoholimeter. Baumé's Hydrometers.

very valuable instrument, but one which has not been much employed, acts upon the principle of the barometer, and yields directly results of definite comparison; it is represented in fig. 4. A \cap -shaped tube has its legs, of equal length, placed in shallow vessels, one containing the liquid to be tested, and the other a liquid taken as a standard, as water. A partial vacuum is then produced in the tube by exhausting the air by means of an air pump, the mouth, or otherwise, making use of the stop-cock to facilitate the operation. It is evident that the height of the liquid column will be in the exact inverse proportion to the specific gravity of the liquids.—Hydrometers have various names, according to the purpose for which they are used: as lactometers, for estimating the amount of cream in milk, or the quantity of sugar of milk in the whey; vinometers, for estimating the percentage of alcohol in wine or cider; and there are acidometers and saccharometers.

FIG. 4.—Hare's Hydrometer.

HYDROPATHY (Gr. *ὕδωρ*, water, and *πάθος*, affection or disease), a system of treatment of diseases mainly or exclusively by the use of water and of the known hygienic agencies. Hygienic management in some form, as a resort to exercise, or, in diseases induced by luxurious living, to abstemiousness, dates from the earliest conception of a healing art; and it has kept pace with the growth of physiological science, until within the present century the laws and claims of hygiene have become appreciated as never before. The physicians of very early times seem also to have employed water as a remedy in certain febrile, inflammatory, and surgical maladies; a usage recommended, among other early medical writers, by Hippocrates, Galen, and Avicenna. In the 18th century Sir John Floyer and Dr. Baynard, in England, resorted to bathing almost exclusively in chronic diseases; as did F. Hoffmann and Hahn on the continent. Dr. James Currie in 1797 published highly favorable reports of the effects of water, chiefly by affusion, in many diseases. But the distinctive "water cure," or hydrophaty, owes its origin to the fertility of invention of a Silesian peasant, Vincenz Priessnitz. Having at the age of 13 sprained his wrist, young Priessnitz intuitively applied it to the pump; and afterward, to continue the relief thus obtained, he bound upon it an *Umschlag*, or wet bandage. Rewetting this as it became dry, he reduced the inflammation, but excited a rash on the surface of the part. Soon after, having crushed his thumb, he again applied the bandage, and the pain once more subsided, but the rash reappeared. He inferred that the rash indicated an impure blood; and this conclusion was

strengthened by the result of experiments which he was induced to try upon injuries and ulcers in the case of some of his neighbors, since the rash in some instances appeared after the treatment, and in others did not. Thus he was led to frame for himself a humoral pathology of all diseases, and a doctrine of the elimination of morbid matters by "crisis." According to this view, the cure of disease is to be effected by favoring the activity of those organs through which the purification of the system is carried on, and, through a regulated and pure dietary and correct regimen, preventing further morbid accumulations. In his 19th year, being run over by a cart, Priessnitz had some ribs broken and received severe bruises; on learning that the physicians pronounced his case hopeless, he tore off their bandages, and recovered under the renewed application of the *Umschlag*, and replaced his ribs by inflating the lungs while pressing the abdomen against a window sill. This incident confirmed the idea and initiated the practice of the water cure. In the new practice, its author discovered in rapid succession the means of securing either cooling, heating, or soothing effects by compresses; then, the sponge bath, the wet-sheet packing, the sitz, foot, arm, and other partial baths, the douche, the stream bath, the dripping sheet, the plunge, the tepid shallow bath, dry-blanket packing, &c. The pail douche of Dr. E. Johnson is one of the very few additions since made to this list of measures. Unquestionably, Priessnitz's earlier treatment, especially after the opening in 1826 of the famous Gräfenberg cure, was too incessant and severe, and often borne only through the vital tenacity, whatever their maladies, of the class of invalids with whom he had to deal. Along with this was introduced a rigorous, but in some respects mistaken hygiene, including the very free use of a plain and peculiar diet, much walking in the open air, and the disuse of flannel undergarments and of soft beds. The water appliances have since been rendered more mild, and in the United States necessarily so. The number of instances, however, of decided restoration to health among the invalids who flocked from all parts of Europe and of the United States to the Gräfenberg cure, sufficiently explains the rapid spread of the new system. This was first distinctly brought to the notice of the English public about the year 1840, by a book put forth by a former patient of Priessnitz, Capt. Claridge, and entitled "Hydrophaty, or the Cold Water Cure." In Germany, under Francke, Weiss, Munde, and others, the enthusiastic treatise of the first of whom did much to spread the system, several new establishments had already sprung up. On March 17, 1842, the hydrophatic society was organized in London, for the purpose, among others, of circulating information in regard to Priessnitz, and the authenticity of the reported cures. Drs. Wilson, Johnson, and Gully were first to em-

brace the practice, the first two early lecturing before the new society, and all soon establishing institutions of their own. The writings of Drs. Gully and Johnson contributed much to spread the system in England, and at a later day they were ably seconded by Bulwer's "Confessions of a Water Patient," detailing incidents of his restoration to health at the Malvern establishment. The earliest popular information concerning water treatment in the United States was through a letter published about 1843, from H. C. Wright, himself at the time a patient under Priessnitz; and this was soon followed by the earnest statements and appeals, through a like channel, of J. H. Gray of Boston and A. J. Colvin of Albany. Drs. Schieferdecker, Wesselhoeft, and Shew seem to have been the first to enter upon the new practice in the United States; while the first establishment appears to have been that opened in 1844 at No. 63 Barclay street, New York. Of this, David Cambell, also the originator of the "Water-Cure Journal," was proprietor, and Joel Shew physician. In May, 1845, an establishment was opened at New Lebanon Springs, N. Y., under the management of Dr. Shew, and another at Brattleboro, Vt., under the management of Dr. Wesselhoeft, who, having explored the country from Florida to Maine, selected Brattleboro on account of the superior purity of the water of a spring there. At the present time there are in this country and Europe several hundred establishments in which the application of water in one form or another is the chief remedial agent relied upon in the treatment of diseases, but medicines in many cases are used to a greater or less extent. The name hydrophobia is not in general use among its practitioners, that of "hygienic medicine" being adopted instead.—Of books upon the subject may be mentioned, besides those above referred to, "Hydrophobic Encyclopædia," by R. T. Trall, M. D. (New York, 1852); "The Bath," by S. R. Wells (New York); and "Water Cure in Chronic Diseases," by J. M. Gully, M. D. (London).

HYDROPHOBIA (Gr. *ὕδωρ*, water, and *φόβος*, fear; Lat. *rabies canina*, canine madness), a rare but well marked disease in the human subject, characterized by excessive nervous excitement, the secretion of an unusually viscid saliva, a difficulty and sometimes a dread of swallowing liquids, and a rapidly fatal termination. It is caused by inoculation from the bite of a dog, already in a similar rabid condition. Although hydrophobia in the human subject is so infrequent that many practitioners of considerable experience have never met with a case, it is still of sufficient importance to merit serious attention, and to demand every possible precaution for its prevention; particularly since, when once developed, it is invariably fatal, no single well authenticated case of recovery having yet been recorded, and because the affection itself is so terrible in the distress suffered by the patient, and the horror

which it excites in the minds of the spectators. In France, with a population of 36,000,000, during the six years from 1853 to 1858 inclusive, there were 107 cases of hydrophobia, or one case annually for every 2,000,000 inhabitants. In the department of the Seine, with an average population of upward of 1,000,000, during the 40 years from 1822 to 1862, there were 94 cases, or a little more than $2\frac{1}{2}$ per annum. The greater proportional frequency of the disease in the metropolis and its immediate vicinity is no doubt due to the greater concentration of the population, both human and canine, which would of course be favorable to its communication from one animal to another and from animals to man. In the city of New York, with a population of 1,000,000, during the six years from 1866 to 1871 inclusive, there were 22 cases, or an average of $3\frac{2}{3}$ per annum.—When a man is bitten by a rabid dog, the wound does not differ in any visible character from that inflicted by a healthy animal. It is seldom severe and often slight, the animal frequently making only a single momentary attack. The wound thus made heals without difficulty, and is not especially painful or otherwise troublesome. In a majority of instances no further trouble comes of it. The danger from the bite of a rabid dog consists in the inoculation of the animal's saliva, which, owing to the disease under which he is suffering, contains a subtle but communicable organic poison. But there are various circumstances which may interfere with the poison's taking effect. First, the individual may be, habitually or at the time, insusceptible to its action. There is reason to believe that the human species as a whole are decidedly less susceptible to the poison of hydrophobia than dogs; and according to the experiments of M. Renault, at the veterinary school of Alfort, the proportion of dogs themselves, bitten by a rabid animal, who afterward become rabid, is not more than 33 per cent. Secondly, when the bite is inflicted upon parts of the body covered with clothing, the saliva, which is the only vehicle of the poison, may have been arrested by the garments and may not have come in contact with the wound at all. Thirdly, the poison may have been extracted from the wound immediately afterward, by the free discharge of blood, or by the instinctive manipulations of the wounded person, or may have been neutralized by surgical appliances. At all events, statistics seem to show conclusively that the bite of a rabid animal by no means invariably causes hydrophobia. M. Bouley, professor in the veterinary school at Alfort, estimates that in the department of the Seine no fewer than 100 dogs annually become rabid. In 25 cases of hydrophobia recorded at Alfort in the year 1861, 10 of these animals were known to have bitten 15 persons; that is, 15 bites had been inflicted by 25 rabid dogs. This would give, for 100 dogs annually affected by hydrophobia, 60 persons bitten during the same time. But

there are only from two to three cases of death from this disease annually in the department of the Seine; and, according to these results, not more than 3 in 60, or 5 per cent. of the persons bitten by rabid dogs, afterward become hydrophobic. But even this proportion of cases constitutes a terrible danger, considering the nature of the disease with which the individual is threatened.—For some time after the infliction of the wound no symptom manifests itself. The poison may have found its way into the tissues, but it is quiescent, and it remains so usually for several weeks. The exact period during which it may thus lie dormant, and afterward become fully developed, undoubtedly varies in different cases. Instances have been related in which hydrophobia has declared itself after an interval of several years, but these statements are evidently wanting in authenticity, and are almost universally regarded as extremely doubtful. It seems positive, however, that the period of quiescence may be extended to one year, and possibly to 17 or 18 months. Nevertheless these instances, if they exist, are very rare exceptions; and in the immense majority of cases the disease shows itself, if at all, between the end of the first and the end of the third month; so that after the lapse of three months from the date of the injury, the chances of escape increase rapidly with every succeeding week. By the end of six months the patient may be pronounced practically safe. When, however, the disease is to show itself, usually during the second or third month, its first manifestation is a sense of itching or discomfort at the seat of the wound. The cicatrix may become swollen and reddened, and a red line, following the course of the lymphatic vessels, is said to appear upon the limb, between the cicatrix and the trunk. This is the preliminary period of the disease, and may last for two or three days, rarely more than six, during which the patient is only slightly uncomfortable. Then the unmistakable signs of hydrophobia come on with great rapidity, and are aggravated from hour to hour. There is a feeling of stiffness about the neck, extending to the jaw and the base of the tongue. An indescribable anxiety and agitation of mind takes possession of the patient, often accompanied with paroxysms of momentary delirium and hallucinations. The breathing is hurried and irregular. There is great thirst; but there is also a difficulty of deglutition, apparently consisting in an irresistible spasm of the pharynx or glottis, which is so distressing that the patient sometimes rejects fluids after vainly attempting to swallow them, with violent demonstrations of irritation and despair. This is what has given rise to the idea that the patient dreads the liquid itself, and has unfortunately attached the name hydrophobia to the disease in question. The saliva becomes remarkably viscid and tenacious, and appears to add much to the distress of the patient, who endeavors constantly to detach it and expel it

from his mouth. This condition of nervous irritation rapidly exhausts the strength of the system, and death takes place, usually on the second or third day.—Such are the symptoms and course of hydrophobia in man. The treatment includes only a single measure, but this must be adopted at once on the receipt of the injury, and must be carried out in the most thorough manner. It consists in neutralizing the poison by cauterization of the wound. Some authorities recommend first cutting out the wound by an incision passing all round it through the sound flesh, and subsequently cauterizing the fresh surface. The objection to the procedure is that it requires some time and skill to perform it thoroughly, particularly as the wound is generally narrow and deep; and also that if the knife or the blood happen to penetrate the wound itself, they may become themselves contaminated with the virus and thus bring it in contact with a new and larger surface. It seems desirable to cauterize thoroughly the original wound without delay. Then, if thought proper, the eschar may be cut out, and the caustic again applied to the fresh surface of the new wound. On the whole, the particular caustic which is recommended by the highest authorities for this purpose is a solid stick of nitrate of silver. Its advantages are: 1, that it can almost always be readily procured; 2, that it can easily be cut into a form adapted to penetrate to the bottom of a deep and narrow wound; 3, that it readily dissolves in the animal fluids, and, when held for a few minutes in contact with the tissues, forms a tolerably deep and firm eschar, and coagulates thoroughly all the organic matters which may be present. It has been thought that during the period of quiescence the virus remains localized in the original cicatrix, and does not begin to disseminate itself through the system until the appearance of signs of irritation in the part. If this be so, it would of course be highly proper to cut out the cicatrix and cauterize the wound, in cases where this operation had not already been performed at any time between the receipt of the injury and the first manifestations of the disease.—But for the protection of the community from hydrophobia, the prevention of the bite of a rabid animal is much more important than its treatment. Any well educated surgeon, if within reach and called in time, will apply the proper remedies after the wound is inflicted. But he may not be applied to in season. The animal may not be suspected of rabies at the time of the injury; and even if everything be done for the sufferer which circumstances permit, he must still pass through several weeks or months of anxious uncertainty, until the extreme limit of possible incubation has been reached. The most important thing, in every point of view, is to diminish as far as possible the chance of a bite being inflicted at all; and by far the best means of accomplishing this object is to put the public on their guard by

an accurate knowledge of the symptoms of hydrophobia in the dog. The great danger at present consists in the fact that these symptoms are not usually recognized until after a wound has been inflicted; and animals may thus propagate the disease among their own species and communicate it to man at a time when they are not themselves known to be hydrophobic. There are three capital errors, commonly entertained by the public in this respect, which add very much to the danger spoken of: 1, that the mad dog has a horror of water and will not drink; 2, that he is liable to the disease more especially or exclusively in hot weather; and 3, that he always manifests a ferocious and aggressive disposition. Neither of these things is true; and the consequence is that a dog in cool weather, who is seen to drink freely, and is not especially ferocious, is looked upon without suspicion and treated with familiarity; and yet he may be hydrophobic and capable of inflicting a mortal wound, or of communicating a fatal disease by licking an abraded spot upon the hand of his master. It is evident, therefore, that it is of the greatest consequence that the true signs of canine hydrophobia should be recognized at an early period; for as soon as a dog is known to be rabid, there is but little danger of his being allowed to bite. Rabies in the dog may occur at any season, and is not more likely to show itself in warm than in cool weather. Consequently all police regulations intended to suppress or exterminate hydrophobia, which are enforced in the summer months and suspended at other times, fail of their object, and may even do harm by inducing a fancied security during the cool season. According to the observations made by Prof. Rey at the veterinary school of Lyons, in France, the number of cases in that district was greater during the rainy than during the dry months. Of 190 cases recorded at the veterinary school of Alfort, during the ten years from 1853 to 1863, the following list shows the aggregate numbers in each month of the year, arranged in the order of their frequency: In April, 25; March, 21; January, 20; June, 18; May, 16; August, 16; September, 16; November, 14; July, 12; December, 12; February, 10; October, 10; total, 190. The first symptoms of hydrophobia in the dog, as described by Youatt and Bouley, consist in a gloomy and sombre disposition, together with a nervous agitation and disquietude, which is betrayed by frequent changes of position. The animal, usually cheerful and desirous of companionship, seeks to avoid his master or his playmates. He skulks into his kennel, into a closet, into the corners of the enclosure, underneath pieces of furniture, and endeavors to escape notice. If called out, he obeys, but slowly and unwillingly, and as soon as possible again betakes himself to his retreat. In a few minutes he is dissatisfied with it, and leaves it for another. Then he goes back to his litter, and takes it apart or arranges it in a

variety of ways, without being able to suit himself with any. The expression of his eye is suspicious and uneasy; and in a few minutes he is again wandering from place to place. Now these signs, when taken singly, are not decisive indications of rabies. It is natural to the dog, when suffering under almost any temporary illness, to withdraw himself from observation, and seek a retreat in some dark corner; but he generally remains there quiet until he begins to recover. It is this desire to avoid observation, combined with an incessant restlessness, which is peculiar to commencing hydrophobia; and whenever an animal shows these two symptoms together, moving constantly from place to place, and searching in every corner as if looking for something which he never finds, he should at once be an object of suspicion, and properly watched until his malady either disappears or becomes distinctly pronounced. The next sign of hydrophobia is that the animal has slight and temporary attacks of hallucination. He thinks he hears a sound or sees an object which does not exist. This condition is fully recognized by veterinary experts, although its signs are often overlooked by others. The dog suddenly pricks up his ears and runs to a particular spot, as if he had heard a noise on the other side of a door or partition. Sometimes he will snap at the empty air, as if he were catching a fly. Sometimes he will stand immovable and attentive for a few moments, as if he were listening or watching for something which is only an illusion. These signs are exceedingly important, and should redouble the vigilance of those having charge of the animal, who should from this moment be kept in a position to prevent his doing an injury. All this time the animal may show no disposition to bite. A rabid dog often varies in this tendency according to his individual character. The evidence of all the best observers shows that a dog, naturally good-tempered and mild in disposition, will sometimes refrain from biting until very late in the disease. Furthermore, the same dog will often show no tendency to bite his master, for whom he still retains his natural affection, but may at the same time be easily provoked by a stranger. This circumstance forms one of the most insidious sources of danger in the case of a rabid dog not yet known to be such. Even the master may be misled by finding the animal submissive as usual to his word, and even to a slight correction, while a second blow or a threatening gesture may be followed by a sudden and ungovernable attack on the part of the animal, and the infliction of a fatal wound. During all this period, furthermore, and also during the entire course of the disease, there is no hydrophobia in the strict sense of the word. The rabid dog has no horror of water, and he does not refuse to drink. On the contrary, he drinks frequently, and when, the disease being fully established, the constriction of the fauces renders deglutition

difficult, he no less endeavors to satisfy his thirst, sometimes by plunging his muzzle deeply under the surface of the water. No single error in regard to the disease is more unfortunate than this; for when a dog drinks, the bystanders conclude that he is not hydrophobic, and consequently overlook the other symptoms which might indicate the nature of the malady. The rabid dog does not at first refuse his natural food, but soon ceases to take it with his accustomed relish. An important sign, however, is an unnatural or depraved appetite. The animal gnaws and even swallows all kinds of indigestible substances. Pieces of wood, bits of stone, furniture, clothing, the stuffing of cushions, leather, horse dung, and even his own excrements, are torn, gnawed, and swallowed. This is always a very suspicious circumstance. Some dogs are habitually mischievous in this respect, but even they only injure or destroy these substances; they do not swallow them. And particularly the disposition in question, manifesting itself in an animal to whom it is not habitual, and who is also evidently sick from some cause or other, should always put his owners upon their guard. Another symptom is now to be spoken of which is decisive and pathognomonic, namely, the rabid bark. It is difficult to give an accurate idea of this sound by mere verbal description; but the best authorities all agree that, when once recognized, it is entirely conclusive. The natural voice of the animal is altered. Instead of the usual succession of explosive sounds, equal in intensity and duration, it is hoarse, veiled, lower in tone, and begins with a single open bark, followed immediately by three or four diminishing howls from the bottom of the throat, during which the jaws, instead of closing completely at each bark, are only partly approximated to each other. Prof. Bouley says that both he and his pupils have been able to recognize distinctly the rabid dog by his bark alone, when the animal was not yet in sight, and was still at the other extremity of the courtyard of the Alfort veterinary school. The saliva is at first increased in abundance; but this symptom is of short duration, lasting, according to Youatt, not more than 12 hours, and is never so abundant as in the profuse salivation which attends an attack of epilepsy, a malady very common in dogs, but perfectly harmless. The true salivation of hydrophobia consists in a secretion of saliva which is scanty, but viscid and ropy, and which the animal endeavors to clear away from the mouth by the aid of his paws. This often gives the idea that he is annoyed by a bone accidentally lodged in his teeth; and fatal accidents have happened from attempting to aid the animal to get rid of the supposed annoyance. This preliminary period of the disease may last for one or two days. Now, however, comes the second and fully developed stage of the disorder, characterized by sudden paroxysms of fury, the true rabies

or canine madness. A very characteristic and important fact is that an animal in this condition is especially excited by the appearance of one of his own species. The sight of another dog drives him into an excess of sudden and immeasurable fury, followed by an immediate and aggressive attack. This often happens while he is still inoffensive toward other animals, and particularly toward his master. But it is a sign that the full development of his disorder is at hand, and in an hour or two afterward he may snap at every bystander indiscriminately, in the blind insanity of his excitement. At this time, or even at an earlier period, he often disappears from home, probably with the instinct of finding some more solitary place in which to hide. But meeting constantly with new sources of irritation, and his nervous excitability increasing at the same time, he becomes more furious, haggard, and threatening with every hour. He is now at the height of the disease. Wandering along the streets or open highways, with head and tail drooping, his hide disordered and dusty, the ropy saliva hanging in strings from his open jaws, every man and animal that he encounters provokes him to a fresh attack. After 24 or 36 hours of this continuous excitement, without food or rest, and incessantly upon his feet, exhaustion begins to come on; his motions are less vigorous, his steps grow vacillating and irregular, and he no longer leaves the direct path, and offers violence only to those whom he unavoidably meets. At last, if not pursued and killed, a general paralysis takes possession of his system, and he dies exhausted by the intensity and continuance of the nervous agitation. The entire duration of the malady in the dog, from the first signs of disordered health until its fatal termination, is from two to six days. No distinct morbid change in any of the internal organs has ever been found after death, either in the dog or in man, which could be regarded as the pathological cause of this singular disease. Finally, the important symptoms of commencing hydrophobia in the dog, which should always be borne in mind, may be summed up as follows: 1, an unaccustomed gloomy and suspicious disposition, with nervous agitation and restlessness; 2, momentary attacks of hallucination both as to sights and sounds; 3, an unnatural and depraved appetite for indigestible or innutritious substances; 4, a peculiar and unnatural bark; 5, a ropy and viscid condition of the saliva, with dryness of the mouth and fauces; and 6, an insane and aggressive irritability of temper, most easily excited by the sight of other dogs, and at first manifested only toward them.—The best accounts of hydrophobia are to be found in the chapter on "Hydrophobia" in Gross's "System of Surgery" (Philadelphia, 1866); the chapter on "Rabies" in Youatt "On the Dog" (London, 1859); and Bouley, *Rapport sur la rage* (Paris, 1863).

HYDROSTATICS. See HYDROMECHANICS.

HYDROSULPHURIC ACID, Sulphydic Acid, or Sulphuretted Hydrogen, a gaseous compound first examined by Scheele in 1777; symbol, H_2S ; chemical equivalent, 34. It consists of two volumes of hydrogen and one of sulphur vapor condensed into two volumes, which form its combining measure. Its density is 1191.2, air being 1000. It is a colorless gas, has a slight acid reaction, and a most offensive odor, recognized in rotten eggs, dock mud, cesspools, many mineral waters, and putrefying organic matters containing sulphur. It extinguishes flame, but burns itself in contact with air with a blue flame, depositing sulphur. It is condensed by a pressure of 17 atmospheres at 50° into a colorless liquid, and was solidified by Faraday by cooling to -122° into a white crystalline translucent substance. Water absorbs $2\frac{1}{2}$ times its volume of the gas; alcohol 6 volumes. It blackens the salts of lead and of many other metals, forming sulphides of the metals. These being insoluble and made readily visible by their peculiar colors, even in minute quantity, the acid is a convenient test for determining the presence of the metals in solutions, and distinguishing them by the color of the precipitate and its other properties. Its aqueous solution and its solution in ammonia (hydrosulphide of ammonium) are among the useful chemical reagents. The gas is exceedingly noxious to inhale. Thénard found that a small bird would die in air containing $\frac{1}{3500}$ part of it, and a horse in air that contained $\frac{1}{350}$ of it. The gas is neutralized and decomposed by chlorine and iodine, which unite with its hydrogen; and the former, furnished by chloride of lime wet with strong vinegar, is a convenient antidote and disinfectant of the gas. Nitrate of lead, chloride of zinc, sulphate of iron, and sulphate of manganese are also efficacious in this respect. The presence of the gas is detected by its odor, and by its blackening a paper wet with a solution of acetate of lead. It is the cause of the discoloration of white lead paint in the apartments of houses, also of the blackening of silver spoons when these are used with boiled eggs, the albumen of the white of the egg furnishing the sulphur for the production of the gas.—To prepare hydrosulphuric acid, the ingredients employed are a ferrous sulphide, made by exposing to a low red heat 4 parts of coarse sulphur and 7 of iron filings, and diluted sulphuric acid. By pouring the acid upon broken lumps of the compound in a gas bottle, the gas is evolved, and may be collected in a bell glass over water at 80° or 90° , or over brine. It is absorbed by cold water. It may also be obtained by the action of hydrochloric acid upon antimonious sulphide. The reactions in each case are thus expressed: $FeS + H_2SO_4 = FeSO_4 + H_2S$. $Sb_2S_3 + (HCl)_6 = (SbCl_3)_2 + (H_2S)_3$.

HYDRUNTUM. See OTRANTO.

HYÈRES, a town of France, in the department of Var, on the S. declivity of a hill, 9 m. E. of Toulon, and 3 m. from the Mediterranean;

pop. in 1866, 10,878. The principal edifices are the old church, one of the most singular structures in France, and an ancient château, now used as a town hall. In the principal square is a column, surmounted by a white marble bust of the celebrated Massillon, who was a native of the town. Hyères is considered one of the healthiest winter residences in the south of France, and is much resorted to by invalids. Remains of an ancient Roman city exist in its vicinity. In the roadstead opposite the town, and belonging to it, is a group of small islands called the isles of Hyères (ancient *Stachades*), two of which are fortified. During the middle ages the place was called Hiedera, and was a favorite port of the pilgrims to Jerusalem.

HYGIEA, or Hygea, in Greek mythology, the goddess of health, a daughter of Æsculapius. She was represented by artists as a virgin in flowing garments feeding a serpent from a cup; the poets speak of her as a smiling goddess with bright glances, and a favorite of Apollo. By the Romans she was in time identified with the old Sabine goddess Salus.

HYGIENE (Gr. *ὑγιεινός*, healthy), the science and art of preserving health, by the appropriate nourishment of the body and the proper regulation of its surrounding conditions. The first subject of importance in a hygienic point of view is always the location or residence of the individual, family, or community whose interests are involved. Other conditions may be altered or modified with comparative readiness, but the place and character of the habitation, when once fixed, usually remain so for a considerable time, and thus exert a continued influence for good or evil. The habitation, when in the country, should always be placed upon such an elevation as to secure a thorough natural drainage. This is the first requisite; for there is no other single cause of disease so hurtful and insidious as the slow accumulation and stagnation of the refuse matters, in however small quantity, which are daily produced in and about an occupied habitation. Even standing pools, or hollow basins without an outlet, the result of a depression in the surface of the ground, should not be allowed in the immediate neighborhood of the house; for although it is only the rain water which at first collects in them, yet there is always more or less accumulation of organic matter from vegetable growth and from the aquatic animals and birds which make such places their resort; and as a pool of this kind is alternately filled and dried up, sometimes several times a year, the effluvia exhaled during this process will always become more or less injurious, and may be even dangerous to life. When a large number of inhabitants are collected within a small space, as in towns and cities, the question of drainage becomes of course still more important. The production of refuse materials is here exceedingly rapid, and corresponding provision should be made

for their immediate and complete removal. Besides the necessary provisions for drainage, the house and apartments should also be fully and completely ventilated. Effluvia and organic vapors of various kinds necessarily become developed in every occupied dwelling, from the daily culinary operations and the organic matters of the food and their remains. These effluvia are harmless when fresh; but they are subject to early decomposition, and at once become noxious if allowed to accumulate and stagnate. Every house, accordingly, should be swept throughout each day by a current of fresh air, sufficient to renovate its atmosphere and remove all vestiges of impurity. A free opening of the windows on opposite sides, early in the morning, is the best way of accomplishing this. In addition, each inhabited apartment should be constantly ventilated in such a manner as to remove the carbonic acid and other products of respiration, by open fires or other effectual means.—Proper clothing, adapted to the season and the degree of individual exposure, is also an important element of hygiene. There are few causes of disease more prolific than undue exposure to cold and dampness, and particularly to sudden changes of weather or draughts of cold air upon unprotected parts. The clothing should be so regulated, as a general thing, that the ordinary vicissitudes of the weather shall not be felt by the individual in such a way as to make a permanent impression upon the system. A sufficient suit of woollen underclothing is the best protection in this respect. It is important to remember, however, that for a person in health exposure to cold and dampness is seldom injurious so long as the body is in a state of muscular activity. It is remaining in a cold apartment in an inactive condition, or keeping on the wet or damp clothing after muscular exertion has ceased, that gives rise to dangerous consequences.—The quality and quantity of the food, and the regularity with which it is taken, are of the next importance in a hygienic point of view. The food, as a rule, should be simple in character, but nutritious, and each article of the best possible quality and properly cooked. An imperfect or careless mode of cooking may often injure materially the nutritious and digestible qualities of an article of food, originally of the best kind. Individual peculiarities are to be consulted in regard to the kind of food used by each person; certain articles being sometimes more or less indigestible for one person, which are quite harmless for another. The natural and healthy appetite is the best general criterion in regard to the quantity of food to be used, provided it be simple and nutritious in character. It is of great importance, finally, that the food be taken with regularity at the accustomed time, that it be properly masticated, and that its digestion be not interfered with by hurry, anxiety, or any unusual mental or physical disturbance at and immediately after the time of

meals.—A regular and sufficient bodily exercise should be taken every day to keep all the organs in a healthy state of activity. The exercise should be neither deficient nor excessive in amount; for bodily exertion which is so violent or so prolonged as to produce a sense of exhaustion and fatigue, instead of being beneficial to the system, is positively injurious to it. Neither can a deficiency of muscular exertion during one period be compensated by an excessive amount taken at another. It is the necessary and appropriate quantity of exercise, taken regularly day by day, which preserves the vigor of the system, and keeps it in a condition to resist the attacks of disease. The periods of exertion, furthermore, should alternate daily with periods of repose; and especially the natural amount of sleep should always be taken with regularity, and in apartments which are not too confined and the ventilation of which is properly provided for. It is during sleep that the main process of the nutrition and restoration of the nervous and muscular systems takes place; and if an individual deprive himself of sleep, wholly or even partially, for one or two nights in succession, he will invariably experience its damaging effects in the consequent temporary failure of the vital powers. An imprudence or neglect, like either of those mentioned above, may be counteracted in a strong and healthy person by subsequent care, so that he may recover from its immediate and more perceptible effects; but it is a principle which lies at the basis of hygiene, that causes of disease, however slight, by constant repetition day after day, or even at longer intervals, will certainly at last undermine the health, and produce a permanent and often irremediable injury. The easiest as well as the surest way of avoiding such a result is a constant and regular attention to all the necessary hygienic conditions. (See ALIMENT, BATH, DIETETICS, and GYMNASIICS.)

HYGROMETRY (Gr. *υγρός*, moist, and *μέτρον*, measure), the method of determining the amount of moisture in bodies, more especially in atmospheric air. A hygrometer is an instrument used for this purpose; and a hygroscopic is any substance that absorbs moisture from the air, and is in consequence changed in form or weight. Various salts absorb moisture and deliquesce, and are consequently called hygroscopic. These serve as hygrometers in chemical analysis; thus chloride of calcium placed in a glass tube absorbs the moisture from the air passed through the tube, and its increase of weight determines the quantity. The property is exhibited in hemp and cotton ropes, and in small fibres, as those of whalebone, and in hairs. Paper by absorption of moisture expands to such a degree that it is an imperfect material for preserving accurate plans. Its variation in length in extremely dry and in moist air sometimes exceeds 1 in 40. If a substance could be found which absorbed moisture in proportion to the quantity

in the air, and its form was proportionally affected thereby, this change could be readily indicated upon a dial, the extreme points of which are determined, the one by the least length produced by the greatest dryness, and the other by the greatest elongation caused by the most humid air that could be produced, the intermediate space being divided into 100 or other convenient number of degrees. Such an instrument would be a perfect hygrometer; but no such substance is known, and the properties of the same body in this respect are not constant at all times. The best instrument of this sort, which is after all only a hygroscope, was contrived by De Saussure. It is a human hair, cleansed by boiling in alkaline water. The zero point of the scale to which it is attached is fixed by drying the hair in air rendered by chemical absorbents as dry as possible; and then, by exposing it in a receiver to air saturated with moisture, the other extreme of the scale is found. The equal divisions between these are assumed to indicate proportional degrees of moisture or dryness. One end of the hair is fixed, and to the other is suspended a small weight. A grooved wheel or pulley carrying an index is placed so as to be moved by the hair as it contracts or expands. Various other hygrometers of this class have been devised, some on the principle of determining the moisture by the increased weight imparted to bodies by its absorption, and others by the torsion thereby induced in cords and in vegetable fibres; but all these methods have proved very imperfect.—Two other methods are to be noticed by which the humidity of the air is ascertained. The first depends on the determination of the dew point, or the degree of temperature to which the air must be reduced that its moisture shall begin to separate and condense upon cold surfaces. This difference alone is sometimes used to express the dryness of the air, as affording an indication of how near it is to its point of saturation. In temperate regions this sometimes amounts to 30° ; but in a dry and hot climate, under the lee of cold mountains which first strip the air of its moisture, it amounts to 60° or more; such is the case upon the hot plains of the Deccan, to which the air is brought from the other side of the Ghauts. Cooled down upon these to a low temperature, its moisture is precipitated in rain and snow, and when immediately after this it is raised to a temperature of 90° , it is found that no deposition of moisture again takes place until the temperature is reduced to 29° . The observation, however, is used to furnish more exact results. Tables have been prepared with the utmost care which give the elastic force of aqueous vapor at different degrees and even tenths of degrees of temperature, expressed in the height of a column of mercury sustained by the vapor. The temperature of the dew point of the air being ascertained, the elastic force corresponding to this temperature in the table represents the absolute humidity

of the air, and may be converted into the actual weight of moisture to the cubic foot under a given barometric pressure by the formulas prepared for this purpose, or directly by the tables constructed to reduce the labor of the calculation. By comparing the elastic force obtained from the table with that corresponding to the temperature of the air itself, the ratio between the two expresses the relative humidity of the air. This also is ascertained at sight by the tables specially constructed for this object. The most highly approved hygrometrical tables are those derived from the experiments of Regnault, made by direction of the French government to determine the expansive force of steam at different temperatures, which is also that of the vapor suspended in the air at the same temperatures. These tables are published in Regnault's *Études sur l'hygrométrie*, in the *Annales de chimie et de physique* (1845); and formulas also are given from which other tables, besides that of the elastic forces, have been prepared by others. The most complete series of these is furnished in the volume of "Tables, Meteorological and Physical," prepared for the Smithsonian institution by Arnold Guyot, and published in the "Smithsonian Miscellaneous Collections," 1858. In the same series is also presented the table of elastic forces of vapor deduced from the experiments of Dalton, together with others based upon it, and in general use in England. These are also found in Glaisher's "Hygrometrical Tables" (London, 1847), and in the "Greenwich Observations."—Various forms of the dew-point instrument or hygrometer have been devised. That of Prof. Daniell, which has been much used, is of the following construction: A bent tube, blown out at each end to a bulb, is laid across the top of a pillar, which serves as a stand, the two bulbs hanging down one on each side. One arm of the tube is long enough to contain a delicate thermometer, the bulb of which terminates in some ether contained in the external bulb. By boiling the ether before closing the tube the air is nearly expelled. When in use the empty bulb is covered with a piece of muslin, which is kept wet with ether. The evaporation of this condenses the vapor within, causing the liquid in the other bulb to evaporate and grow cool. The bulb becomes at last sufficiently cool for the moisture to condense upon it, and the instant this makes its appearance in the form of a ring of dew encircling the bulb at the level of the surface of the ether, the temperature is to be noted by the thermometer within, while that of the air is observed upon another thermometer attached to the stand. Another observation of the enclosed thermometer is made as the dew disappears by the bulb returning to its former temperature; and the mean of the two observations will give a close approximation to the dew point.—A better instrument is that of Regnault. Two glass tubes are suspended by a small tubular arm near the

top of each, both opening into the hollow stand that supports the tubes. A pipe for exhausting the air by means of a sort of bellows or the flow of water connects with the hollow in the stand by an opening near its base. The two tubes are closed, each with a cork through which a thermometer tube is fitted, the bulb in one reaching nearly to the bottom. Over the lower end of this one a very thin and highly polished thimble of silver nearly two inches long is fitted, and a fine tube open at each end is passed through the cork, reaching from the external air nearly to the bottom of the tube. Ether is poured into this bulb, covering the lower end of the thermometer, and rising an inch or two higher than the upper edge of the silver thimble. To determine the dew point, the apparatus for exhausting the air from the hollow stand is set in action. This causes the air to pass through the fine tube, and bubble through the ether, keeping it in motion and taking up its vapor. The liquid, the thermometer bulb, and the silver coating of the tube equally feel the reduced temperature, and the instant this reaches the dew point, the whole surface of the silver is covered with moisture. The temperature of the thermometer placed in the ether is then observed, while the other marks the temperature of the air. By stopping the current of air the temperature rises, and the moisture disappears from the silver. The thermometer is to be noted again, and the mean of the two observations taken for the dew point; or several trials may be made in rapid succession. To avoid affecting the result by the warmth radiated from the body, a small telescope may be used in reading the thermometer. The instrument has been modified by Prof. Connell in substituting for the tube a small flask of highly polished brass or silver, into the neck of which is secured an exhausting syringe.—The second of the two methods above referred to, by which the humidity of the air is ascertained, involves the determination of the temperature of evaporation; and the instrument used is the wet-bulb thermometer or psychrometer invented by Prof. August of Berlin, and described in his work *Ueber die Fortschritte der Hygrometrie* (Berlin, 1830). It consists of two delicate thermometers placed near together. The bulb of one is covered with muslin, which is kept wet by water supplied from a vessel close by through capillary conduction. The instrument is placed in a light draught of air, and as evaporation goes on the mercury in the wet-bulb thermometer sinks to a certain point; the temperature of both is then noticed. If the air was nearly saturated with moisture, the difference will be found to be very slight. The barometric pressure is observed at the same time, and data are thus afforded for calculating the elastic force of aqueous vapor in the air. The formula for this calculation, modified by Regnault, and the psychrometrical tables deduced from it, are given in the volume of tables referred to above, and are equally applicable to

the estimation whether the dew-point instrument or wet-bulb thermometer is used. To render them more convenient, they have been converted by Prof. Guyot into English measures. The series also contains tables of the weight of vapors in a given space at different temperatures. The method by the wet bulb, though regarded as decidedly the most convenient means of determining the elastic forces of the vapor, and thence the humidity of the air, is still rendered somewhat uncertain in its results from the impossibility of keeping the wet bulb uniformly moist, and from other causes also. The uncertainty of its results is indeed in some cases so great that Regnault in 1872 recommended that, for accurate meteorological purposes, resort should be uniformly had to the chemical methods of extracting and weighing the aqueous vapor in a given volume of air. To this end he has devised a simple arrangement by which concentrated sulphuric acid may be exposed to the atmosphere and absorb its aqueous vapor; a method that is specially applicable at very low temperatures.—The ultimate object of these hygrometrical investigations is, by enabling the meteorologist to ascertain at all times, in all localities, and at all accessible elevations, the true condition of the atmosphere as to moisture, to furnish him with accurate data for studying the laws which control its variations. The following table of relative humidity is prepared for every 5° F. from 5° to 95° above zero, and for a difference of temperature between the air and the dew point, technically called the complement of the dew point, ranging from 0° to 18°. (See DEW POINT, in article DEW.)

TABLE OF RELATIVE HUMIDITY OF THE AIR.

TEMP. OF AIR.	DIFFERENCE OF TEMPERATURE OF THE AIR AND OF THE DEW POINT.

HYKSOS, or *Shepherd Kings*. See EGYPT, vol. vi., p. 460.

HYLÆOSAURUS (Gr. *ὕλαϊος*, belonging to wood, and *σαῦρος*, lizard), the name given by Dr. Mantell to an extinct dinosaurian reptile, from the Jurassic strata of Tilgate forest, having the usual mammalian characters of its tribe, viz.: long bones with a medullary cavity, pachy-

derm-like feet, and sacrum of five united vertebrae. It attained a size of 20 to 25 ft., and was believed by Mantell and Buckland to have had an enormous dorsal dermal fringe like the

Hylaeosaurus.

horny spines on the back of the iguana; its skin was covered with circular or elliptical plates.

HYLAS, in Greek mythology, son of Theodamas, king of the Dryopes, and the nymph Menodice. Hercules, after slaying Theodamas, adopted Hylas, and took him on the Argonautic expedition. When they arrived at Mysia, Hylas went to a neighboring well for water, but the maids of that fountain became so fascinated with his beauty that they drew him into the water, and he was never seen again. When Hercules shouted for him, the youth's voice was heard from the well like a faint echo; and he was so enraged at his loss that he threatened to ravage the country of the Mysians if they did not produce Hylas dead or alive. They sought him in vain, and ultimately instituted an annual festival, during which they roamed over the mountains calling out the name of Hylas.

HYMEN, in Greek mythology, the god of marriage. According to some, he was a son of Apollo and one of the muses; but according to others, he was originally a mortal, who, having rescued some Attic maidens from Pelasgic pirates or other robbers, had his praises celebrated in token of gratitude in their bridal songs, which after him were called hymeneal songs. The practice of singing such songs at the nuptial season became in time universal, and the heroic youth was gradually elevated to the rank of a divinity. Hymen is represented in works of art as a tall handsome youth, carrying in his right hand a bridal torch.

HYMENOPTERA (Gr. *ὑμῖν*, membrane, and *πτερόν*, wing), a suborder of insects, so named from their four membranous, transparent wings. They have upper horny jaws for biting, and softer and longer lower jaws with the tip adapted for collecting honey; the females and neuters have a sting or piercer. All undergo complete metamorphosis; the larvæ of the stingers are soft, without legs, resembling maggots; most of the larval piercers resemble grubs and caterpillars. They are diurnal, swift fliers, and surpass all other insects in the num-

ber and variety of their instincts; of the very numerous species none are aquatic. They include the bees, wasps, ants, ichneumons, gall flies, saw flies, &c., which are described under their respective titles.

HYMETTUS, a mountain range of Attica, forming the S. E. boundary of the Athenian plain. It consists of two summits, the northern or greater Hymettus, the apex of which is about 3,500 ft. above the sea, and the southern or lesser Hymettus, denominated Anhydrus, "the waterless," by the ancients. The honey of Hymettus was considered by the ancient Greeks as inferior only to that of Hybla in Sicily; but at present, though still abundant, it is said to be of very poor quality. The excellence of its marble is a favorite theme with classic authors. The greater Hymettus is now called Trelo-Vuno; and the lesser Mavro-Vuno.

HYOSCYAMUS. See HENBANE.

HYPATIA, a Neo-Platonic philosopher, born in Alexandria about 370, killed in 415. She was the daughter of Theon, a distinguished mathematician and astronomer. She went to Athens near the close of the 4th century, and studied under the Neo-Platonist Plutarch, who expounded to a small circle of disciples the Chaldean oracles and the secrets of theurgy. On her return to Alexandria, her talents, beauty, eloquence, and modesty made her an object of admiration. She revived the school of Plotinus, and became its head. But both as a pagan and as a philosopher she provoked the hostility of Cyril, bishop of Alexandria. Not only was her lecture room thronged, but she was consulted by the most considerable persons of the city, among others by the prefect Orestes, who was at constant feud with the bishop. The city was a prey to the violence of parties, and it was to the influence of Hypatia that Cyril attributed the refusal of Orestes to come to a reconciliation. "Certain persons, therefore," says the ecclesiastical historian Socrates, "of fierce and over-hot minds, who were headed by one Peter, a reader, conspired against the woman, and observed her returning home from some place; and having pulled her out of her chariot, they dragged her to the church named Cæsareum, where they stripped her and murdered her. And when they had torn her piecemeal, they carried all her members to a place called Cinaron, and consumed them with fire." Hypatia was the author of two mathematical treatises, which are lost, and there remains from her only an astronomical table inserted in the manual tables of Theon. She is the heroine of Charles Kingsley's "Hypatia."

HYPERBOLA (Gr. *ὑπερβάλλειν*, to transcend), one of the conic sections, produced when the cutting plane makes a smaller angle with the axis of a right cone than is made by the side. The shadow of a globe on a flat wall, when part of the globe is further than the luminous point is from the wall, gives a hyperbola. Hyperboloids are surfaces generated by moving hyperbolas.

HYPERBOREANS (from Gr. *ὑπέρ*, beyond, and *βορέας*, the north wind), a legendary race, placed by the Greeks in the remote regions of the north. They first appear in Hesiod and in the traditions connected with the temples at Delphi and Delos. The poets conceived of them as dwelling in perpetual sunshine, possessing abundant fruits, abstaining from the flesh of animals, and living for a thousand years. The supposed location of the Hyperboreans changed with the progress of geographical knowledge. At first placed in the north at the sources of the Ister (Danube), they were transferred by some to the west when this river was supposed to proceed from the western extremity of Europe; while others transferred them to the extreme north of Europe, beyond the mythical Gryps and Arimaspi, who themselves dwelt beyond the Scythians. The latter view at length prevailed; the character of the Hyperboreans as a sacred nation was lost sight of; and their name became only a geographical expression for the extreme north. Modern ethnologists designate as Hyperboreans a subdivision of the arctic races, inhabiting N. N. E. Asia. (See ETHNOLOGY.)

HYPERIDES, one of the ten famous Attic orators, born probably about 395 B. C., died in Ægina in 322. He was a pupil of Plato in philosophy, of Isocrates in oratory, began his career as an advocate, and was an associate of Demosthenes as leader of the anti-Macedonian party. In 358 he and his son equipped two triremes at their own expense to join the expedition against Eubœa. He displayed an equal interest in the patriotic cause on an embassy to Rhodes (346), in the expedition against Byzantium (340), as ambassador with Demosthenes to Thebes after the capture of Elatea by Philip (338), and after the battle of Chæronea, when he proposed, by a union of the citizens, resident aliens, and slaves, to organize a desperate resistance to Philip. For his efforts on the last occasion he was prosecuted on an indictment for illegal proposition, but was acquitted. Of his defence there remain only the words: "The Macedonian army darkened my vision; it was not I that moved the decree, but the battle of Chæronea." The affair of Harpalus (324) for the first time broke his friendly relations with Demosthenes, against whom he appeared as public prosecutor. On the report of Alexander's death (323), it was chiefly by his exertions that the confederacy was formed which brought about the Lamian war. He fled after the battle of Crannon to Ægina, and was pursued and put to death by the emissaries of Antipater. The number of orations attributed to him was 77, but the ancient writers rejected 25 of them as spurious. They agree in extolling his genius, and commend him for almost every excellence of style. Until lately only unimportant fragments of his orations were known to have been preserved. In 1847 A. C. Harris, an English resident of Alexandria, purchased near the ruins of Thebes some

fragments of papyrus written over with Greek, which were parts of the oration of Hyperides against Demosthenes on the charge of having been bribed by Harpalus. He published a facsimile of them in 1848. They were edited by Churchill Babington, with an introduction and commentary, in 1850. Another Englishman, Joseph Arden, procured at the same place and nearly at the same time other fragments of papyrus, which were found to contain a large part of his speech for Lycophron, prosecuted for adultery, and his complete oration for Euxenippus, charged with making a false report of the oracle of Amphiaraus. These were edited by Mr. Babington in 1853. Another traveller, Mr. Stodart, brought from Egypt in 1856 another collection of papyrus fragments, among which were a large part of the funeral oration on Leosthenes and the Athenian soldiers who perished in the Lamian war. This was published by the same editor in 1858. His orations have been republished in Germany by Böckh, Kayser, and others, and in Paris in Didot's *Bibliotheca Græca*. The funeral oration has been edited by Cobet (Leyden, 1858).

HYPERTROPHY (Gr. *ὑπέρ*, over, and *τροφή*, nourishment), an excess of growth of a part without degeneration or alteration in the structure; the exact opposite to atrophy. Hypertrophy may depend on the excess of the materials of certain tissues in the blood; when this fluid contains habitually too much fat, there may be an abnormal increase of the adipose tissue; similar hypertrophy may thus be induced in other tissues, but there is no evidence that the muscles or nerves increase in bulk from the mere excess of their formative materials. Though an increased supply of blood is generally rather the consequence than the cause of excessive nutrition in a part, hypertrophy may arise from a mere increased circulation, and when one kidney cannot perform its functions, the other has been known to increase in size, owing to its increased activity as an excreting organ. This must be distinguished from the augmented bulk of long congested parts, in which there is not normal hypertrophy, but an addition of altered and inferior tissue. Hypertrophy is in most cases dependent on a preternatural formative capacity in the part, sometimes congenital (as in the abnormal growths of fingers and toes, and even entire limbs), but generally acquired. The most striking instances of acquired nutritive activity are seen in the muscular system, consequent upon the excessive exercise of its functional powers. Muscular hypertrophy is most often seen in the involuntary muscles, whose action is in some way impeded; thus stricture of the urethra or stone in the bladder, obstructing the exit of the urine and calling for extra exertion to expel it, causes hypertrophy of the muscular coat of the bladder; so it happens with the gall bladder when its ducts are stopped by calculi, and with the intestines when a stricture exists in any portion. Hyper-

trophy of the ventricles of the heart is often dependent on narrowing of the cardiac orifices by disease of the valves, giving the organ double work to do, and increasing its activity, as in other muscles. (See HEART, DISEASES OF THE.) When any of the voluntary muscles are specially exercised, hypertrophy is observed in them, as in the arm of the blacksmith or the legs of a professional dancer; and such hypertrophied muscles generally cause an increased nutrition of the bones to which they are attached, and an enlargement of the points of origin and insertion. There are certain enlargements of glands, in which their proper tissue is increased without structural change, which unite physiological hypertrophy with pathological tumors, as in the case of the mammary, thyroid, and prostate glands. Certain tumors of the uterus contain only an excess of the normal muscular and fibrous tissues of the organ, and yet cannot be regarded as examples of hypertrophy, as they observe no regular growth, subservise no physiological purpose, and constitute a positive deformity and disease; such abnormal growths may exist upon a uterus itself hypertrophied from increased functional activity, and must not be confounded with the latter. Supernumerary parts, as additional fingers and toes and various outgrowths developed during foetal life, must in like manner be referred to local hypertrophy from excess of formative activity. Dr. Carpenter sees in this whole series of abnormal production the operation of a similar power; that which in simple hypertrophy is confined to increasing the size of an organ by the development of new tissue according to the morphological type of the part, in the formation of supernumerary tissues also imparts to them an independent existence; on the other hand, while in ordinary hypertrophy the tissues in excess are incorporated in the affected organ, in the structure of a tumor the perfectly formed and independently growing tissues constitute a mass whose shape is determined more by surrounding conditions than by any tendency of their own—the formative power undirected by the normal morphological *visus*. In malignant growths, the development of tissues stops short of the limit by which formative power produces the normal tissues, and their vital endowments are not sufficient to resist the tendency to degeneration.

HYPHASIS, a river of ancient India. See PUNJAB.

HYPOCHONDRIASIS (Gr. *ὑπό*, under, and *χόνδρος*, cartilage), a disease generally classed among neuroses, characterized by derangement of various organic functions, and accompanied by an habitual sadness, often bordering on despair, and a disposition to exaggerate every trifling symptom into a sign of dangerous malady; probably so called because it was formerly attributed to disorder of the spleen, an organ situated in the left hypochondrium. It occurs principally in persons of melancholic

temperament, and in those whose moral and intellectual faculties have received high and unnatural development; it is said to be common in proportion to the elevation of the human mind and to the progress of civilization. Men of letters, overtaken students and men of business, and those whose naturally delicate constitutions and ardent imaginative minds have been abnormally stimulated, are the most frequent subjects of hypochondria; but it may arise at any age and in the strongest persons after profound grief or other moral emotion, whether of love, hope, jealousy, or fear, debilitating excesses of any kind, the suppression of any habitual discharge, a sudden change of habits of life, or unceasing devotion to any philanthropic, political, or intellectual pursuit. The symptoms are as various as its causes and the constitutions of men; there is not a part of the body which may not be the subject of the hypochondriac's complaint; the senses are ordinarily very acute, and the sight, hearing, smell, taste, and touch are preternaturally excitable, and the sources of great real or imaginary suffering from the slightest causes; there is almost always digestive disturbance, which enters largely into the explanation of the causes; without fever or local lesion, the sensibility is exalted, with flatulence, nausea, spasms, palpitations, illusions of the senses, aches and pains simulating most diseases, fear of trifling dangers, exaggeration of all the moral sentiments, extreme instability of conduct, and anxiety in regard to the health. The head is full of painful sensations, as fugitive as passing clouds, agonizing at one moment and forgotten the next; sleep is disturbed and unrefreshing, and the waking hours rendered miserable by imaginary troubles. Expressing complete disgust with life, the sufferers yet run to the physician with an account of every fugitive pain, and consider themselves neglected if not listened to, and insulted if their ailments be called imaginary. Both sexes suffer from hypochondria, and the female specially in the reproductive system. Though in the beginning the disorder may have been wholly in the digestive organs, and that only of a functional and curable character, by constant and morbid attention to these and other fancied ailments real and organic disease may be produced, and a return to health be impossible. It is generally slow in coming on and of long duration, and is not incompatible with long life; if the digestion be tolerably good, the prognosis is favorable, as such persons are apt to observe most rigidly the ordinary rules of hygiene; in some impressionable but resolute natures, it degenerates into a settled melancholy, which a slight cause may convert into temporary insanity and suicidal mania. It cannot be said to have any special organic lesions, though in severe and fatal cases there have been found various alterations of the digestive, circulating, and nervous systems. There are two opinions as to the nature and

seat of hypochondria: one is that it is an irritation of the nervous system which presides over the digestive organs, with or without gastro-intestinal inflammation; and the other that it is a cerebral neurosis, a kind of melancholy, as proved by the constancy of the cerebral symptoms and the efficacy of moral methods of treatment. Some modify the latter opinion by tracing it to a disturbance of the intellectual powers, which acts upon and impedes the functions of all the organs by concentrating the whole nervous energy in turn upon each system, organic lesions following upon the neurosis and displaying the morbid symptoms peculiar to each. As a general rule the disease is of far less moment than the formidable array of symptoms, the complaints of the patient, and the expression of suffering would indicate; sometimes deceitful, and their feelings misinterpreted both by themselves and the physician, irritable, suspicious, and versatile, hypochondriacs are exceedingly troublesome and unsatisfactory patients. Children of hypochondriac parents, if they show any signs of uncommon nervous susceptibility, should be educated in a manner calculated to diminish the preponderance of the nervous element, and to increase the physical strength, as by avoiding excess of study and all excitement, cultivating the generous sentiments, and by gymnastic exercises; in this way the ranks of hypochondriacs would be much lessened. Attention to the causes, when these can be ascertained, and their removal as far as possible, the observance of hygienic rules adapted to circumstances and constitutions, avoidance of excess in eating and drinking, and perhaps an occasional laxative or a tonic course, are probably all that can be done in the way of treatment. But in order to be of any benefit to his patient, the physician must secure his confidence, and accustom him to the belief that his affection is understood, his feelings appreciated, his sufferings commiserated, and his complaints attentively listened to; having inspired this confidence, it is not difficult to lead even the most confirmed hypochondriac to change his stereotyped way of regarding men and things, to interest him in new enterprises and modes of thought, and by judicious management to put him in the way of a return to health by following the dictates of his own feelings and common sense.

HYPOPHOSPHITES. The salts formed by hypophosphorous acid with lime, soda, potash, and ammonia were proposed, mainly on theoretical grounds, as remedies for phthisis, by Dr. Churchill of Paris. They have been extensively used, and are so still to a much less degree. Although possibly useful as tonics in some cases, they are as far as all other drugs from being specifics for consumption. Their chief therapeutic value is to be found in cases where the phosphates of the system are morbidly deficient. This occasionally occurs in the debility that sometimes follows prolonged lactation, in some forms of dyspepsia and anæmia, and now and

then in the disturbance or fever of dentition. The hypophosphites of soda and lime are the most useful agents, medicinally, of this class. They are best given in combination with a bitter or aromatic tincture or infusion. The dose of each of them is from 2 to 12 grains, according to age and other circumstances.

HYPOSULPHATES, and Hyposulphites, compounds, the one of hyposulphuric and the other of hyposulphurous acid, with bases. Of these salts the only one of much interest is the hyposulphite of soda, which possesses the property of readily dissolving the chloride, bromide, and iodide of silver. It has been of great service in the preparation of daguerreotypes and photographs, being used to dissolve the sensitive salt of silver which remains unchanged after its exposure in the dark chamber of the camera. In chemical analysis also it is employed to distinguish between the earths strontia and baryta, precipitating the latter from its solutions, but not the former. It has moreover been adopted as a medicine, and been found beneficial in cutaneous affections, in visceral obstructions, and in disease of the stomach attended with yeasty vomiting. The salt is prepared as follows: A pound of dry carbonate of soda, finely pulverized, is mixed with five ounces of flowers of sulphur, and the mixture is slowly heated until the sulphur melts. By constant stirring exposed to the air the sulphide of sodium, which first forms, is converted into sulphite of soda. This is dissolved in water and filtered. The hot solution, concentrated by boiling, is then saturated with sulphur and allowed to cool, when it deposits large transparent crystals, which are the hyposulphite of soda, of composition represented by the formula $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$. These are soluble in water, but not in alcohol. The hyposulphite of soda is the anti-chlor employed by paper makers for removing the last traces of chlorine from the bleached pulp. A delicate test for the presence of hyposulphurous acid is the brown red color produced by a few drops of perchloride of iron.—The hyposulphites, and especially the hyposulphite of soda, have been used in medicine for the destruction of animal and vegetable parasites and the arrest of fermentation. The diseases to which they have been applied are not only those which are demonstrably connected with parasitic growth or fermentation, as yeasty vomiting and parasitic affections of the mouth and skin, but also those where similar processes may be supposed to be essential factors; such are intermittent and other forms of malarial fevers, typhoid, purulent infection, glanders, cholera, and the contagious exanthemata. Although favorable reports have been made of their action, general experience does not as yet appear to justify the hopes founded on theory, or the confident expectations of the physician most widely known as the originator of the treatment, Dr. Polli of Milan. No harm, however, has resulted from them, and the presump-

tion in their favor is strong enough to justify their employment in connection with other treatment. The hyposulphite of soda may be given in doses of 10 or 20 grains, or more, three times a day, dissolved in water. The action of the sulphite is identical with or analogous to that of the hyposulphite, and it has been used for the same purposes.

HYPOTHECATION (Gr. *ὑπό*, under, and *θήκη*, a chest), a word which, in the Roman civil law, from which it is taken, signifies more nearly what we understand by mortgage than by pledge, for which they had a separate word, *pignus*; but it is not precisely the same as either. It was generally used whenever the title to property was transferred by the owner to his creditor, by way of security for the debt, but without that delivery of actual possession which was necessary to constitute a pledge. In English and American law, the word is most frequently used in the law of shipping.

HYRAX, a small pachyderm, coming nearest to the rhinoceros family, but looking much like a diminutive hare, and in some respects seeming to form one of the connecting links with the rodents, constituting the family *Lamnungia* of Illiger. The old naturalists had always placed it among the rodents, but Cuvier, from its anatomical structure, ranked it with the pachyderms, of which Swainson calls it the gliriform type. The number of ribs is 21 pairs, greater by 6 than in any rodent, of which 7 are true; the sternum consists of 6 pieces; there are no clavicles; the suborbital foramen is small; the dental formula is: incisors $\frac{2}{2}$, canines none, molars $\frac{4}{4}$ or $\frac{3}{3}$, with distinct roots; the extinct pachyderm *toxodon* has long and curved molars, without roots, and incisors with arched sockets, forming another link in the chain of rodent affinities in this order. The toes are four before and three behind, as in the tapir; the hoofs are small and flat, but the inner toe of the hind foot has a curved claw. The genus *hyrax* (Hermann) is the only one in the family, and contains four or five species. The body is covered with short, thick fur, with a few long bristles scattered among the shorter hair, and others around the nostrils and orbits; a tubercle in the place of the tail. The common name of the species is daman; it seems to bear the same relation to the rhinoceros as the existing sloths to the extinct megatherium; it lives among rocks, and is sometimes called rock rabbit and Cape badger. The Syrian hyrax (*H. Syriacus*, Schreb.) is about 11 in. long and 10 in. high; the upper parts are brownish gray, the sides yellowish, and the lower parts white. Its movements are quick, and its habits much like those of rodents; it delights in heat, in cold weather rolling itself up; it searches for narrow openings in which to hide itself, as its soft feet are not adapted for digging burrows like many rodents; its sense of smell is acute, and by it the food, which is wholly vegetable, is obtained; it is of mild disposition, with little intelligence

and little fear. It is found on the mountains near the Red sea, and in Ethiopia and Abyssinia in caverns in the rocks, dozens being seen at a time warming themselves in the sun. This animal, according to Bruce, is called in Arabia and Syria Israel's sheep, and is the

Hyrax Capensis.

shaphan of the Hebrews, generally translated rabbit or cony. The Cape hyrax (*H. Capensis*, Pall.) is about the size of the rabbit, but with shorter legs, more clumsy form, thick head, and obtuse muzzle; the color is uniform grayish brown, darkest along the back; it lives in the rocky regions of the south of Africa; its flesh is delicate and savory. Other species are described in the woods of Africa.

HYRCANIA, an ancient country of Asia, comprising the western portion of the mountain region between the S. E. shores of the Caspian (sometimes called the Hyrcanian sea) and the river Arius (now Heri-rud). It consisted mainly of the valleys of the Nika, Gurgan, and Atrek. It was a most productive country, capable of sustaining a dense population, and deserving Strabo's description of being "highly favored of heaven." The Hyrcanians seem to have been a people of Turanian race, intermixed with Aryans. After a short resistance they submitted to Cyrus. When the Persian empire was organized by Darius Hystaspis into satrapies, Hyrcania was added to the satrapy of Parthia. After the Macedonian conquest, Hyrcania became a part of the empire of the Seleucidæ. The Parthian king Arsaces II., or Tiridates, detached it from the Syrian empire and added it to his own territories. Shortly afterward it was invaded and devastated by Scythians. It was also invaded by Antiochus the Great, in his Parthian war, but seems to have remained unsubdued. A subsequent revolt against the Parthian rule was unsuccessful.

HYRCANUS. **I. John**, a Jewish high priest, died in 106 (or according to some in 105) B. C. He succeeded his father Simon Maccabæus in the high priesthood as one of the Asmonean rulers of Judea, 135 B. C. In that year Antiochus Sidetes besieged Jerusalem, and obliged the inhabitants to dismantle its fortifications and pay a tribute; but after the defeat and death of Antiochus in 130, Hyrcanus reestablished his independence and extended his dominion. He razed the city of Samaria,

took several other cities from the Syrian kingdom, and not only conquered the Idumæans, but compelled them to submit to the Mosaic ritual. He also formed an alliance with the Romans. In the latter part of his reign he abandoned the sect of the Pharisees for that of the Sadducees, thereby incurring much odium. He was succeeded by his son Aristobulus, who took the title of king of Judea. **II. Hyrcanus II.**, grandson of the preceding, born about 109 B. C., beheaded in 30. He was the eldest son of Alexander Jannæus and his wife Alexandra, daughter of John Hyrcanus. On his mother's death (71) he succeeded to the kingdom, but the power was soon wrested from him by his younger brother Aristobulus. When Pompey made himself master of Jerusalem in 63, he reinstated Hyrcanus in the government as a tributary prince. Dissensions again deprived him of power, but when Cæsar reconstructed the state he was once more restored as high priest, Antipater having civil authority as procurator. Herod, the younger son of Antipater, succeeded his father as procurator, and betrothed himself to Mariamne, the granddaughter of Hyrcanus. In a new attack by Antigonos, the only surviving son of Aristobulus, who was aided by the Parthians, Hyrcanus was taken prisoner; his ears were cut off to render him incapable of holding the office of high priest, and he was banished to Babylonia, where the Parthian monarch and oriental Jews treated him with distinction. After some years he returned to Jerusalem, where Herod had now established himself in the sovereignty and had married Mariamne. Becoming jealous of his claims to the throne, Herod caused him to be put to death.

HYRTL, Joseph, an Austrian anatomist, born at Eisenstadt, Hungary, Dec. 7, 1811. He studied at Vienna, became in 1837 professor of anatomy at Prague, and was recalled to Vienna in 1845 in the same capacity, became rector of the university, and retired March 16, 1874. He is distinguished for his labors in comparative anatomy, his investigations on the organ of hearing, and the invention of many anatomical instruments. He was the first to introduce a knowledge of topographical anatomy into Germany, and published a manual relating to this branch of science (2 vols., 1847; 5th ed., 1865). His *Lehrbuch der Anatomie des Menschen* (1847; 11th ed., 1870) is a text book in German universities, and has been translated into many foreign languages. Among his other principal works are *Handbuch der praktischen Zergliederungskunst* (1860), an elaborate description (1865) of the museum of comparative anatomy, which he had founded, and *Das Nierenbecken der Säugethiere und des Menschen* (Vienna, 1870). His preparations, famous for many years, demonstrate by colored material injected through some of the principal arteries the presence of the microscopic arteries and veins accompanying the lacteal vessels in the minute intestinal papillæ. By the same means

he demonstrated in 1874 the presence of a vascular net in the cornea of the eye, and after many ineffectual attempts he succeeded in filling the arteries and veins of an infant eight days old from the umbilical vein with coloring matter so perfectly as to reach and penetrate the minute arteries and veins of both corneæ.

HYSSOP (*hyssopus officinalis*, Linn.), a perennial aromatic plant, of the natural order *labiatæ*, a native of Europe, and cultivated there and in the United States in gardens. Its flowers, violet-colored or blue, and its leaves, are used in medicine, though but little by regular practitioners. It is a warm and gentle stimulant, promotes expectoration of the mucus, and is used in chronic catarrhs, especially by old people. The hyssop of Scripture is the caper tree, *capparis spinosa* (Linn.), which abounds in the south of Europe, in lower Egypt, and in Syria.

HYSTERIA (Gr. *ὑστέρα*, womb), a disease characterized by great excitability of the nervous system, especially of the sensory ganglia, without necessary structural lesion, and manifested by disordered states of the emotional nature, with loss of the power of controlling the thoughts and feelings, by spasmodic symptoms, and occasionally by perversion or suspension of the intellectual faculties. It received its name from the idea that it is peculiar to the female sex, originating in some disturbance of the uterine functions; but, though by far the most common in females, and generally connected with disorder in the generative system, it may also occur in males; a common name for it is "the vapors." The nervous symptoms predominate, varying in character and intensity according to the temperament of the individual, the nature of the causes, and the persistence of the disease. In the beginning it generally manifests itself by an exaggeration of the ordinary signs of emotional excitement, such as smiles and tears, irrepressible laughter and convulsive sobs, brought on by trifling causes; the nervous excitability increases, until violent convulsions of an epileptic or tetanic character arise from slight stimuli, with coma, opisthotonos, trismus, paralysis, cramps, ending often in monomania or moral insanity. The paroxysms are sometimes of frightful intensity, requiring the strength of several persons to restrain a delicate female and prevent self-injury; after an attack the patient may be exhausted and almost insensible, and in a state of double consciousness, or much agitated, laughing or crying at the strangest fancies; at times the person falls insensible, breathing at long intervals, recovering with a sense of fatigue and coldness, or with involuntary emission of limpid urine. In cases where the nervous symptoms are less prominent, there are pain and a sense of heat and fulness in the region of the uterus, constriction of the throat with difficulty and increased desire of swallowing, a feeling as if a ball were rolling from the abdomen up to the epigastrium and throat with a

sensation of pressure and suffocation, flatulence and tympanitic distention, hurried respiration, palpitations, occasional cramps, and great depression or exaltation of spirits. An attack of hysteria may last for several hours, the violent symptoms recurring every few minutes, with intervals of partial rest; or it may consist of but a single paroxysm of 20 minutes or half an hour in duration. After the paroxysm has ceased, tolerable health may be enjoyed for some time, though the nervous excitability persists. In cases of long duration, the intellect and memory become enfeebled, the strength fails, and hypochondriasis and various chronic irritations of the vital organs supervene. Hysteria is very irregular in its march; it is the most protean of diseases, simulating almost every morbid condition; its duration is variable, sometimes terminating in health after a few attacks without medical treatment, and at others lasting a lifetime in spite of the best directed efforts to arrest it; its most dangerous consequences are convulsions, spasmodic contractions, partial paralysis, epilepsy, and tendency to insanity. The predisposing causes of hysteria are the female sex and a hereditary or acquired nervous irritability; the exciting causes are vivid moral emotions, anything which excites the imagination, especially disappointed love, jealousy, and various excesses of body or mind; it is often brought on by the mere force of imitation; some irregular action of the sexual functions is found in nearly if not quite all cases between the ages of 15 and 50. There has been great diversity of opinion on the nature and seat of the disease; its cause has been located in the uterus, in the brain, in the spinal cord, and in the stomach and other abdominal organs. Whatever be its origin, a disordered state of the emotional nature is an essential character of hysteria, and the control of the feelings rather than of muscular action is lessened or lost; it is partly a disease of the mind, from improper education or self-abandonment to the power of the emotions. The habitual indulgence of feelings of a painful character or of sexual tendency affects the nutrition of the nervous and genital systems, giving rise to the peculiar phenomena of this affection. Though hysteria may simulate the phenomena of epilepsy, tetanus, chorea, hydrophobia, and other nervous diseases presented to its imitative disposition, it is dependent on a state of much less abnormal character; there is generally no structural lesion, nor any serious disturbance of the nutritive functions, as is

evident from the long duration of the disease, and the suddenness with which different forms pass into each other or disappear entirely; the strangeness of these combinations and sudden changes is sufficient to distinguish hysteria from the more grave diseases which it imitates. According to Carpenter, this excitability of the nervous system, which is only an exaggeration of that characteristic of the female sex, is caused by some defect of nutrition, the particular phenomena arising either from some morbid condition of the blood acting upon the nervous centre most susceptible to its influence, or from irritation of the peripheral nerves; he believes a gouty diathesis is one of the most frequent sources of this imperfect nutrition.—The principles of treatment are threefold: 1, to improve the nutrition of the nervous system by bringing the blood up to its healthy standard by strengthening diet, hygienic means, and the judicious employment of tonics; 2, to remove all irregularities in the menstrual or other functions, when they are evident exciting causes; 3, to act upon the mind, by leading the patient to repress the first emotional excitement by the force of the will, and to direct the attention to a different class of objects, substituting a pleasant for a disagreeable train of thought. The attack itself requires that the patient should be kept from injuring herself, and the removal of all constricting garments, fresh air, sprinkling with cold water, inspiration of ammonia or other strong or disagreeable odors, irritating the nostrils with a feather, and other similar domestic remedies. To prevent a return, tranquillity of mind and habits of self-control are the best remedies; any disappointment, whether in love, business, or other affairs of life, should if possible be removed by the realization of the hopes; if marriage be unadvisable, the tendency to hysteric attacks will often be removed by the change of air, scene, and habits resulting from a distant journey; and a similar course is useful to distract the attention from other consuming cares and passions.

HYTHE, a town and parliamentary borough of Kent, England, on the British channel, 11 m. W. S. W. of Dover; pop. of the municipal borough in 1871, 3,363. It is one of the cinque ports, and was formerly a place of considerable importance; but its harbor has been destroyed by accumulations of matter thrown up by the waves, and it is now a fashionable resort for sea bathing. It has a military school and a theatre. The parliamentary borough includes Folkestone and several smaller places.

I

I, THE 9th letter of the Latin and of most other European alphabets, derived from the 10th Phœnician, Hebrew, &c., where it is named *yod* (Heb. *yad*, hand), and considered

as a consonant. A dot under other consonants denotes its vocality in the Hebrew, and other marks in the other Semitic languages. It is the 11th letter in Armenian, the 28th and last

in Arabic, and the 32d and last in Persian and Turkish. The Greek Ιωτα is the 9th letter, but 10th numeral sign, and is sometimes subscribed to three vowels, thus, α, η, ω . The sound of this letter is the highest in the vocal scale, the counterpart of that of U (oo). This sound (not as pronounced in *mine*, but as in *pique* or *pin*) is symbolic, in many words of all languages, of what is little, thin, slim, swift, shrill, light, flitting; this property is mentioned by Plato. It is uttered through a broad but very thin interstice, which the tongue leaves between itself and the hard palate by being closely raised toward it and pressed against the molar teeth, while the larynx is raised higher than in the formation of any other vocal. Hence it is considered as a palatal by John Wallis, and as a dental by C. Amman. Modern Greeks pronounce $\eta, \epsilon, \alpha, \upsilon, \nu$, and υ like i ; whereas the ancients made $\alpha, \epsilon, \alpha, \upsilon$, and υ diphthongal, giving to the υ a sound like that of the German \ddot{u} , and to the η that of German \ddot{a} . The Romans used I both as a vowel and as a consonant; since they, as well as the Egyptians, Hebrews, and Greeks, knew no such sounds as the French and English give to J (zh and dzh). The Italian language is impaired in its beauty by the frequency of I in its grammatic formations. In Italian it is also used for softening the pronunciation of c, g , and sc . In Spanish manuscripts an initial I is always written Y, for which I is substituted in printing except where it has the consonant sound, as in *yerba*. In English the diphthongal sound in *mine* (Ger. *mein*) is taken for the long sound of I, and its genuine long sound is transferred to E, as in *mete*. The latter sound, long and short, is written in many different ways, some only in single words; as in *be, lee, sea, people, key, caecal, foetus, seize, mien, marine; pin, sieve, forfeit, build, lynx, women, busy, tortoise*. Its English long sound is written in 10 ways, as in *mile, aisle, lie, height, guide, my, ay, eye, buy, rye*. In many words, like *bird, stir*, I has the sound of U in *fur*. The consonantal sound of I is represented by J in Italian and in German and other Teutonic languages, and by Y in French, Spanish, Portuguese, English, &c. (See J, and Y.) It was formerly the practice to class words in I and J together in dictionaries and other alphabetical works; but this is now nearly abandoned in all languages.—In Latin abbreviations, I stands for *invictus, in, inferi, Iulius, Iunius*, &c.; I. C. for *iuris consultus*, &c. During the lethargy of literature I was used to denote 100; but in the Roman numeration it stands for 1. When placed before another numeral it is subtracted, and when following is added; as IV, 4; VI, 6. On French coins it denotes Limoges as the place of coinage.—In music, I is the name of the 9th tie on the neck of the lute and of various old musical instruments. Kirnberger, Fasch, and other organists denoted by it a by-tone between a sharp and b flat.

IAMBlichus, a Neo-Platonic philosopher, born in Chalcis, Cœle-Syria, flourished in the

first half of the 4th century A. D. He was a pupil of Anatolius and Porphyry, and after the death of the latter became the head of the school in Syria. His pupils and contemporaries styled him the "most divine teacher," and declared him the equal of Plato. Little is known of his life, except that he made an excursion annually to the hot springs of Gadara, and that miraculous acts were ascribed to him, which reveal the tendency of the Neo-Platonic school at this time to combine the thaumaturge with the philosopher. He had thoroughly studied the systems of Plato and Pythagoras; and the theology and philosophy of the Chaldeans and Egyptians, and his speculations present a confusion of Hellenic and oriental ideas. The extant books of his work on the Pythagorean philosophy have been published under different titles; the last edition of the 1st (which contains the life of Pythagoras) and 2d is by Kiessling (Leipsic, 1813-'15), of the 3d by Fries (Copenhagen, 1790), of the 4th by Tennulius, &c. (Arnheim, 1668), and of the 7th by Ast (Leipsic, 1817). His work on Egyptian mysteries was published by Thomas Gale (Oxford, 1678). It was translated into English by Taylor the Platonist (Chiswick, 1821), who also translated the "Life of Pythagoras" (London, 1818).

IBARRA, an inland town of Ecuador, capital of the province of Imbabura, 55 m. N. by E. of Quito; pop. about 14,000. It is delightfully situated in the fertile plain of Imbabura, a short distance N. of the volcano of that name. The streets are wide and regular, and many of the houses well built, generally of adobes. The chief buildings are the governor's residence, the parish church in the public square, the hospital, and a beautiful pantheon. There are a college or Latin school and a number of primary and grammar schools in buildings formerly used as convents. Sugar of excellent quality is manufactured; also cotton and woolen stuffs, very fine laces, hats, brandy, cordials or liqueurs, and sweetmeats; and there are extensive salt works. The city was almost totally destroyed by an earthquake in 1868.

IBERIA. I. The ancient Greek name of Spain. The aboriginal Iberi, from whom the name was derived, seem to have occupied the entire peninsula from the strait of Gibraltar to the Pyrenees, until the date of the Carthaginian invasion. They are also said to have occupied southern Gaul as far as the Rhône, where they bordered upon the Ligurians. Ticknor in his "History of Spanish Literature" says: "The Iberians are the oldest of the occupants of the Spanish soil, and the people who, since we can go back no further, must be by us regarded as the original inhabitants of the peninsula. They appear, at the remotest period of which tradition affords us any notice, to have been spread over the whole territory, and to have given to its mountains, rivers, and cities most of the names they still bear; a fierce race, whose power has never been entirely broken by any

of the long line of invaders who at different times have occupied the rest of the country." The Iberians maintained an active commercial intercourse with the Carthaginians, and displayed great activity in mining and much artistic skill in the use of the precious metals. P. A. Boudard has published a work on the Iberian alphabet and language and Iberian coins (4to, with 40 plates, Béziers, 1859). (See **CELTIBERI**, and **BASQUES**.) **II.** The ancient name of the Caucasian country now known as Georgia. This country was bounded by the Caucasus, Albania, Armenia, and Colchis. The Asiatic Iberians were divided into four castes.

IBERIA, a S. parish of Louisiana, intersected by Bayou Teche, and partly occupied by Lake Chetimaches and Vermillion bay; area, about 600 sq. m.; pop. in 1870, 9,042, of whom 4,510 were colored. Part of the parish consists of an island lying between Vermillion and Côte Blanche bays and the gulf of Mexico. The surface is level, and the soil alluvial and fertile. Salt is manufactured. The chief productions in 1870 were 115,843 bushels of Indian corn, 12,414 of sweet potatoes, 1,297 bales of cotton, 12,500 lbs. of rice, 1,854 hogsheads of sugar, and 102,495 gallons of molasses. There were 1,271 horses, 834 mules and asses, 6,543 cattle, 3,511 sheep, and 1,569 swine. Capital, New Iberia.

IBERUS. See **EBRO**.

IBERVILLE, a S. parish of Louisiana, bounded W. by Atchafalaya bayou and S. E. by the Mississippi; area, 450 sq. m.; pop. in 1870, 12,347, of whom 8,675 were colored. It has a flat surface, and is frequently inundated. The lands lying near the rivers are fertile; the rest of the parish is mostly uncultivated. The chief productions in 1870 were 168,645 bushels of Indian corn, 1,178 bales of cotton, 4,907 hogsheads of sugar, and 323,600 gallons of molasses. There were 377 horses, 1,938 mules and asses, 1,602 cattle, 1,483 sheep, and 656 swine. Capital, Plaquemines.

IBERVILLE, a S. W. county of Quebec, Canada, bounded W. by Richelieu river; area, 189 sq. m.; pop. in 1871, 15,413, of whom 13,971 were of French descent. It is traversed by the Vermont Central and the Stanstead, Shefford, and Chambly railroads. Capital, St. Athanase.

IBERVILLE, Pierre le Moyne, sieur d', a Canadian naval and military commander, founder of Louisiana, born in Montreal, July 16, 1661, died in Havana, July 9, 1706. He was one of eleven brothers, most of whom were distinguished in French colonial affairs, three being killed in the service. (See **LE MOYNE**.) Iberville entered the French navy as a midshipman at 14, became captain of a frigate in 1692, and captain of a line-of-battle ship in 1702. In 1686 he served under De Troye in the overland expedition from Canada against the English forts in Hudson bay, was at the taking of Fort Monsipi, and, having with his brother captured two vessels, reduced Fort Quititchon-

en. He was there again in 1688-'9, capturing two English vessels. In 1690 he was one of the leaders in the retaliatory expedition against Schenectady, where he saved the life of John Sanders Glen. In October, 1694, he took Fort Nelson on Hudson bay, losing his brother Châteauguay in the assault. In May, 1696, he was operating on the bay of Fundy with three vessels; he defeated three English ships, capturing the Newport near the mouth of the St. John's, then besieged, took, and demolished Fort Pemaquid, and ravaged Newfoundland, taking almost all the English posts. Proceeding to Hudson bay in 1697, with the Pelican he engaged three English vessels, defeated them, and reduced Fort Bourbon. He was then selected to occupy the mouth of the Mississippi, a point which France had neglected after the death of La Salle. Iberville sailed from Brest with two frigates, Oct. 24, 1698, stopped at Santo Domingo and at Pensacola, which he found occupied by the Spaniards, and on Jan. 31, 1699, anchored at the mouth of the Mobile near Massacre island. He then, with his brother Bienville, Père Anastase Douay, who had been with La Salle on his last voyage, and about 50 men, went in two barges to seek the Mississippi, and on March 2 reached its mouth. He ascended to the Bayagoulas and Oumas, and became assured that he was really on the Mississippi by receiving from the Indians a letter left by Tonty in 1686 for La Salle. Returning to his ships, Iberville built old Fort Biloxi, the first post on the Mississippi, placed Sauvolle in command, and made his brother Bienville king's lieutenant. Early in May, 1699, he sailed for France, but again appeared off Biloxi in the Renommée, Jan. 5, 1700. He then began a new fort on the Mississippi, over which he placed Bienville. He also sent Lesueur with a party to establish a post at the copper mines on the Mankato. He was again in Louisiana in December, 1701, and finding the colony reduced by disease he transferred the settlement to Mobile, beginning the colonization of Alabama. He also occupied Dauphin or Massacre island. His health was seriously undermined by fevers, and he was called away from his Louisiana projects by government. In 1706, with three vessels, he reduced the island of Nevis, and was about to operate on the coast of Carolina, when he was seized with a fatal malady and died in Havana.

IBEX, a species of wild goat, inhabiting the mountainous regions of Switzerland, the Pyrenees, the Caucasus, and Abyssinia. The generic characters are given in the article **GOAT**. The common ibex or steinbock (*capra ibex*, Linn.), the *bouquetin* of the Swiss hunters, is about 5 ft. long and 2½ ft. high at the shoulders; the horns are large, flat, with two longitudinal ridges at the sides and numerous transverse knobs; at first nearly vertical, they curve backward and outward to a length of about 30 in.; they are dark colored and very stout. The color of the adult is brownish, with a gray tint

in winter and reddish in summer; the hair is short and thick; the under parts are whitish, and the dorsal stripe blackish brown. The period of gestation is about 160 days, and the young are usually born in April. They prefer the highest and most inaccessible mountains,

Ibex (*Capra ibex*).

near the line of perpetual snow, and are accordingly hunted with great difficulty and danger. The Abyssinian ibex (*C. jaela*, H. Smith), known to the Greek and Hebrew writers, is rather higher than the preceding species, with longer horns, more circular and less divergent, rounded in front and marked with numerous transverse ridges; the color of the hair is brownish fawn, with a dark dorsal line; under the throat and neck the hair is lengthened. The Caucasian ibex (*C. caucasica*, Guld.) is broader and shorter than the European species; the horns are triangular with distant ridges, very solid, dark brown, and about 28 in. long. The color is dark brown above, head grayish, breast and dorsal line blackish, and throat whitish gray; the hair is coarse, having at the roots a grayish wool. All these animals are remarkable for strength and agility, making immense bounds among the most dangerous precipices; they are said to fall from considerable heights upon the horns, when pressed by the hunter, and apparently receive no injury from the shock. They are all probably more or less mixed with the common wild goat (*C. aegagrus*) of Europe, and have contributed largely to the production of the numerous varieties of the domestic goat. (See GOAT.)

IBICUI, a river of Brazil which rises in the Serra de Santa Anna, province of Rio Grande do Sul, about lat. 31° 20' S. and lon. 54° 30' W., and flows first due N., under the name of Santa Anna, then N. W. and joins the Uruguay between La Cruz and Restoracion, lat. 29° S., after a course of some 400 m. It receives on both sides the waters of numerous tributaries,

VOL. IX.—10

and is navigable for 300 m. by barges and canoes. The upper branch is called Ituzaingo.

IBIS, a wading bird of the family *tantalidae*, including the genera *ibis* (Moehr.) and *geronticus* (Wagl.); the genus *tantalus* (Linn.) will be noticed under Wood IBIS. The genus *ibis* is characterized by a lengthened, slender bill, curved for its whole length, with the sides compressed and tip obtuse; the nostrils are in a groove which extends to the tip of the upper mandible; forehead and base of bill, to behind the eyes and on the chin, in most species bare; wings long and pointed, the first and second quills equal and longest; tail rather short and nearly even; tibia bare for half its length, covered with hexagonal scales; tarsi slender, longer than the middle toe, with broad transverse scales in front; toes long and slender, the lateral ones united to the middle by a small web; hind toe long and slender, claws curved and rather weak. There are about half a dozen species, of which three are found in the United States. The red or scarlet ibis (*I. rubra*, Linn.) is about 28 in. long, the extent of wings a little over 3 ft., and the bill 6½ in. The color is a uniform bright scarlet, with the tips of the outer primaries black; in the young the color is ashy, darkest above, with the under parts and rump white. Its natural habitat is South America and the West Indies, but it has been seen in the southern states by Audubon; it is sometimes called, from the length and shape of the

Scarlet Ibis (*Ibis rubra*).

bill, the pink curlew. The white ibis, Spanish or white curlew (*I. alba*, Linn.), is 25 in. long, with an extent of wings of 40 in., and the bill 7 in. The color of the plumage is pure white, with the tips of the outer five primaries shining greenish black; the bill is red, entirely so in the young birds, but with the terminal half black in the adult; the head in front of the eye is bare; the young birds are of a dull brown color, with the under parts and rump white. This species is very common in the southern Atlantic and gulf states, occasionally straggling as

far north as New Jersey. They breed in large companies on the Florida keys on trees; the nest is about 15 in. in diameter, formed of twigs and roots, flat on the inside; the eggs are three, and are laid only once a year, $2\frac{1}{2}$ by $1\frac{3}{8}$ in., dull white, with pale yellow blotches and reddish brown spots; incubation generally takes place between the 10th of April and the 10th of May; the eggs afford excellent eating, though the yolk is of a reddish orange color when boiled, and the white a liver-colored jelly. When breeding, they fly in flocks of several hundreds to the mud flats, sometimes to great distances, where they feed on crabs, crawfish, and other crustaceans, mollusks, and aquatic animals, until the tide begins to come in, whether by day or night. The flight is rapid and well sustained, effected by alternate flappings and sailings; they often rise very high, performing beautiful evolutions. They are fond of resorting to ponds or lakes in the woods, and often breed in such localities more than 300 m. from the sea; though not taking naturally to the water, they can swim tolerably well when forced to it; the walk is light and graceful. The flesh has a very fishy taste, and is rarely eaten except by the Indians. The glossy ibis (*I. Ordi*, Bonap.) is a smaller species, being about 21 in. long, with a bill of $4\frac{1}{2}$ in.; the general color is chestnut brown, with the back and top of head metallic green glossed with purple; the feathers continue almost to the bill, which is of a dusky black color. It exists in great numbers in Mexico, and it has been procured as far north as Massachusetts. The green ibis (*I. falcinellus*, Linn.) is a native of southern Europe and northern Africa; it much resembles the glossy ibis, being purplish brown, with a deep green mantle; in the young birds the head and neck are pointed with whitish. These ibises all live in warm climates, performing their annual migrations, and are generally seen on lands recently inundated, and on river banks, seeking for worms, snails, crustaceans, insects, and the roots of bulbous plants, or on the sea coast as above mentioned.—The genus *geronticus* has a stronger bill, a longer and broader tail (the third and fourth quills the longest), the tarsi and toes stouter, and the head and neck more denuded of feathers than in the preceding genus; in some of the species the scapulars are long, and consist of decomposed plumes. There are about 20 species, found in the warmer parts of Africa, Asia, and South America, of which only one will be mentioned here, the sacred ibis of the ancient Egyptians (*G. Æthiopicus*, Lath.). It is about as large as a domestic fowl; the plumage is white, with the ends of the quills, the elongated barbs of some of the wing coverts extending over the wings and tail, bill, feet, and naked part of the head and neck, black; it is found throughout northern Africa. This bird was reared in the temples of ancient Egypt with the greatest care, and was embalmed; it was forbidden to kill one on pain of death. This superstitious people revered

the ibis, not because they supposed that it destroyed noxious reptiles, or that there was any relation between the changes of its plumage and the phases of the moon, but because they associated its annual appearance with the period of the inundation of the Nile, the source

Sacred Ibis (*Geronticus Æthiopicus*).

of the fertility and healthfulness of the land; the crafty priests led the people to believe that the increase of the river, which brought the birds there in search of food, was the consequence instead of the cause of their visit; the educated class regarded the ibis as the harbinger of the fruitful epoch of their year, as we look upon the coming of the bluebird and the swallow as the signs of spring. A black ibis was also honored and embalmed. The flight of these birds is powerful and high, with the neck and feet extended horizontally, and accompanied by occasional harsh cries. They probe the mud with their bills in search of insects, worms, mollusks, &c., advancing by slow steps; they arrive in Egypt when the Nile begins to increase, and migrate about the end of June, not nesting in that country; they are caught in great numbers by the modern Egyptians in nets, and their bodies are frequently exposed for sale in the markets. Both species usually go in small flocks. All the species have the same habits, frequenting both overflowed lands and dry open plains; they sometimes devour frogs and small aquatic lizards, but do not destroy serpents as Herodotus and many writers since have maintained; when satiated with food they perch on high trees, and are very watchful; the nest is either on a decayed tree or on the ground, and the eggs are two or three in number. For full details on the sacred ibis, see Savigny's *Histoire naturelle de l'ibis* (8vo, Paris, 1805).

IBN BATUTA. See **BATUTA.**

IBRAHIM PASHA, an Egyptian viceroy, the son, or according to some the adopted son, of

Mehemet Ali, born at Kavala, a village of Roumelia, in 1789, died in Cairo, Nov. 9, 1848. His youth, from his 16th year, was spent in command of the troops in Upper Egypt, and in fighting the wild tribes of that region. In 1812 he reduced by famine the fortress of Ibrim in Nubia, the refuge of the last remnants of the Mamelukes. In September, 1816, he invaded Arabia at the head of the third army sent to reduce the Wahabees, and displayed equal skill, courage, perseverance, and cruelty in organizing his heterogeneous forces, and creating victory out of defeat. After taking many strongholds, he laid siege to the Wahabee capital, which he compelled to surrender. He returned to Cairo in 1819, and, under the guidance of a French officer, created an army disciplined and equipped after the European fashion. In August, 1824, he set sail with a formidable fleet and 17,000 troops for Greece, to aid in suppressing the insurrection there. His army gained many successes, and devastated the Peloponnesus with great cruelty. The European powers intervened, and his fleet was destroyed at Navarino, Oct. 20, 1827, by the combined squadrons of Russia, France, and England; and in 1828 he was recalled to Egypt by the peremptory order of Mehemet Ali. There again he busied himself in organizing an army, and in creating, with the aid of French engineers, a fleet superior to that which he had lost at Navarino. Both were ready in 1831, when the disobedience of the pasha of Acre furnished Mehemet Ali the desired opportunity of invading Syria. Ibrahim, to whom the expedition was intrusted, lost 5,000 men by cholera before he could leave Egypt. On Nov. 29 he laid siege to Acre, having terrified into surrender Gaza, Jaffa, and Kaiffa. A Turkish army came to the relief of Acre, and was surprised and routed by Ibrahim near Tripoli, and on May 27, 1832, he carried Acre by storm. He pushed on immediately for Aleppo. Damascus opened its gates to him. The Turks were again defeated at Homs, and afterward at Hamah, and finally the fall of Aleppo left him master of Syria. Pursuing the Turks, he overtook and routed them at Adana. Meanwhile his fleet had driven that of the Turks to seek refuge beneath the forts of Constantinople. Having obtained another brilliant victory at Ulu Kislak, he marched to Konieh, where on Dec. 20 he found himself confronting 60,000 Turks commanded by Reshid Pasha. Though the Egyptians were not half as numerous, they routed the Turks completely, and the grand vizier himself was taken prisoner with immense booty. His father's commands obliged him to wait for reinforcements, instead of marching on Constantinople. This delay enabled the sultan to invoke the aid of the czar; and on Feb. 20, 1833, a Russian fleet cast anchor in the Bosphorus. The western powers interfered, and a peace was concluded, leaving to Mehemet Ali the government of Syria and the pashalic of Adana. Ibrahim governed these

provinces with firmness, repressed disorders, and encouraged agriculture, industry, and commerce. The resentment of the sultan led in 1839 to a renewal of hostilities, which resulted in another crushing defeat by Ibrahim of the Turkish forces, at Nizib, on June 24. Here again, obedient to his father's order, and in compliance with the request of the French government, he stopped short in his course of victory. A treaty concluded July 15, 1840, between the Porte and the western powers (without the knowledge of France), stipulated that Mehemet Ali should either consent to limit his authority to Palestine, or be compelled to do so by the united forces of England and Austria. An insurrection broke out among the mountain tribes of the Lebanon and spread rapidly on every side. Beyrout, after a bombardment of nine days, was evacuated by the Egyptian garrison, Sidon yielded without resistance, St. Jean d'Acre surrendered after three hours' fire; the whole coast of Syria was in possession of the English, and Commodore Napier, anchoring in the bay of Alexandria, sent an ultimatum which Mehemet Ali accepted. Ibrahim, who had fallen back to Damascus, and found his position extremely difficult, was now commanded to evacuate Syria. This retreat, conducted with consummate ability, but with great losses, closed his military career. Thereafter he devoted his whole time to the culture of his immense estates on the plain of Heliopolis, until he was placed in charge of the government on the retirement of his father in 1844. His own infirmities, however, compelled him to seek a more temperate climate and the medical skill of western Europe. Returning to Egypt, he began several reforms suggested by what he had observed during his travels; but a violent attack of dysentery again forced him to a change of climate, and he spent the winter of 1847-'8 in Italy. He went to Constantinople in July, 1848, where he was confirmed in his rank of viceroys.

IBRAILA. See BRAILA.

IBYCUS, a Greek lyric poet who lived in the middle of the 6th century B. C. He was a native of Rhegium in Italy, and lived at the court of Polycrates, tyrant of Samos. It is narrated that while travelling near Corinth he was mortally wounded by robbers, and invoked a flock of cranes, then passing overhead, to avenge his death. The cranes directed their flight to Corinth, and hovered over the people in the theatre. The murderers were present, and one of them on seeing the cranes exclaimed involuntarily, "Behold the avengers of Ibycus." This led to an inquiry, and to the punishment of the assassins. The poetry of Ibycus was mostly erotic, but sometimes mythical and heroic. But a few fragments of his works are in existence, the best edition of which is that of Schneidewin (Göttingen, 1835).

ICA, an inland town of Peru, capital of a district of the same name, in the department and 170 m. S. S. E. of the city of Lima; pop. about

7,000. It is situated in a sandy plain, and the heat is excessive; nevertheless, Ica exports immense quantities of wheat and other grains, exquisite olive oil, and superior wines and brandies, through its port, Pisco, 48 m. N. N. W., to which place a railway has been in operation since 1872. The cost of the line was \$1,364,062 50. An extensive trade is also carried on in fish taken on the Pacific coast. There are several schools, which are well attended. In the adjacent district are found species of stones called *dentritis*, which when polished present curious views of trees, plants, edifices, &c.

ICARUS. See *DÆDALUS*.

ICE, water or other fluid solidified by freezing. Various liquids become partially solid at low temperatures, but this is commonly owing to the water of which they are in part composed; and none of them produce a clear uniform solid like that of frozen water. At 32° F. under ordinary circumstances water begins to crystallize. Slender prisms, usually of six sides, and terminated by six-sided pyramids, form in it, and arrange themselves in lines crossing each other at angles of 60° and 120°. The presence of salts in solution impedes this process, and when at last it takes place at a temperature below 32°, the greater portion of the foreign matter is excluded from the ice, which consequently is nearer the composition of pure water. Advantage is taken of this in some operations designed to concentrate the strength of liquors, as of vinegar, the portion that first crystallizes by cold being removed, and leaving the residue less diluted. Pure water contained in a polished vessel and kept perfectly quiet may be reduced to several degrees below the freezing point without freezing; but agitation or the introduction of foreign bodies will cause congelation to take place suddenly, and as the ice is formed latent heat is liberated, and the temperature rises to 32°. Saline solutions sometimes exhibit a similar reluctance to deposit their salts in crystalline form even when reduced by evaporation below their point of saturation; and in these cases crystallization is often suddenly induced by the same methods that cause the water to congeal. From about 39° water expands as its temperature is reduced, with the exertion of prodigious force. A hollow globe of brass with a cavity only an inch in diameter, filled with water, has been burst by the freezing of this, exerting a force, as estimated, of 27,720 lbs. The effect of this property is seen in the tendency of ice to plough up the banks of ponds, to split off masses of rock from mountain cliffs, and to loosen and pulverize the soil through which it is diffused. The effect last named is not perceived till the thaws of spring, when the frost is said to come out of the ground. This force has been artificially applied to splitting rocks and trunks of trees by allowing water to freeze in their fissures. This expansion, estimated by Boyle at one ninth the original volume, gives to ice less density than that

of water, so that it floats. Its specific gravity by this estimate should be 0.9; M. Brunner in his series of experiments found it to vary from 0.918 at 0° C. to 0.92025 at —20° C. But for this exception, which is however not a singular one, to the usual law of increase of density by reduction of temperature, ice as it forms would sink to the bottom, and there accumulate beyond the reach of atmospheric heat; great collections of water would be chilled throughout, and their fitness for sustaining life in cold regions be entirely destroyed. But as the ice, a bad conductor of heat, covers the water, it serves as a protecting sheet to retain the warmth below, and preserve the water from the extreme temperature that prevails above. As the cold increases, the solid ice is found to be subject to the usual law, contracting as found by Brunner more than other solids; and upon ponds in excessively cold weather it contracts, and in shrinking parts asunder in the weakest places with loud reports. A form of ice called anchor ice is often seen in cold weather attached to objects at the bottom of streams. Its character is explained by Prof. Dewey on the supposition that the whole body of water is cooled below the freezing point, but under conditions of quietness opposed to the formation of ice. The substances at the bottom serve as points of congelation, like those introduced into saline solutions to cause crystallization to take place, and ice forms upon them. It is observed to gather in a clear cold night, when the surface of the water is not frozen, and its temperature is at the freezing point, that of the air being still lower. The layers of ice are sometimes 3 in. thick; and as soon as they are detached from the bodies which hold them down they rise to the surface. In some of the crevasses of the Alpine glaciers immense icicles from 20 to 30 ft. long were found by Tyndall, hanging from the coping of snow which lines the edges of the chasms. Near the poles, and on mountains at a certain height in all latitudes, there are immense masses of what may be considered permanent ice; and there are said to be places in Siberia, even where there is a limited culture of the ground, where ice is always found at a certain depth below the surface. In a well which was sunk at Yakutsk the earth was found firmly frozen to the depth of 382 ft., some of the strata being entirely of ice. From the exposed polar ice fields and glaciers great masses become detached and form icebergs. (See *ICEBERGS*.)—The regelation of ice, a phenomenon first distinctly observed by Faraday, has recently attracted much attention, especially in regard to a controversy on the subject of glaciers. Regelation takes place between blocks of ice where they are strongly pressed together, even in warm water, and in cold water it will take place when the masses only touch each other. When fragments of ice are subjected to pressure in a mould, they may be formed into a solid block. When but little

pressure is used, it is necessary that the ice should be but little below the freezing point. This is the explanation of snow-ball making. As the freezing point of water is lowered by pressure, it is easy to understand how this formation of solid blocks from fragments may take place. A certain degree of viscosity, approaching liquefaction, is produced, by which the particles are reunited, and are firmly held as soon as the pressure is removed or lessened. The motions of glaciers, attended as they are by alterations in the form of immense masses of ice, is explained by this property that ice has of liquefying under enormous pressure. Mountains of ice squeezed into crevasses must exert a force which we probably cannot produce by any artificial means, and as a consequence the ice may be made viscous when at a temperature considerably below the freezing point. For other properties of ice, see **GLACIER, SNOW, and FREEZING, ARTIFICIAL.**—**ICE TRADE.** Ice was little known as an article of commerce until the early part of the present century. In the 17th century its use was so common in France that many dealt in it and in snow, gathering these in winter and packing them closely in pits surrounded with straw or other non-conducting substances and protected from the air. The Italian peasants also have long found a profitable business in collecting the snow upon the Apennines and storing it in the caves of these mountains to supply the large demand at Naples. The bodies of ice found in the recesses of Mount Etna, and excavated sometimes from beneath beds of lava which have flowed over them, are noticed in the article **ETNA**. In the last century the gathering and storing of ice for summer use is known to have been practised in some of the middle states of the American Union, the receptacles for preserving it being deep cellars, placed so as to be readily drained, or from which the water was pumped out as it collected; but though most wanted in countries where it is not naturally produced, no attempts had been made to transport it by sea. This was first done by Mr. Frederick Tudor of Boston, who sailed with a cargo of 130 tons in his own brig to Martinique in 1805. He persevered in the business, though making little or no profit, till after the close of the war of 1812. In 1815 he obtained the monopoly of the Havana business and important privileges from the Cuban government. In 1817 he introduced the trade into Charleston, S. C., the next year into Savannah, and in 1820 into New Orleans. Frequent disasters attended his enterprises, and in 1832 his entire shipments amounted to only 4,352 tons, the whole of which came from Fresh pond in Cambridge. In May, 1833, he sent the first cargo of ice to the East Indies, which was delivered at Calcutta in the autumn of that year. Of 180 tons, one third was wasted on the voyage, and 20 tons more in going up the Ganges. It was packed in large blocks closely fitted together between a double plank

casing filled with dry tan. The ice was sold immediately at half the cost of that prepared by the natives. At the present time a waste of about one half is generally expected on this voyage. In 1834 the first cargo was shipped by Mr. Tudor to Brazil. Until 1836 he conducted the whole trade; but as it became profitable others began to enter into it, and from other ports besides Boston. That port, however, still has the great bulk of the trade, the shipments having been as follows, according to the incomplete returns that have been preserved:

In 1805.....	130 tons.	In 1866.....	124,751 tons.
" 1816.....	1,200 "	" 1868.....	105,818 "
" 1826.....	4,000 "	" 1870.....	78,808 "
" 1836.....	12,000 "	" 1871.....	109,298 "
" 1846.....	65,000 "	" 1872.....	98,859 "
" 1856.....	146,000 "	" 1873.....	81,266 "

Of the amount shipped in 1873, 30,333 tons went to coastwise and 50,933 tons to foreign ports. The total exports from the United States to foreign ports for the year ending June 30, 1873, were 53,553 tons, valued at \$188,095, of which 48,890 tons, valued at \$175,848, were from Boston; 14,449 tons were shipped to Cuba, 13,342 to the East Indies, 10,186 to the British West Indies and British Honduras, 4,392 to British Guiana, and the rest to other portions of the West Indies, South America, &c. Into the interior ice has been carried by railroad in considerable quantity as far as Knoxville, Tenn. Some ice was formerly shipped to England, but the British market is now entirely supplied from Norway, the Norwegian ice being cheaper than the American, though of inferior quality. The imports into the United Kingdom in 1872 amounted to 139,421 tons, valued at £128,251. The chief difficulty in establishing the ice business in warm countries has been the necessity of constructing houses especially adapted for preserving the ice; and these to be profitable must be upon a large scale. One of these erected in 1845 at Calcutta, by Mr. Wyeth of Cambridge, covered more than three fourths of an acre, and was capable of holding 30,000 tons of ice. Its walls of brick were triple, with flues or air spaces between; their length was 198 by 178 ft., and their height 40 ft. The building was covered by five roofs, and between every two contiguous ones were air spaces.—New York city is supplied with ice chiefly from small lakes near the Hudson river, or from the river itself above Newburgh. The whole amount gathered when the season is favorable is about 1,160,000 tons, of which 200,000 tons are from the lakes (Rockland lake in Orange co. supplying 80,000 tons), and the rest from the river. Deducting one third for wastage, we have 774,000 tons, the amount required to supply the present demand of New York and Brooklyn. The demand increases at the rate of about 70,000 tons a year. With the growth of the business upon the coast it has also spread in the interior, where, especially near the large towns, the gathering of ice is now an important business. The great

lakes furnish supplies which are carried by railroad to the cities lying south, and through the Illinois river ice is sent down the Mississippi. In the autumn the ice boats come up to the vicinity of Peru, Ill., where they are allowed to be frozen in. In the winter they are filled, and in the spring when the ice breaks up they float down with their freight. The ice produced in deep ponds by the severe cold weather of New England is particularly adapted by its hardness and compactness to keep well, while the purity of the water gives it clearness and renders it especially agreeable. The ice obtained from the Kennebec river is most celebrated. That formed upon the shallow waters of Great Britain is found to be porous and very inferior in durability to that from the United States of the same thickness. —The methods of gathering and storing ice are entirely American. When the ice is 9 in. to a foot thick, or if for exportation 20 in. thick, the snow, if there be any, is cleared off the surface with wooden scrapers, each drawn by one horse. Another scraper armed with a steel blade planes off the porous upper layer to the depth of 3 in. or more if necessary. The surface is then marked off in large squares by a sort of plough drawn by a horse, which cuts a groove about 3 in. deep. A machine somewhat like a harrow, with three or more parallel rows of teeth, which may be 22 in. apart, is next drawn along the lines already made, one row of teeth running in the grooves as a guide; and as many more cuts are made as there are more rows of teeth. This is repeated upon the cross lines, and the whole area is thus cut into small squares. If necessary, a deeper plough is afterward run through all the grooves to increase their depth. A row of blocks is then sawn out by hand, and being taken out or thrust under the others, room is made for splitting off the adjoining squares, which is done by an ice spade dropped into the grooves. In very cold weather the ice yields readily to a slight wedging force. The blocks are sometimes floated through the canals opened in the ice to the shore, where they are hoisted out; and they are also sometimes jerked with a hook at the end of a pole up a slide upon a platform placed at the edge of the opening, and from this platform they are slid along on the sleds which convey them away. At the ice houses the blocks are raised often by steam power up an inclined plane to the top of the building, and thence let down another plane to any part within where it is required for packing. The storehouses, huge wooden buildings without windows standing around the edges of the ponds or along the banks of the rivers, present a very singular appearance. They are from 100 to 200 ft. long and very broad, with a capacity sometimes exceeding 20,000 tons. One at Athens on the Hudson holds 58,000 tons, and two at Rockland lake in Orange co., N. Y., hold 40,000 tons each. Around Fresh pond at Cambridge, Mass., there is a

large number of these buildings. Between their walls they are filled in with saw dust. As the season of the ice harvest is short and uncertain, the gathering of the crop is conducted with the greatest activity at favorable times.

ICEBERGS, and **Ice Islands**, floating masses of ice gathered on the coast of polar regions, and set adrift by force of winds and currents. Many icebergs are produced from glaciers, which, thrust down from the elevated snowy lands in the interior, are moved onward into the deep waters, where the fragments broken off from the advance border are floated away. The edges of glaciers extending many miles along a precipitous coast have been seen to fall with terrific violence into the sea beneath, and at once be transformed into floating islands of ice. These carry with them the masses of rock gathered up by the ice in its progress as a glacier, and transport them to new localities in warmer latitudes. (See **DILUVIUM**, and **GLACIER**.) Ice islands of vast extent are also produced by the breaking up of the great fields of sea-made ice which accumulate along the shores of the frigid waters. In 1817 the ice covering several thousand square miles of the sea N. of Iceland, and chiefly on the E. coast of Greenland, most of which, it is believed, had not been moved for nearly 400 years, was suddenly broken up and dispersed over the waters of the North Atlantic. Portions of it were carried far to the eastward of the usual range of icebergs from the north, and approached within 800 m. of Ireland, or to lon. 32° W. The breaking up of this ice led to the expedition of Capt. Ross, the second of the present century in search of a northwest passage, the opinion prevailing that the climate had essentially changed, and that the northern seas would continue open. The drift of the northern icebergs is with the great polar currents, one of which sets in a S. S. W. direction between Iceland and Greenland, and another along the W. side of Baffin bay, meeting the former near the coast of Labrador. They are brought against the American continent and the W. shores of its bays in consequence of not catching at once the more rapid rotating motion of the earth as they pass upon larger parallels, and so allowing this to slip from under them. The greatest numbers are produced on the W. side of Greenland; and, as observed by Dr. Kane, "perhaps the most remarkable place for the genesis of icebergs on the face of the globe" is at Jacob's bight, an inlet a little N. of Disco island, in about lat. 71° and lon. 56°. From Labrador the ice is floated with the current past Newfoundland, and meeting near the Great Bank the warming influences of the Gulf stream, it usually disappears about lat. 42°. The extreme limit is in lat. 40°. Sometimes the ice is carried as far to the eastward as the Azores. In the southern hemisphere icebergs drift still nearer to the equator, being occasionally seen off the cape of Good Hope. As they reach their southern limit in the north-

ern hemisphere their influence is felt in sensibly cooling the waters of the Gulf stream for 40 to 50 m. around, and on approaching them the thermometer has been known to fall 17° or 18°. When driven, as they sometimes are, in large numbers into Hudson bay, they diffuse intense cold over the northern portion of the continent. The floating masses assume a variety of forms. Some spread out into sheets, which cover hundreds of square miles and rise only a few feet above the water. These are called fields, or, when their whole area can be defined from the mast head, floes. A number of sheets succeeding each other in one direction constitute a stream, or lying together in great collections, a pack. The surface of the sheets is often diversified by projections above the general level, which are called hummocks; they are forced up by the floes pressing against each other, and are sometimes in the form of great slabs supported by one edge. Dr. Kane noticed that these become bent by their own weight, even when the thermometer continues far below the freezing point. The most solid clear ice exhibits this yielding property of its particles. The surface of the ice fields is usually covered with snow, and when the ice is no more than 2 ft. thick it gives no trace of salt on the surface. The thicker ice contains open pools of fresh water. The bergs are real floating mountains of ice, rugged and picturesque, with peaks jutting high into the air, and strange forms in the glittering hard blue ice, which one easily converts into imaginary castles and grotesque architectural designs. They are occasionally seen in great numbers moving on together. Dr. Kane in his first cruise counted 280 in sight at one time, most of which exceeded 250 ft. in height, and some even exceeded 300 ft. The dimensions of the largest are measured by miles. Lieut. Parry in the first expedition of Ross encountered one in Baffin bay, 7 leagues from land, the length of which was 4,169 yards, its breadth 3,869, and its height 51 ft. It was aground in 61 fathoms. Its cliffs recalled those of the chalk on the coast of England W. of Dover. Dr. Kane saw one aground in soundings of 520 ft. which with every change of tide swung round upon its axis; and Capt. Ross describes several he saw aground together in Baffin bay in water 1,500 ft. deep. The officers of the French exploring expedition in the Southern ocean measured several bergs from 2 to 5 m. each in length, and from 100 to 225 ft. high. Capt. Dumont d'Urville reports one in the Southern ocean 13 m. long, with vertical walls 100 ft. high. The portion of these masses of ice seen above the water is only about an eighth part of their entire bulk. Such bodies, weighing hundreds of millions of tons, moved on by a broad current of water, exert a power against obstacles of which we can form little idea. In their action upon the bottom of the sea, as explained in the article *DILUVIUM*, many geologists recognize a repetition of the phenomena

accompanying the distribution of the drift formation, and the production of its sands and gravel and rounded bowlders. Dr. Kane remarks of the display of power exhibited by the movements of these huge bodies as follows: "Nothing can be more imposing than the rotation of a berg. I have often watched one, rocking its earth-stained sides in steadily deepening curves, as if to gather energy for some desperate gymnastic feat; and then turning itself slowly over in a monster somerset, and vibrating as its head rose into the new element, like a leviathan shaking the water from its crest. It was impossible not to have suggestions thrust upon me of their agency in modifying the geological disposition of the earth's surface."—Icebergs occur in great numbers in the North Atlantic in the latter part of the summer, and form the chief danger which then besets the navigation between Europe and North America. These mountains and fields of ice, however, have sometimes served as a means of safety to persons who have taken refuge on them, or floated off with them accidentally. Several members of Hall's exploring expedition were in 1872 rescued from a floe on which they had drifted 196 days and a distance of 2,000 miles. (See *ARCTIC DISCOVERY*.)

ICELAND, a large island in the North Atlantic ocean, subject to the Danish crown, geographically belonging to the western hemisphere, about 160 m. E. of Greenland, 600 m. W. of Norway, 500 m. N. W. of the Shetlands, and 250 m. N. W. of the Faroe islands. It is situated between lat. 63° 24' and 66° 33' N., and lon. 13° 31' and 24° 17' W.; greatest length 325 m., greatest breadth 200 m.; area, including adjacent islands, 39,758 sq. m., of which 16,243 are habitable. The population of Iceland in its most flourishing period exceeded 100,000; recent censuses give it as follows: 1864, 68,084; 1869, 69,506; 1870, 69,763. Reykiavik, the capital, has a population of about 1,400. In shape Iceland somewhat resembles a heart with its apex to the south. The coast line on the south is but little broken, several of its openings having been filled up during eruptions of the neighboring volcanoes; but in all other directions it is deeply indented with bays, fiords, and jutting promontories. The fiords extend far inland between lofty mountains, whose sides are carved into gigantic terraces. The principal of these is Isafiord in the N. W. peninsula. The western fiords are studded with rocky islets, and open, like those of the north and northeast, to enormous ice drifts. The chief islands on the coast are the Vestmanna isles in the south, which form a county by themselves. The best harbors are those of Reykiavik, in a bight of Faxafiord, in the southwest, Hafnarfiord in the west, Akureyri on the Eyjafiord in the north, and Vopnafiord in the east.—Iceland is apparently of volcanic origin; its surface in the interior is composed of an elevated band of palagonite tufa pierced by trachyte, and having basalt on either

side. This basalt, the oldest formation, underlies the other two, the palagonite, which is next in age, and the lava, comprising all the strata due to recent volcanic action. Although the N. W. peninsula is composed of lofty ridges with here and there an extinct volcano, the chief mountain system is in the south. It forms a triangular mass, with its apex at Thrandar Jökull in the east, and its base extending from Ok in the west to Eyjafjalla in the south. Toward the apex the great Vatna Jökull group covers an area of 3,500 sq. m. with its gigantic glaciers and snow fields. The mountains are distinguished into fells, which are generally free from snow in summer, and jökulls or ice mountains, which are shrouded in perpetual snow. The name of *skál* is given to perfectly symmetrical mountains. The principal jökulls are the Oræfa, 6,405 ft., the eastern Snæfell, 5,958 ft., and the western Snæfell, 4,699 ft. The volcanoes belong to all three classes. Beyond the mountain masses lies the great central table land, from 1,500 to 2,000 ft. above the sea, and forming a wilderness covered with vast lava beds, barren heights or rolling rocky uplands, tracts of black volcanic sand, hillsides and valleys dotted with hot springs and sulfataras, and bottom lands filled with bog and mud. Over this desert three main roads, or rather tracks, connect the settlements near the fiords and the rare low plains and valleys extending inland along the water-courses. The most remarkable and fertile valleys are those clustering around Eyjafjord in the north, that of Lagarfljot in the east, and those of the Hvita and Thjorsa in the south. Volcanic action has manifested itself over a broad belt of country, extending from Cape Reykjanes in the southwest to Krafla in the north. Within this belt are the principal volcanoes, including Hecla. (See HECLA.) From 27 different spots, counting volcanic craters in the sea off Cape Reykjanes, 86 eruptions have occurred since 874, the last being those of Skapta in 1861 and of Trölladyn-gjá in 1862. The lava has been thrown out from grassy plains in the north as well as from the enormous double chasm of Katla in the southern uplands. Of the lava beds, the Odatha Hraun covers 1,160 sq. m., a second extends 73 m. from Skjaldbreith and Klöthufell to Reykjanes, and a third, around Hecla, is 25 m. long and 10 m. broad. Another peculiarity is what is called the *gjá* or rifts in the deep lava beds, which are zigzag rents running from northeast to southwest. The most remarkable are the Almanna-gjá and Hrafna-gjá at Thingvellir, and the rift into which pours the Jökulsa at Dettifoss.—The principal lakes in Iceland are the Myvatn (Midge lake) in the north, much diminished in depth and extent by the lava streams from Krafla in 1724-'30, and Thingvallavatn in the southwest, 10 m. long by 4 wide. There are besides two principal groups of lakes, those of the Arnarvatn (Eagle tarns) dotting a large district N. and W. of Eyriks

Jökull, and Fiskivatn (Fish tarns) at the foot of Skapta, which are the remains of a large lake that existed previous to the eruption of 1783. The larger rivers take their rise in the southern mountains. The Jökulsa, reputed the largest, rises at the foot of Vatna, and flows N. to the Axafjord. About 30 m. from the sea it falls over a perpendicular wall in its lava bed, forming a magnificent waterfall. The Skjal-fandafjot has its source between Vatna and Arnasfell, and flows N. into Skjalfandi bay. The Jökuldalsa and the Lagarfljot flow N. E. from the snow fields of Vatna. The most important rivers in the west and south are the Hvita (or, as it is called near its mouth, the Olfusa), Thjorsa, and Kudafjot. The most celebrated feature of Iceland scenery is the great number of intermittent hot springs, chiefly in the S. W. division, which have given the name of geysers to similar springs elsewhere. (See GEYSERS.)—The climate of Iceland seems to have changed greatly since its first settlement. The ice drifts from Greenland, which formerly visited its shores only every other year, have of late come for 15 years in succession, surrounding two thirds of the island with a compact mass, and remaining from three to five months. When it comes in January or February, it goes away in March or April; then it affects the ensuing vegetation but little, while it brings a welcome supply of whales. If it comes in April or May, it remains until the end of July, stopping vegetation and destroying all the crops. The average winter temperature at Reykjavik, 29·3° F., is higher than at Aberdeen, 26° F.; the average summer temperature is 53·6°, and that of the whole year 39·4°, being about the same as that of Moscow the whole year round. At Akureyri, in the north, the average summer heat is 45·5°, that of winter 20·7°, and the mean for the year is 32°. The difference of climate between the north and south of the island is attributed to the Gulf stream, which sweeps round the S. and S. W. coasts. In the south great quantities of rain fall in winter and summer, and sharp winds are frequent; thunder, except in winter, is very seldom heard. The climate of the north is much more dry and regular.—The lowlands and protected valleys afford excellent pasturage, where the soil contains all the elements of fertility. "The mountains," says Baring-Gould, "are generally destitute of herbage, and the valleys are filled with cold morasses. Grass springs on the slight elevations above the swamps, in the dells, and around the lakes. By drainage a large percentage of marsh might be reclaimed; but some must always remain hopeless bog. The extraordinary amount of swamp is due to the fact that the ground is frozen at the depth of 6 or 8 ft., so that when there is a thaw the valleys are flooded, and the water, unable to drain through, rots the soil." Many bottoms are filled with an amazing depth of rich soil, yet the prevalent ignorance of agricultural methods prevents their being turned to any ad-

vantage. The luxuriant herbage on the sloping sides of the fields consists of several kinds of grasses mingled with the leaves of stunted willow, which is greedily devoured by the sheep, and with dwarf mountain birch. On the marshes grow several kinds of sedge, and the *tún* or home field is overstrewn with the yellow *ranunculus*. Iceland is almost a treeless country; in certain spots are low coppices of birch, the trees being mere shrubs 10 or 12 ft. high, and in one or two protected places only a few mountain ashes about 30 ft. high excite the admiration of the natives. Hay raised in the lowlands is the chief crop; a few patches of oats are occasionally seen in sheltered situations, but even these do not always ripen. No other kind of grain is raised; but a species of wild corn (*elymus arenarius*) growing on the sand flats by the sea affords a much prized harvest; the straw is used for thatching and fodder, and the meal, flavored with cinnamon, is made into very palatable thin cakes. Potatoes, carrots, cabbage, lettuce, spinach, parsley, cresses, and radishes are cultivated in small patches. The only other valuable vegetable production is the Iceland moss of commerce. Agriculture has greatly improved of late years.—Among the wild animals are several kinds of foxes which are hunted for their skins, the blue fox especially. Bears are frequent visitors, borne to the island on the ice drifts from Greenland. Reindeer were imported from Denmark about 1770, and now roam in large herds in the solitudes of the interior; though so valuable for locomotion, their utility is altogether overlooked. The seal breeds everywhere on the coast and its numerous islands; the whale is also seen, sometimes in flocks, in the fiords and bays, as well as a shark indigenous to these waters (*scygnus microcephalus*). The cod, herring, haddock, halibut, trout, salmon, and eels abound in the fiords and the fresh-water lakes and rivers. Shell fish, the mussel especially, are present in enormous quantities. There are in Iceland 7 families and 34 species of mammals, of which 24 live in the water, and 13 varieties of cetacea. Birds swarm everywhere; among the indigenous ones are the Iceland falcon, ptarmigan, goldeneye, harlequin duck, and northern wren. The eider duck is jealously protected by the inhabitants. There are 6 families and about 90 species of birds, of which 54 are water fowl. No reptiles have ever been discovered. Of fish, which are as yet but little known, Faber mentions 49 varieties, of which 7 are fresh-water fish. Domestic animals constitute the great wealth of the Icelanders; these are cows, horses, and sheep, and goats in the north. In 1870 there were in the island 352,443 sheep, 30,078 horses, and 18,189 cattle. The early colonists introduced geese and swine; but the geese are now all wild, and the hog has disappeared. The dog is of the Esquimaux type, and of great use to the farmer.—Mineral deposits, showing the presence of copper, iron,

lead, and silver, are found in many places; but, from their poorness and the absence of fuel, no attempt has been made to work them. Plumbago was discovered near Krafla by Baring-Gould, and magnetic iron abounds among the volcanic rocks. The chief sulphur deposits are at the vapor springs of Hengill near Thingvalla lake, at Krisuvik, and in the neighborhood of Myvatn. In the latter region is "Obsidian mountain," a ridge in many places composed of pure obsidian, which might be a source of public wealth. There are feldspar, chalcidones, zeolites, amethysts, topaz, opal, porphyry, and malachite. One of the most singular formations of Iceland is a kind of brown coal called *surturbrandr*, which lies in beds between clinkstone and trap; it consists partly of carbonized stems of trees, partly of a more coherent layer of coal mixed with schist, and is of no importance as a source of national wealth.—The modern Icelanders are the descendants of the Norwegians who settled in that country in 874 and the following years; a few colonists from Ireland and Scotland had also settled in the country previous to the Norwegian discovery, or came thither afterward. The language spoken by all is the purest Norse. The men are tall, fair-complexioned, and blue-eyed, with frames hardened by constant exposure to the weather. Recent travellers complain of their tendency to idleness and intemperance; but they are strictly upright, truthful, generous, and hospitable. The women are industrious and chaste. Religious faith and the domestic virtues are traditional in every household. Education is universal; it is almost impossible to find an adult unable to read and write. The settlements are chiefly scattered along the coast, and in certain sheltered valleys and lowlands, the most populous district being in the neighborhood of Skagaford in the north. Social as well as commercial intercourse is extremely limited. There is nothing in the whole island that can be called a road; no vehicle of any kind is used on land; locomotion both for man and merchandise is only practicable on horseback and at certain seasons. A very few houses are of stone, a few of wood, but the greater number are partly of turf and partly of lava blocks pointed with moss and thatched with sod. Coal is only to be had in the towns; elsewhere the only fuel consists of sheep dung mixed with fish bones. No fire is made save in the small kitchen even in winter, and that only to prepare food, the other rooms in the farm house remaining damp and foul. In the Vestmanna islands and in many places on the mainland, portions of the sea parrot and petrel are dried, mixed with manure, and used for fuel. The main staple of food is stock fish, which is eaten with sour butter. The only meat is mutton, which is boiled, then pressed dry, cut into lumps, and laid by without salt; sometimes it is also stewed in milk. The first necessities of life are imported. The least mortality (128)

is in February, the coldest month, and the highest (205) in July, the warmest. Cutaneous diseases, occasioned by want of cleanliness and proper nourishment, are most prevalent; diarrhoea is frequent in spring; typhus and small-pox have often swept away multitudes; leprosy is not uncommon, especially on the islands, where it takes the form of elephantiasis. Consumption is unknown, owing probably to the purity of the air and its being charged with ozone.—There are no manufactures of any kind, only the simplest articles of consumption being woven in the homestead. Several of these, such as guernseys and mittens, are exported. The commerce of Iceland had been quite flourishing during the period of its independence; active commercial relations were kept up with Norway, England, and Germany till the union of Norway with Denmark in 1387, when the Danish crown began usurping a complete monopoly, and finally (in 1602) farmed out the trade with Iceland to a Copenhagen company. This monopoly was abolished in 1853, and at present the only restriction to free intercourse is the taking out a trade license amounting to about 50 cents per ton of the ship's burden. Foreigners enjoy the same rights of residence, holding property, and trading, which belong to the natives. The fisheries of Iceland, if carried on with a proper degree of intelligence, would prove an exhaustless source of wealth; but only 10 per cent. of the population are fishermen, and the methods used are inefficient. Along the coast are 34 authorized trading posts, of which only 27 are used; of these, 6 are in the south, 11 in the west, and 10 in the north-east; 62 merchants reside in these, 26 being Icelanders, the others Danes or representatives of Danish houses. There are no banks. The trade is by barter; the Icelander is entirely in the merchant's power and must accept his prices. Attempts to break up this monopoly have recently been made by a Norwegian company of Bergen, which has an establishment at Reykiavik, and branches in Hafnarfiord and other places. There is but one native ship in the foreign trade. In 1869 the number of foreign vessels which visited the trading stations was 99 from Denmark, with a tonnage of 9,358, and 50 from other countries, with a tonnage of 4,555. The principal imports are cereals, wheat bread, coffee, sugar, spirits, snuff, and tobacco. A decrease is perceptible of late in the quantity of brandy imported, although even now it amounts to 24 quarts annually for every adult male, besides rum, punch extracts, and other spirituous drinks. The principal exports are fish, both salted and dried, salt roe, liver oil, salt meat, tallow, sheepskins, wool, guernseys, stockings, mittens, coarse woollen stuff called *vadmel*, eider down, feathers, and horses; the whole valued for 1869 at about \$700,000. Formerly considerable quantities of sulphur were exported; but owing to the absence of fuel and the inaccessibility of the mines, as well as the want of remunerative demand,

they have not been worked for many years. An Englishman has lately obtained a 50 years' lease of the sulphur mines near Myvatn, which may acquire commercial importance when those of Sicily are exhausted.—There are but few primary schools in the island, but parents, besides teaching their children all they know themselves, are careful to send them for further instruction to better informed neighbors. All the books and manuscripts in the house, as well as those to be found within a radius of 50 miles, are read aloud over and over again to the family and discussed by them. Moreover, there is a law enabling the pastor or overseer of the parish to remove the children of careless parents, and board them with others who will teach them. This is done at the expense of the parish when the parents are too poor to pay. At Reykiavik there is a college with six professors, embracing a complete classical, literary, and scientific course; there is also a school of theology with three professors, and a school of medicine with two. Students in law and philology go to Copenhagen. Recently a library has been formed in Reykiavik, which comprised 10,000 volumes in 1866. Two political journals were published in Reykiavik in 1866: the *Thjotholfr* or "National," weekly, and the *Islandingur*, fortnightly. The *Northanfari*, a weekly, was published at Akureyri. The new royal charter granted on Jan. 5, 1874, which went into operation on Aug. 1 of that year, gives to Iceland a minister residing in Copenhagen and responsible to the *althing* for the acts of the administration in Iceland. The executive government of the island is vested in the *stiftamtmand* or governor general, residing at Reykiavik, and having under him three deputy governors, residing respectively in the northern, western, and eastern amts, while the *stiftamtmand* himself has immediate charge of the southern. The amts are divided into counties or *sýsla*, each having its own chief officer or *sýselman*. All these officials are appointed by the crown. In each county there is a court presided over by the *sýselman* and two assessors; and from its decisions there is an appeal to the supreme court and the chief justice at Reykiavik. For the revenue there is a *landfoged*, who is both collector general for the whole country and town collector for the capital. Akureyri, recently created a commercial town, has also its local collector or *foged*. The legislative authority, in everything that does not relate to the general interests of the monarchy, is vested in the *althing*, composed of 36 members, 30 of whom are elected by popular suffrage and 6 nominated by the crown. The ecclesiastical establishment, which is exclusively of the Lutheran faith, consists of the bishop of Reykiavik, who with the governor general forms the spiritual court, and 20 arch-deaconries, subdivided into 196 livings. Attached to this is the pastoral seminary at Reykiavik. The clergy are appointed by the crown, subject to the consent of the bishop. Their

parishes for the most part embrace very large districts, and their revenues being utterly insufficient for their support, they have recourse to farming; they have the reputation of being the best blacksmiths in Iceland. There are six medical districts, with medical officers stationed at Reykiavik, Vatnsdalr, and Akureyri, a fourth in the west, a fifth in the south, and a sixth in the Vestmanna islands. Quite recently three missionary stations have been established by the Roman Catholic church. Christianity was voted the national religion in 1000 by the althing. The island was afterward divided into the two bishoprics of Holar and Skalholt. "The bishops," says Baring-Gould, "were elected by the althing, and even the saints were canonized by popular acclamation." With the introduction of the church came the knowledge of Latin letters. In the year 1057, Isleif, bishop of Skalholt, introduced the art of writing with the Latin alphabet. Monasteries, hospitals, and schools were established. Several monks, especially the Benedictines of Thingeyra monastery, contributed largely to the literature of Iceland's golden era. In 1551 the Lutheran form of worship was introduced by Christian III., and after much bloodshed became the only established religion; but much of the old ceremonial still remains. There is no evening service, and the morning service is still known as "the mass;" the minister retains the old chasuble and cope, and over the altar can be seen triptychs, crucifixes, and pictures of saints.—Iceland was discovered in 860 by Naddoddr, a Norwegian viking, who called it Snjaland (Snowland). In 864 it was visited by Garthar Svafarsson, a Swede, who sailed around it and wintered on the east shore of Skjalfandi bay, and called his discovery Garthaskolmr. Enticed by the description which he gave of it, Floki, another viking, sailed into Vatnsfiord in the west, and took possession of a portion of land. But the loss of his cattle during the winter compelled him to break up his settlement. After spending another winter at Hafnarfjörthr, he returned to Norway in the summer. The island received its present name from him; and the glowing account given of it by some of his companions induced two Norwegian chieftains, Hjørleifr and Ingolfr, to visit it. They formed the first permanent settlement in 874 at Reykiavik, and other chiefs with their retainers and thralls soon followed them. The *Islendinga bók*, the earliest monument of Icelandic literature, says that the first colonists, who were all pagans, found that they had been preceded by Culdee anchorites and Irish settlers, who abandoned the island on the arrival of the pagan Norsemen. The report of an Irish monk had first led several of his brethren to sail for the north, touching at the Faroe islands, and reaching Iceland in 725, where they settled on the islet of Papoen on the E. coast, and at Papye in the south. They were called Papar by the Norsemen, and left behind them bells, crossiers,

and Irish books. The oppression of Harold Harfagr drove a large number of Norwegian chiefs and their families to Iceland, and this was further increased under the reign of St. Olaf. About 928 Iceland became a republic, and so remained for 300 years. In 930 a code of laws was adopted, and an annual meeting of the bonders was fixed for midsummer on the plains of Thingvalla; this gathering was called *althing*. In 1262 the majority of the people took an oath of allegiance to Haco, king of Norway, Iceland remaining independent, with her own laws and constitution, and the althing continuing to be the supreme legislative authority. After the union of the Danish and Norwegian monarchies in 1387 the king of Denmark was acknowledged sovereign of Iceland. A provision in the act of union of 1262 stipulated that the king should annually supply the inhabitants with six ship loads of goods. This gradually made the commerce of Iceland a royal monopoly, and in 1602 it was farmed out to a Copenhagen company, in whose hands it remained till 1787. As Iceland only raises cattle and chiefly exports dried fish and wool, its people were thus placed at the mercy of the traders for the bare necessaries of life. The price of goods rose four fold during the next three years, while the price of fish fell, the domestic industries dwindled away, poverty increased, and the population decreased in the same ratio. During these three years 800 persons died of starvation in one district, and 9,000 perished in the whole island. Notwithstanding these facts, the Danish government continued to enforce its own trade laws, and in 1684 a royal proclamation enacted that all traffic must pass through the Copenhagen company, and that on no conditions should the Icelanders trade with others, "neither on land, nor on sea, nor in the harbors or fiords, or in any other place whatsoever." In the 18th century volcanic eruptions repeatedly desolated the land, converting some of the most fertile and populous districts into hideous wastes, and followed by famine and disease. In 1762 an epidemic broke out among the sheep, and 280,000 died or had to be slaughtered. In 1783, the year of the most fearful eruption, 11,000 cows, 27,000 horses, and 186,000 sheep died. The population, which had steadily decreased since 1602, had sunk in 1785 to 39,000, and was further diminished by 9,000 deaths from starvation. In 1786 the project was seriously entertained of removing the remnant of the population from the country, but the royal commissioners demanded instead a relaxation of the trade laws. Commercial freedom came by slow degrees, prosperity returned, and the population increased. In the 16th and 17th centuries, when absolute monarchy was introduced, it was expressly stipulated by the Icelanders that, while acknowledging the sovereignty of the Danish crown, they should retain their own national laws, rights, and freedom. By degrees, however, the legislative powers of

the Icelandic althing were allowed to fall into desuetude. It was formally abolished in 1800, but restored in 1843. Subsequent attempts to supersede it by giving Iceland representatives in the Danish rigsdag, and to make Icelandic taxes flow directly into the Danish exchequer, met with unconquerable resistance. At present, under the royal charter of Jan. 5, 1874, the constitution of Iceland is closely modelled on that of Denmark, and its national independence under the Danish crown is acknowledged. It enjoys an independent judicial as well as legislative system, individual and religious freedom, municipal self-government, and equality of all citizens before the law. Interesting events in the history of Iceland were the discovery of Greenland by Eric the Red, and the establishment there of flourishing but short-lived colonies, and that of America by Leif and others, without any practical results. The one thousandth anniversary of the first permanent settlement of Iceland was celebrated in August, 1874.—The *Landnámabók* records the colonization of Iceland from 870 to 930; the *Sturlunga saga* contains its history from 1100 to 1264; its church history is found in the *Kristín saga* and in the *Biskupa sögur*, or lives of the bishops of Iceland. See "An Historical and Descriptive Account of Iceland" (Edinburgh "Cabinet Library"); S. Baring-Gould's "Iceland, its Scenes and Sagas" (London, 1863); and C. W. Pajkull's "A Summer in Iceland" (London, 1869).

ICELAND, Language and Literature of. *Islenzka*, or *Islensk tunga*, the Icelandic tongue, is the language of the Scandinavians who settled in Iceland in the 9th century. The earliest name given to it in the old writings of the north, in the 11th and 12th centuries, was either the "Danish tongue" (*Dönsk tunga*) or "Northern language" (*Norræna*, or *Norrant mál*). While the language became much altered in Denmark and Scandinavia, it remained essentially the same in Iceland, and the names of Danish, Norwegian, and Northern being no longer applicable to it, the term Icelandic came into use. By Norwegian philologists it is called old Norse or old Norwegian (*gammel Norsk*), while the Danish and German philologists frequently style it old Northern (*old nordisk*, *alt-nordisch*). Icelandic is a daughter of the old Norse proper, the dialect spoken as late as the 11th century in Denmark, Norway, Sweden, and the adjacent islands, and a sister of the old Norse dialect which is the parent of modern Swedish and Danish. It still preserves, with very slight inflectional and orthographical changes, its earliest known form, and is the oldest living language of the Teutonic family. (See GERMANIC RACES AND LANGUAGES.) Although its literary monuments, in their existing shape, do not date quite as far back as the Gothic version of the Bible, it has yet kept many old Teutonic forms which the Gothic had lost even in the days of Ulfilas. Hence its importance in Teutonic philology. In conse-

quence of the invasions of the Northmen, it influenced to a considerable extent the development of the English, and has furnished to the English vocabulary such words as *are*, *take*, *call*, *law*, *till*, to the exclusion of Anglo-Saxon forms. The stationary character of the language is partly explained by its secluded position in an island, and partly by the zealous study by the Icelanders of the ancient songs and sagas. The first characters in which Icelandic was written were the runes (*rúnir*), which are supposed to be adaptations from the Phœnician alphabet. Each letter consisted of an upright stroke, to which various cross strokes were added. The letters were at first only 16 in number. It cannot be ascertained when these characters were introduced. They were chiefly used for inscriptions on stones, wooden sticks, weapons, and household utensils, and hardly for literary purposes proper. At the time of the introduction of Christianity they were superseded by the Roman alphabet, in the form then used by the Anglo-Saxons and Germans. The alphabet, including accented vowels, consists of 36 letters, and differs from the English in not using *c*, *g*, and *w*, and in having the letters *ð* and *p*, the former with the sound of *th* in *this*, the latter with that of *th* in *thin*; the double letter *æ*, sounded like English *i* in *pine*; and lastly the letter *ö*. Until recently also *c* and *g* formed part of the Icelandic alphabet, but they were dropped, as their sounds are fully represented by *s* and *k*. Vowels are either accented or unaccented, and are accordingly either long or short. Masculine and feminine nouns have four declensions each, of which the first two have three variations and the last two only two. The neuters have three declensions, with four variations for the first and two for the second and third. There are two numbers and four cases, nominative, accusative, dative, and genitive. Adjectives have a definite and an indefinite declension, which resemble the old and new declensions of the substantives. Icelandic has only a definite article, which is suffixed to nouns and precedes adjectives, and is inflected in all cases and genders. The first and second personal pronouns have also a dual form. Verbs have active and passive forms; the indicative, infinitive, subjunctive, and imperative moods; an active and a passive participle; and a supine. They have only two simple tenses, past and present; the other tenses are formed with auxiliary verbs. The language has a great facility for forming new words. It does not adopt the common foreign names of science and new inventions, but a telegraph is called either *fréttafleygir*, bearer of news, or *rafsegulthráðr*, electric thread, and a telegram *hraðfrétt*, quick news. The foreign words formerly introduced into Icelandic, chiefly by the clergy, are now so transformed that their origin can hardly be recognized. The dialect of the old Norse spoken in the Faroes, which has been illustrated in collections of ballads

and folk-lore made by Hammershamb and others, differs from the Icelandic chiefly in orthography and in the admixture of Danish words. The best Icelandic grammar is the German edition of Wimmer's *Altnordische Grammatik* (Halle, 1871); the best lexicons are Cleasby and Vigfússon's "Icelandic-English Dictionary" (Oxford, 1868-'74), to which an excellent grammar is prefixed, and for the early skaldic and eddaic poetry Sveinbjörn Egilsson's *Lexicon Poeticum antiquæ Lingua Septentrionalis* (Copenhagen, 1860); the best chrestomathy is Dietrich's *Altnordisches Lesebuch* (Leipsic, 1864).—The Icelandic literature, which, with the exception of a few unimportant Norwegian productions, was written wholly in Iceland or by Icelanders, may be divided into two very marked periods, the ancient and the modern. The first terminated a century after the fall of the republic; the other comprises the period intervening between that date and the present time. Soon after the settlement of the island the genial influence of free government caused a marked development of the national spirit, which was early exhibited in the field of letters. The climate, as well as the isolated position of the island, had also much to do with it. In the long evenings of a long winter, an intelligent people would naturally have recourse to literature; and as soon as the introduction of Christianity brought with it the knowledge and use of the Latin alphabet, the earliest employment of the new gift was in writing out the pagan songs which had been orally transmitted from one generation to another. In such a manner the priest Sæmund Sigfússon, called "the learned" (1056-1133), or some other early scholar, compiled the elder or poetic Edda. (See EDDA.) Besides these, the poetry that has come down to us from the days of the republic consists generally of songs of victory or of praise, elegies, and epigrams, in which latter the old skalds especially excelled. The most noted skalds of the 10th century are Bersi Torfusson, Egill Skallagrímsson (904-990), Eyvind Finsson, Glúm Geirason, Kormak Oegmundarson (died 967), Gunnlaug Hromundarson (983-1012), Hallfred Ottarson (died 1014), Thord Sigvaldaskald, and Thorleif Hakonaraskald. The 11th century was very prolific of poets; we have Arnor Thordarson, Einar Helgason, Eirík, Gísli Íllugason, Odd, Ottar, Sighvat, Skúli Thorsteinsson, Sneglu-Halli, Hallar-Steinn, Stein Skaptason, Stúfur Blindi, Thjóðólf Arnórsson, Thorarin, and Thord Kolbeinsson. The 12th century presents the names of Böðvar, Einar Skúlason, Hall, Hallbjörn, Ivar Ingimundarson, and a host of others. In the 13th century we find scarcely any names but those of Einar Gilsson, Gudmund Oddsson, Ingjald Geirmundarson, and Olaf Thórdarson, showing that the loss of liberty had begun to affect the labors of the muse. The 14th century has little of value to show except the singular poem *Lilja* ("The Lily"), a song in honor of the Virgin by Ey-

steinn Asgrímsson. Nor were the historians and romancers less numerous. The sagas properly fall into two classes, fictitious and historical. Among the former are the *Völunga saga*, *Nornargests saga*, the *Vilkina saga* (narrating the exploits of Diederich of Bern, and thus belonging to the same heroic cycle as the *Heldenbuch* and *Nibelungenlied*), *Hálfs saga*, "Saga of King Hrólf Kráka and his Champions," "Saga of King Ragnar Lóðbrók" (which contains the celebrated *Lóðbrókarkvæða*, or "Death Song of Lóðbrók"), *Frithiofs saga*, *Hervarar saga*, *Oervar Odd's saga*, the sagas connected with the Arthurian and Carolingian cycles of romance, and Snorri Sturlason's "Younger or Prose Edda." Some of these are in part historical, but it is difficult to distinguish the true from the false. Far more valuable as well as more numerous are the sagas of the historical class. They consist of histories in the largest sense of the word, of local and family histories, and of biographies. Of those which relate to Iceland, the most noted are the *Íslendingabók*, by Ari Thorgilsson (1068-1148); the *Landnámabók*, a detailed account of the settlement of the island; the *Kristin saga*, a narrative of the introduction of Christianity into Iceland; *Njáls saga*, a classic composition; *Gunnlaugs Ormstunga saga*; *Viga Glúms saga*; *Egils saga*, the biography of a renowned poet and chieftain; *Kormaks saga*; *Eyrbyggja saga*, an abstract of which has been published by Sir Walter Scott; *Laxdæla saga*; *Sturlunga saga*, a history of the race of the Sturlungar, so important in Icelandic history, by one of its members, Sturla Thórdarson; and *Grettis saga*. The chief sagas relating to other countries are: the *Orkneyinga saga*, a history of the Orkneyian jarls; the *Færeyinga saga*, relating to the Faroes; the *Jomsvíkinga saga*, an account of the sea rovers, whose seat was at Jomsburg near the mouth of the Oder; the *Knyttlinga saga*, a history of the Danish kings from Harald Blaatand to Canute VI.; the sagas of Olaf Tryggvason, one by Odd (died 1200), and the other by Gunnlaug; the saga of St. Olaf; the *Heimskringla*, or "Chronicle of the Norwegian Kings," by the celebrated statesman and historian Snorri Sturlason; and various minor sagas relating to Scandinavia, Russia, Great Britain, and Greenland. The most elaborate codes of law were the *Grágás*, *Járnsíða*, *Jónsbók*, and *Kristinnréttur*. Many of the works enumerated in this list are masterpieces of style, and are still read with delight by modern Icelanders. This list (and it contains but a few of the published sagas) shows the attention paid to the culture of letters in a remote corner of the world, at a time when the whole continent of Europe was sunk in barbarism and ignorance.—The second or modern period of Icelandic literature by no means commences with the termination of the old literature; a long time of utter mental inactivity followed, and the 15th and 16th centuries produced scarcely anything but a few

unimportant religious books. In the 17th century the knowledge of the ancient literature and glory of the island began to revive. Foremost in the movement were Arngrím Jónsson (Jonas, 1568-1648), Gudmund Andrae (died 1654), Rúnólf Jónsson (died 1654), Arni Magnússon (Magnæus, died 1730), and Thormód Torfason (1636-1719). The last named, better known under his Latinized name of Torfæus, was especially zealous in his efforts to disseminate a knowledge of the early history of Iceland. In theology, Gudbrand Thorláksson (died 1627), under whose direction the first complete edition of the Icelandic Bible was issued, Bishop Thorlák Skulson, and Jón Vídalín (1666-1720), the author of a popular collection of homilies, were the eminent names; while jurisprudence was represented by Pál Vídalín (1667-1727). But the true revival of letters dates from the middle of the 18th century, and was coincident with the commencement of an increase in population. During the last hundred years no other nation can show so large a proportion of literary men. Finn Jónsson (1704-'89), author of an elaborate ecclesiastical history of the island, which has been continued by Pétur Pétursson (born 1808), Hannes Finsson (1739-'96), Jón Jónsson (1759-1846), and Arni Helgason (born 1777), were eminent theologians. Antiquities, philology, and the old literature have been largely illustrated by Hálfdan Einarson (died 1785), the author of an Icelandic literary history, Björn Haldórsson (died 1794), the compiler of a large Icelandic-Latin lexicon, which was edited by Rask, Jón Olafsson (1731-1811), S. T. Thorlacius (1741-1815), G. J. Thorkekin (1752-1829), Hallgrím Schéving (1781-1861), Finn Magnusson (1781-1847), Konrad Gíslason (born 1808), H. K. Fridriksson (born 1819), Jón Thorkelsson (born 1822), Gunnlaug Thórdarson (died 1861), and by Gudbrand Vigfússon, now (1874) the foremost Icelandic philologist. An elaborate history of the island, in continuation of the *Sturlunga saga*, has been written by Jón Espólin (1769-1836), while an extensive collection of folk lore has been made by Jón Arnason. The poetical literature of the period has been rendered remarkable by the names of Hallgrím Petursson (1614-'74), the author of the popular passion hymns, Jón Thorláksson (1744-1819), translator of "Paradise Lost," Bjarni Thorarensen (1786-1841), Jónas Hallgrímsson (1807-'45), Sveinbjörn Egilsson (1791-1852), translator of the *Odyssey*, Benedikt Gröndal (born 1826), translator of the *Iliad*, and many others. But the attention of the Icelanders has been largely given to political economy, and the result has been a rapid and marked improvement in the economical condition of the country. Particularly active in this respect have been Jón Eyriksson (1728-'87), Stephán Thórarinnson (1754-1823), Magnus Stephensen (1762-1833), Bjarni Thorsteinsson, Thord Sveinbjarnarson, Baldvín Einarsson (1801-'33), Jón Jónsson

(born 1806), Pál Melsted (1791-1861), and Jón Sigurdsson (born 1811), equally noteworthy as an archæologist and statesman. In natural history we find recorded the names of Eggert Olafsson (1726-'68), whose tour through Iceland in company with Bjarni Pálsson is still one of the most interesting works on the subject, O. J. Hjaltalín (1782-1840), Jón Thorsteinsson (1794-1855), and J. J. Hjaltalín (born 1807). Among the younger writers, most of whose political opinions are liberal, are Gísli Brynjúlfsson (born 1827), Jón Thórdarson (born 1819), Magnus Grímsson, Steingrím Thorsteinsson, Sveinn Skúlasson, and E. Magnússon, who has published English translations of several old Icelandic works. The series of transactions published by the *Lærdoms-lista Félag* in the latter part of the 18th century, and the numerous volumes issued within the past 25 years by the *Íslenzka Bókmenntafélag*, or society of literature, are of great value.—The best sources of information in regard to the old literature are Petersen's *Bidrag til den oldnordiske literaturs historie* (Copenhagen, 1866); Gudbrand Vigfússon's *Um tímatal í Íslendinga sögum* ("On the Chronology of the Sagas of Icelanders," Kaupmannahöfn, 1855); the introductions to Keyser's "Religion of the Northmen," translated by Pennock (New York, 1854), to Laing's version of Snorri Sturlason's *Heimskringla* (London, 1844), and in Dasent's translation of "The Story of Burnt Njal" (London, 1861). The best saga texts are those edited by Munch, Keyser, Unger, and Bugge in Christiania, and by the Arni-Magnæan commission in Copenhagen. A few valuable texts have been published by Möbius and Maurer in Germany, and by the professors in the college at Reykiavik.

ICELAND MOSS (*cestraria Islandica*, Acharius), a lichen common in the north of Europe and America. It consists of a tuft of deeply divided and dentate-ciliate margined, leaf-like, cartilaginous fronds, flattened out and of a lighter color at their base, but above incurved at their edges, so as to render them channelled; in general color they are of a dark olive brown. The fruit (*apothecia*) is borne upon the extremities and sides of the broadest branches, and is very broad and flat with elevated borders. This fruitful condition is only to be met with in the alpine regions of our northern mountains; when the plants occur upon the lower hills, and more especially in dry exposed pastures, they are uniformly infertile. It is possible that these last mentioned forms may yet prove to be distinct species; to settle this point, the occurrence of the apothecia is very desirable. A very bitter principle is resident in the alpine forms as well as in the Iceland moss of the shops; but this is almost wanting in the campestral sorts. As an alleviative to pulmonary complaints the Iceland moss is well known; the principal part of the stock used in medicine is brought from Iceland and Norway. After the intense bitterness, which readily

yields to cold water, has been extracted, boiling water is to be poured upon the mass, when, by keeping up a considerable heat and by several hours' steeping, an abundant and soothing mucilage is given out, and can be used with freedom, the drink being made pala-

Iceland Moss (*Cetraria Islandica*).

table with a little sugar. Hooker says that after being purged of its bitterness the lichen "is dried, reduced to powder, and made into a cake or boiled and eaten with milk, and eaten with thankfulness too, by the poor natives" of those countries where it grows abundantly, "who consider that the very stones yield them bread." The mucilaginous character is owing to a great abundance of lichen starch. Even the bitter principle is tonic and useful in the treatment of disease. Similar alimentary substances are found in other lichens, resulting from the presence of this kind of starch.

ICE PLANT (*mesembryanthemum crystallinum*, Linn.), the common name of a plant originally brought from the Canary islands and Greece. In the Canaries it used to be largely cultivated in order to procure alkali for making glass. Each plant spreads over the ground from a small annual root, and has numerous succulent branches covered with large heart-shaped or ovate, tender, and succulent leaves, the cuticle of both being elevated into many crystalline vesicles which contain a gummy principle insoluble in water; they give the plant the appearance of being covered with hoar frost, and suggested the specific and common name. Cowper calls it the "spangled bean." The sessile flowers are about half an inch across, and have numerous linear, white or purplish petals, but are of little beauty, and only produced in the middle of bright days. It is raised from seed which should be started in a pot or hot-bed, and the young plants set out in a dry warm place. It was formerly much more cultivated than at present. In southern California the ice plant is naturalized, and grows in great quantities; the Spanish inhabitants burn the stems for the sake of the ashes to use in

soap making. Under the name of *glaciale* the ice plant is cultivated in the French kitchen gardens, and is used as an ingredient of soups, as a garnishing for salads, and as a substitute for spinach. (See *MESEMBRYANTHEMUM*.)

ICHNEUMON (Gr. *ἰχνηνέω*, to track), a viverrine carnivorous animal, of the genus *herpestes* (Illiger). The cheek teeth are $\frac{5}{5}$ - $\frac{6}{6}$; the body is long and the legs short; head small and pointed; ears short and rounded; feet five-toed, with sharp semi-retractile claws; a large anal pouch, in which the vent opens. Of the several species described, the best known is the ichneumon of Egypt (*H. ichneumon*, Linn.), known also as Pharaoh's rat. It is a little larger than a cat, with a gait more like a marten, and the long tail ending in a divergent tuft; the muzzle and paws are black, and the fur of the body has each hair alternately ringed with brown and dirty yellow. It is an inhabitant of N. E. Africa, especially Egypt. It was adored by the ancient Egyptians for its antipathy to the crocodile, whose eggs it destroys in great numbers; they saw in it the

Egyptian Ichneumon (*Herpestes ichneumon*).

representative of a benign power engaged in the destruction of one of their most troublesome enemies. Its natural food consists of rats, reptiles, birds, and eggs, but it has no special antipathy to the crocodile. It is itself destroyed by foxes and jackals. The ichneumon is frequently domesticated in Egypt, where it is used like the cat in ridding houses of rats and smaller pests; it forms attachments to persons and places, and recognizes with signs of pleasure the caresses of its master. The mongous of India (*H. mungos*, Linn.) is a little smaller than the ichneumon, paler and more grayish, and with a pointed tail; it has a singular antipathy to serpents, which it destroys whenever it can, not hesitating to attack even the deadly cobra de capello; against the bite of the latter it is said to find an antidote in the *ophiorrhiza mungos*, a root which is considered in Ceylon as a specific against the cobra's bite in man. It is as mischievous, and in the same way, as the polecat and weasels. The garangan of Java (*H. javanicus*, Geoffr.) is chestnut brown, with yellowish

white spots; its habits are the same as in the other species, and it is expert in burrowing; it is easily domesticated, and is used for destroying rats.

ICHNEUMON FLY, an extensive tribe of the pupivorous family of hymenopterous insects, of great importance in the economy of nature on account of their destruction of insects injurious to vegetation, and very interesting from the peculiar manner in which this purpose is effected. They are perfect parasites, depositing their eggs within the body of living insects, which are devoured by the larvæ hatched within them. Their forms are various, but they generally have an elongated body, with a terminal, long, divided, bristle-like appendage, and filiform antennæ which have a constant vibratory motion; the prevailing colors are black, rufous, and yellow, with lines and spots of white. The head is prominent; the mandibles corneous; the wings four, of thin membrane and horny ribs or nervures, the anterior long-est, narrow at the base and dilated at the ex-

Ichneumon Fly.

tremity; the abdomen begins between the two posterior legs; the feet are long and slender. It is difficult to detect the sexes except by the ovipositor; this instrument is short or long according as the eggs are to be deposited in the bodies of caterpillars on the surface of the ground or to be thrust down into their living nidus through a nest or deep crevice; in the former it is retractile and lodged in a groove on the under side of the body, in the latter often longer than the body, consisting of a central oviduct and two lateral protecting appendages coming from the last abdominal segment. The eggs are hatched in the body of the larva, and the young consume the fatty matters in the interior of the victim, without injuring the vital organs; many eggs are often deposited within the same larva; the young undergo transformation within the living insect, or eat their way through the skin and spin their pupa cases on the outside, from which after a time they come out perfect insects. The larvæ selected for this deposition are so enfeebled by the parasites that they perish without going

into the pupa state. A common example is met with in the large green caterpillar, with a horn on the last segment, generally called the potato worm; this is a favorite nidus for the eggs of a minute black ichneumon fly; the young, hatched within its body and devouring its substance, eat through the skin, and spin their pupa cases so thick upon the outside as almost to cover the back and sides of this four-inch caterpillar; each case is attached to the skin by a short delicate filament, and the place of exit of each larva is indicated by a black dot; this caterpillar is often seen crawling about and eating, almost covered with a colony of these tiny silvery white pupa cases, from which in about a week the shining ichneumon flies appear; the caterpillar does not enter the pupa state, but dies exhausted. These flies are generally rapid in their movements, and are taken with difficulty except when depositing their eggs; they occur in flowers, on trees and walls, in houses, and wherever the desired larvæ are found. The perfect insects live upon the pollen and honey of flowers, and do not attack other insects except to make a deposit of eggs; they are of all sizes, from a fraction of a line to more than an inch long; the species are exceedingly numerous, there being about 1,500 in Europe alone. The larvæ are without feet, parasitical and carnivorous. The chalcidians, allied to the ichneumon flies, are extremely small; they puncture the eggs of other insects and deposit their own tiny ones in them. We can hardly estimate the benefits conferred upon man by these apparently insignificant insects; their instincts lead them to do for man's advantage what all his contrivances could not effect; the best known destructive insects kept in check by them are the pine weevils, the lackey caterpillars, the grubs of many wood eaters of their own order, the gall insects, the Hessian fly, and hosts of others which would overrun the forests and fields were it not for these diminutive creatures.

ICHOLOGY (Gr *ιχνος*, a footprint, and *λογος*, discourse), the name applied to the modern science of fossil footprints, or ichnolites. See FOSSIL FOOTPRINTS, and HITCHCOCK, EDWARD.

ICHTHYOLOGY (Gr. *ιχθίς*, a fish, and *λόγος*, discourse), the branch of zoölogy which treats of fishes, the lowest of the great divisions of the vertebrate animals. The class of fishes cannot be said to have been arranged in a strictly natural manner by any systematist, and such an arrangement is impossible until their external and internal structure and embryonic development are better understood; and until zoölogists are better agreed as to what constitutes family, ordinal, generic, and specific characters, little harmony of arrangement can be expected. Most classifications of fishes up to the time of Cuvier (including his) were based on the organs of locomotion and the external integument; after him appeared the anatomical arrangement by J. Müller. The older systems were very imperfect, from the ignorance of fos-

sil forms, which supply many links otherwise wanting in the chain of ichthyological characters. Aristotle, in the 4th century B. C., first reduced ichthyology, as he did the other branches of zoölogy, to scientific form; he was well acquainted with the structure and external characters of fishes, which he distinguishes from cetaceans, laying special stress upon the organs of respiration and locomotion and the scaly covering; he gives the names of 117 species, entering into interesting details on their habits. The system of compilation without observation prevailed until the middle of the 16th century, when Belon, Rondelet, and Salviani laid the foundations of modern ichthyology. Belon gives rude figures of 110 species, Salviani excellent engravings on copper of 99, and Rondelet woodcuts of 234 species, in all three mostly fishes of the Mediterranean. Gesner in the same century borrowed the descriptions of the last mentioned authors, and added some of his own, in his *Historia Animalium* (1551-'6), all arranged in alphabetical order without any attempt at method, embracing however many foreign fishes. Ray and his pupil Willughby, English naturalists of the 17th century, in their *Historia Piscium* (1686), gave the first attempt at a natural classification of fishes, founded upon the consistence of the skeleton, the form, the teeth, presence or absence of ventral fins, number of dorsals, and character of the fin rays. They divided fishes into cartilaginous and osseous; though their genera are not well defined, the species are so well described that it is generally easy to refer them to their proper place in subsequent systems; the whole number of species is 420. The second volume consists of well executed, tolerably accurate plates. This work forms an epoch in the history of ichthyology, which from this time began to assume a methodical arrangement. Passing over Plumier, Ruysch, Kämpfer, Sloane, Catesby, and many scientific voyagers of this period, we come to Artedi in the first third of the 18th century. This Swedish naturalist completed the scientific classification of fishes commenced by Willughby and Ray, defining genera and giving them appropriate names. In his *Philosophia* he divides the class into four orders, founded on the consistence of the skeleton, the branchial coverings, and the nature of the fin rays, as follows: 1, malacopterygians; 2, acanthopterygians; 3, branchiostegous fishes; and 4, chondropterygians (sharks, rays, and sturgeons). He made a fifth, including cetaceans, which is inadmissible, and the third is badly characterized; the three others are to a certain degree natural. In his *Genera Piscium* he gives names and distinctive characters of 45 genera, founded on the number of branchiostegous rays (of which he was the first to see the value), on the position and number of the fins, on the parts supplied with teeth, on the form of the scales, and on the shape of the stomach and cæcal appendages; most of these genera stand at the present day. In his *Synonymia Pis-*

cium he gives the synonymy of 274 species; his works were published after his death by Linnæus, his early friend, at Leyden, in 1738.—Linnæus, in the first edition of the *Systema Naturæ* (1735), followed Artedi; but in the next (1740) he began to give the number of the fin rays, a method of distinguishing since found of great value. In his 10th edition (1758) he trusted to his own knowledge, creating a new system, defining genera more clearly, and using a scientific nomenclature; the most important change was in removing cetaceans from the class of fishes, in which since the time of Aristotle they had been placed, and in uniting them with viviparous quadrupeds in the class *mammalia*. Brisson, in 1756, had already separated them from fishes. Linnæus, however, committed the error of placing the chondropterygians among reptiles, under the title of *amphibia nantes*, to which in the 12th edition (1766) he added the *branchiostegi* of Artedi (*ostracion*, *lophius*, *tetrodous*, &c.). He also suppressed the division of fishes according to the nature of the fin rays, and substituted one founded on the presence or absence of the ventral fins and their position in reference to the pectorals, a method which violates many of the true relations of these animals. Though Linnæus neglected some of the genera of his contemporaries, and distributed his orders in an unnatural manner, describing only 480 species, his precision of definition and the excellence of his binary nomenclature were of great advantage to the progress of ichthyology, and his division into *apodes*, *jugulares*, *thoracici*, and *abdominales* for a long time held its place in the science. Linnæus gave an impetus to the study of natural history, which resulted in making it interesting to all classes, and in inspiring princes with a desire to extend its domain; national expeditions were fitted out by England, France, Denmark, and Russia, which came back laden with treasures of the deep for naturalists; among the workers in this great field we can only mention the names of Commerson, Sonnerat, Pennant, Banks, Solander, the Forsters, Forskal, Steller, Otho Fabricius, O. F. Müller, and Thunberg; the scientific journals teemed with descriptions of new species of fishes from all parts of the globe.—The next great contributor to ichthyology was the German naturalist Bloch, whose celebrated work on the "Natural History of Fishes" consists of two parts essentially distinct; the first, the "Economic History of the Fishes of Germany," appeared at Berlin in 1782-'4, in 3 vols. 4to, with 108 folio plates; the second, the "History of Foreign Fishes," in 1785-'95, in 9 vols. 4to, with 324 folio plates; both were translated into French in a few years after each volume appeared. Of German fishes he describes 115 species, mostly observed by himself. As he was little conversant with the anatomy of fishes, some of his genera are based on purely artificial characters, while others are remarkably correct. He follows the method of Lin-

næus, bringing back the *amphibia nantes*, however, into the class of fishes, and dividing them, with Artedi, into *branchiostegi* and *chondropterygii*.—Comparative anatomy had made considerable progress toward the end of the 18th century, when Lacépède began his researches (1798–1803). He divides the class into cartilaginous and osseous fishes, in each of which subclasses he makes four divisions: 1, with neither opercula nor branchial membrane; 2, without opercula, and with a branchial membrane; 3, with opercula and without branchial membrane; and 4, with both opercula and branchial membrane. In each of the eight divisions he adopts the orders of *apodes*, *jugulares*, *thoracici*, and *abdominales*, according to the absence of ventrals, or their position on the throat, thorax, or abdomen. The natural history of fishes in Sonnini's Buffon (1803–4) is essentially a copy of Lacépède without acknowledgment. These works of Bloch and Lacépède supplied the principal foundation for most subsequent systems. The classification of M. Duméril, in his *Zoologie analytique* (1806), resembles that of Lacépède, inasmuch as it lays stress upon the supposed absence of opercula and branchial rays and the position of the ventrals. Pallas, in the third volume of the *Zoographia Russo-Asiatica* (1811), gives a list of 240 species, distributed into 38 genera, with the exception of three taken from Linnæus; he makes two orders, *spiraculata* or chondropterygians, and *branchiata*, forming with reptiles (*pulmonata*) the class *monocardia* (single-hearted or cold-blooded animals). In 1815 Rafinesque published a second ichthyological system in his "Analysis of Nature, or Tableau of the Universe" (1 vol. 8vo, Palermo); though containing many errors, this system is valuable for several true affinities between fishes before and since regarded as widely separated, as for instance that of the *polypterus* with the sturgeon family.—De Blainville in 1816 (*Journal de Physique*, vol. lxxxiii.) published a classification in which fishes are divided into *gnathodontes* or osseous and *dermodontes* or cartilaginous, the latter distinguished by having teeth adherent only to the skin; the former include the *heterodermes* or *branchiostegi*, and the *squammodermes* or common fishes; in the subdivisions the Linnæan character of the position of the ventrals is adopted, and the families are established principally on the form of the body; it does not employ the Lacépèdian characters taken from the opercula and branchial rays.—Cuvier in 1817, in his *Règne animal*, divides fishes into chondropterygian and osseous. The former contain the families of suckers (lampreys), selachians (sharks and rays), with fixed branchiæ, and the sturionians (sturgeons), with free branchiæ. In the osseous fishes he suppresses the *branchiostegi*, forming of a portion of them the order *plectognathi*, from a peculiar mode of articulation of the jaws, including the families gymnodonts, scleroderms, and lophobranchs. The remaining

osseous fishes he separates into the orders malacopterygians and acanthopterygians, after Artedi, according as the rays of the dorsal fin are soft or spiny. The soft-rayed order he distributes into families according to the Linnæan method of the position of the ventrals, disregarding entirely characters drawn from the opercula and branchial rays. The spiny-rayed fishes form a single order, with the families tænioids (ribbon fishes), gobioids (blennies and gobies), labroids (bass), percoids (perches, a very extensive family), scomberoids (mackerel-like, also numerous), *squamnipennes* (chætodons, &c.), and the flute-mouths (*fistularia*, &c.). He thus makes in all 22 families, founded on direct observation and comparison, and not simply compiled from previous authorities. Goldfuss ("Manual of Zoology"), in 1820, adopted the four orders of Gmelin, giving to them Greek names, and subdividing them into four families, each according to the shape of the head, mouth, or body, or other external character.—Thus far the systems have been little more than repetitions of the combinations of Artedi, Linnæus, and Lacépède. Comparative and philosophical anatomy began to be studied with zeal from the beginning of the 19th century. Oken, Carus, Geoffroy Saint-Hilaire, Spix, Weber, Van der Hoeven, Meckel, Everard Home, Hunter, Tiedemann, and others, wrote upon different portions of the structure of fishes, and the results of their studies began to modify ichthyological classifications. Before mentioning the anatomical and embryological systems, the classification adopted in the *Histoire naturelle des poissons*, by Cuvier and Valenciennes, beginning in 1828 and coming down to 1868, may be alluded to. In this, fishes are divided into osseous and cartilaginous, the latter (or chondropterygians) including the families sturionians, plagiostomes, and cyclostomes. The osseous fishes have the branchiæ pectinated or laminated, with the exception of the lophobranchs, which have them in the form of tufts; all the acanthopterygians have the upper jaw free, including 13 families, and all the malacopterygians except the scleroderms, gymnodonts, and lophobranchs; the malacopterygians are divided into abdominals, subbrachians, and apodes. Cuvier had very abundant materials at his command, embracing the collections of Péron, and those of the expeditions under Baudin, Freycinet, Duperry, Dumont d'Urville, and other French naval officers.—Oken, in his "Physiophilosophy" (Ray society edition), calls the class *glossozoa*, as those animals in which a true tongue makes its appearance for the first time, and *osteozaa*, because in them also the bony system first appears. He makes four divisions, the cartilaginous and apodal *jugulares*, *thoracici*, and *abdominales*, the first two having an irregular and the last two a regular body. Among the systems based upon that of Cuvier are those of Bonaparte, Swainson, Straus-Durckheim, and Rymer Jones. The classification of

C. L. Bonaparte (Rome, 1831) comprised the orders: I., *acanthopterygii*, with 17 families; II., *malacopterygii*, with 12 families; III., *plectognathi*, with 2 families; and IV., *cartilagines*, with 5 families; including in all nearly 3,600 species. The principal improvement on the system of Cuvier is in the series in which the genera are placed. Swainson ("Monocardian Animals," in Lardner's "Cyclopædia," 1838-'9), true to his quinary system, divides fishes into the five orders *acanthopterygii*, *malacopterygii*, *cartilagines*, *plectognathes*, and *apodes*. Straus-Durekheim (*Traité d'anatomie comparative*, Paris, 1843) adopts the eight orders of Cuvier, but subdivides the chondropterygians with fixed branchiæ into three orders, and separates the sharks as the order *sélaciens*, the rays as the order *batoïdes*, and the cyclostomes as the order *galexiens* (from Gr. γαλέξ, lamprey), the term *cyclostoma* having been used for a gasteropod mollusk; he thus makes ten orders. Rymer Jones (in the article "Pisces" in the "Cyclopædia of Anatomy and Physiology," 1847) adopts a modification of Cuvier's system. He makes three divisions: I., *chondropterygii* or cartilaginous fishes; II., *osteopterygii* or bony fishes; III., *dermapterygii*, with skeleton cartilaginous or membranous, and with orders *cyclostomata* (lampreys) and *branchiostomata*.—About 1830 Prof. Agassiz, principally from the study of fossil fishes, established a classification based on the characters of the scales, as follows: order 1, placoids, corresponding to the cartilaginous fishes of authors, but excluding the sturgeons; 2, ganoids, including the sturgeons, and especially the fossil genera with enamelled scales; 3, ctenoids, comprising bony fishes with scales pectinated on the posterior border, and corresponding generally to the acanthopterygians of Artedi, exclusive of the scomberoids, labroids, and pleuronectes; 4, cycloids, including the malacopterygians with the above exceptions, and exclusive of the blennioids and lophioids. This system, soon abandoned as an exclusive one by its author from its placing too much stress on external characters, was valuable as connecting in a continuous series living and fossil fishes, and led to the discovery of many important relations between the scales and the internal organs.—The system of Johannes Müller, as given in the Berlin "Transactions" for 1844, derives its characters from anatomical structure, leading often to combinations without regard to zoological differences. He makes six subclasses: I., *dipnoi*; II., *teleostei*; III., *ganoidei*; IV., *elasma-branchii* or *selachii*; V., *marsipobranhii* or *cyclostomi*; VI., *leptocardii*. Stebold and Stannius adopt this classification in their "Comparative Anatomy;" and a slight modification of it may be found in the third volume of the "Organic Nature" in Orr's "Circle of Sciences," 1855. Owen's classification, mentioned below, and adopted by Sir John Richardson in the article "Ichthyology" of the "Encyclopædia Britannica,"

is based partly on that of Müller.—Vogt, in his *Zoologische Briefe* (1851), divides fishes into the orders *leptocardia*, *cyclostomata*, *selachia*, *ganoïdea*, and *teleostia*. Van Beneden's embryological system (1855) is nearly the same; his orders are *plagiostomi*, *ganoidei*, *teleostei*, *cyclostomi*, and *leptocardii*. Van der Hoeven's classification (as given in the English translation of his "Handbook of Zoölogy," 1858) makes fishes the 14th class of the animal kingdom, and divides them into 5 sections, with 11 orders and 46 families. The sections are *dermopterygii*, *chondropterygii*, *ganolepidoti*, *osteopterygii*, and *protopteri*. Milne-Edwards, in his *Cours élémentaire d'histoire naturelle* (1855), divides fishes into osseous and cartilaginous; the former includes the orders *acanthopterygii*, *abdominales*, *subbranchii*, *apodes*, *lophobranchii*, and *plectognathi*; and the latter, the orders *sturiones*, *selachii*, and *cyclostomi*.—Owen's classification in his "Lectures on Comparative Anatomy" (1855) made the orders *dermopteri*, *malacopteri*, *pharyngognathi*, *anacanthini*, *acanthopteri*, *plectognathi*, *lophobranchii*, *ganoidei*, *protopteri*, *holocephali*, and *plagiostomi* (sharks and rays). His classification of 1866 is somewhat different, as follows: In the division *hæmatocrya*, or cold-blooded animals, including fishes, batrachians, and reptiles, in the fishes he makes subclasses: 1, *dermopteri*, with orders *cirrostomi* (lancelet) and *cyclostomi* (lampreys); 2, *teleostomi*, with orders *malacopteri* (soft-rayed fishes), *anacanthini* (cod), *acanthopteri* (spiny-rayed fishes), *plectognathi* (ostraceans), *lophobranchii* (pipe fish), and *ganoidei*; 3, *plagiostomi*, with orders *holocephali* (chimæra), *plagiostomi* (sharks and rays), and *protopteri* (lepidosiren).—Prof. Huxley places fishes in the lowest of his three great divisions of vertebrates, the *ichthyopsida*, including also the batrachians, from the possession of gills, either permanent or temporary; hence he calls them also branchiate vertebrates. He divides the class *pisces* into six orders: 1, *pharyngobranchii* (amphioxus); 2, *marsipobranhii* (lampreys and hags); 3, *teleostei*, ordinary fishes; 4, *ganoidei*; 5, *elasmobranchii*, sharks and rays; 6, *dipnoi* (lepidosiren).—A new classification was published by Prof. Agassiz in his "Essay on Classification," p. 187 (1857), the result of the systems of Cuvier and Müller and of his own scale method, with additional light from his extensive anatomical and embryological researches. He divides the old class of fishes into four; his 1st and lowest class is myzonts, with two orders, myxinoids and cyclostomes; 2d, fishes proper, with two orders, ctenoids and cycloids; 3d, ganoids, with three orders, celacanth, acipenseroids, and sauroïdes, and doubtful, the siluroïdes, plectognaths, and lophobranchs; he was then doubtful whether this class should be separated from ordinary fishes; and 4th, selachians, with three orders, *chimæra*, *galeodes*, and *batides*. These classes he regards as equivalent to amphibians, reptiles, birds, and mam-

mals.—The following have been the principal cultivators of this science in America: Dr. Samuel L. Mitchill published in vol. i. of the "Transactions of the Literary and Philosophical Society of New York" (1815) a history of 149 species of New York fishes, with many illustrations; he adopts the Linnæan system; other descriptions of his species are in the "Proceedings of the Philadelphia Academy" and in the "Annals of the Lyceum of Natural History of New York." Lesueur has described and exactly figured many species in the Philadelphia academy's "Proceedings." Rafinesque published in the same work, and in his *Ichthyologia Ohiensis* (1820), descriptions of many species which had escaped his predecessors. Dr. Kirtland (1838) described the fishes of the Ohio river, and Dr. Holbrook several years later those of South Carolina. Dr. De Kay in 1842, in his "Zoölogy of New York," divides fishes into bony and cartilaginous, the former having the sections: 1, *pectinibranchii*, with spiny-rayed and soft-rayed abdominal, subbrachial, and apodal orders; 2, *lophobranchii*, and 3, *plectognathi*; the latter include the sections *eleutheropomi*, *plagiostomi*, and *cyclostomi*. Dr. D. H. Storer, in his "Report on the Fishes of Massachusetts" (1839), and in the illustrated edition of the same in the "Memoirs of the American Academy" (1855-'60), and also in his "Synopsis of the Fishes of North America" ("Memoirs of the American Academy," vol. ii., 1846), follows the arrangement of Cuvier. These works are of great value to the student of North American ichthyology. The Wilkes, North Pacific, and Japan expeditions sent out by the United States government, and the various explorations by land for the survey of the Mexican boundary, the Pacific railroad route, and military and civil roads, have added largely to the materials, both foreign and native, at the disposition of American ichthyologists; these have been worked up principally by Messrs. Baird and Girard of the Smithsonian institution, where the collections are deposited. The results are published in the government reports on the naval expeditions, in vol. x. of the "Pacific Railroad Reports," in vol. ii. of the "Mexican Boundary Survey," and in the publications of the Philadelphia academy.—The disposition to make new genera and subdivide old ones is carried to a puzzling extreme in ichthyology as well as in other departments of zoölogy; and the prevalent system of placing the name of the genus maker after the species, by whomsoever and whenever described, offers a premium for naturalists to make the greatest number possible of new genera. In getting rid of the too great condensation of Linnæus, naturalists have fallen into the worse extreme of too extensive subdivision. For details on the structure and physiology of fishes, see FISHES.—FOSSIL ICHTHYOLOGY. Fishes are by far the most numerous of the vertebrates found in the strata of the earth, extending

from the Silurian epoch to the tertiary; their number, excellent state of preservation, and remarkable forms, render fossil fishes of great interest in explaining the changes of our planet's surface, and in completing the chain of ichthyic relations. The classic work on fossil fishes is the *Recherches sur les poissons fossiles*, by Prof. Agassiz (1833-'43); in this magnificent work about 1,000 species are described, with accurate and elegant illustrations, the result of his examinations of more than 20,000 specimens in the cabinets of Europe. He divides fossil fishes into the four orders of ganoids, placoids, ctenoids, and cycloids, according to the structure and form of the scales, these portions of the external skeleton being generally well preserved; the orders he divides into families according to the structure and position of the fins, the form of the bones of the head and of the teeth, and the structure of the gill covers and of the spinous fin rays. His classification is as follows: order I., *ganoides*, characterized by osseous plates covered with enamel (see GANOIDS); order II., *placoides*, with tabular scales, like sharks and rays; order III., *ctenoides*, having many living representatives, with scales serrated on their posterior margins; order IV., *cycloides*, with elliptical or circular scales without serrations. The first order is most abundant from the old red sandstone to the chalk formation; the second extends from the Silurian through the tertiary epochs; the last two are not found anterior to the chalk, from which they extend through the tertiary strata. For details on fossil fishes, see the geological works of Hugh Miller.

ICHTHYOSAURUS (Gr. *ἰχθύς*, fish, and *σαῖρος*, lizard), a gigantic fossil marine reptile, belonging to the order enaliosaurians of Conybeare. The body was fish-like in form, with a large head, neck of equal width with occiput and thorax; the vertebræ had biconcave articular surfaces, as in fishes and the perennibranchiate reptiles; the paddles, four in number, were comparatively small, resembling in form those of cetaceans, but in the number of digits and of their constituent bones and appended bifurcated rays they came near the structure of the fins of fishes; the tail was long, the vertebræ gradually becoming smaller and flatter toward the end, and probably margined with a tegumentary fin expanded or in a vertical direction; the tail was doubtless the principal organ of locomotion, and presented the saurian character of length and gradual diminution, being cetacean in its partially tegumentary nature, and fish-like in its vertical position. According to Dr. Buckland, the skin was scaleless and finely wrinkled, as in cetaceans. The skull is like that of the dolphin, with a smaller cerebral cavity and an unanchylosed condition of the cranial bones; the intermaxillaries are greatly developed, and the orbits immense, surrounded by numerous large sclerotic plates; in the convex articulating surface of the occiput, the solid structure of the back part of the skull,

and the massive proportions of the jaws and the bones with which they are articulated, we see crocodilian affinities. The nostrils are a short distance in front of the orbits; the teeth are situated in an alveolar groove with their bases free, and separated by partial ridges, the roots being implanted much as in the crocodile; hence this reptile is placed by Prof. Agassiz in the order of rhizodonts. The structure of the hyoid apparatus indicates that it was an air breather, with a slightly developed tongue, and that it obtained its food in the water, having an apparatus, as in the crocodile, to shut off the cavity of the mouth from the larynx. The ribs are well developed, extending from near the head to the tail, and attached to a large sternum; the clavicles and shoulder blades are strong; the resulting pectoral arch resembles much that of the mammalian *ornithorhynchus*, and is very different from that of the cetaceans, indicating that the anterior limbs were used not only in swimming but in crawling up the shores of the ocean for the purpose of depositing their eggs, &c. The arm and forearm are very short and broad; after these come the bones of the wrist and fingers, arranged as flattened ossicles in series of from three to six, so dovetailed together at the sides

violence; the vertebræ are about 120; the most remarkable character is the equality in size of the fore and hind paddles, and the comparative simplicity of their structure. The *I. tenuirostris* (Conyb.) is characterized by the length and slenderness of the jaws, as in the gavial; this, with the flat head and large orbits, gives to the skull, as Owen says, the appearance of that of a gigantic snipe with its bill armed with teeth; the teeth are slender and very numerous, about $\frac{70}{10} - \frac{70}{10}$, and directed obliquely backward; it attained a length of about 15 ft., and was rather slender in its proportions. Six other species, and details on all, will be found in Prof. Owen's "Report on British Fossil Reptiles to the British Association," in 1839. Their remains extend through the whole of the oolitic period, including the lias and oolite proper to the Wealden and chalk formations, in Great Britain and central Europe. For fuller details the reader is referred to the writings of Conybeare, Cuvier, and Buckland. These reptiles, of gigantic size and marine habits, must have been very active and destructive; their food, as indicated by the bones and scales found with their remains, consisted principally of fishes. From the great size of the eyes, they could probably see well

Skeleton of Ichthyosaurus.

as to form one powerful framework. The pelvic arch is not articulated to the spine, but was merely suspended in the muscles, as in fishes; the posterior limbs or paddles are generally considerably smaller than the anterior, and would seem to have been more serviceable in terrestrial progression than in swimming. The best known species, *I. communis* (Conybeare), grew to a length of 20 ft.; the large conical, longitudinally furrowed teeth are from 40 to 50 above on each side, and 25 to 30 below; the jaws are prolonged and compressed, the vertebræ about 140, with the anterior paddles three times as large as the posterior; like all the species, this is found in the secondary formations, principally in the lias and oolite of England. The *I. intermedius* (Conyb.), the most common and generally distributed of the species, does not much exceed 7 ft. in length; the teeth are more acutely conical, and about $\frac{45}{10} - \frac{45}{10}$; the vertebræ are about 130, and the fore paddles are much the larger. The *I. platyodon* (Conyb.), so called from the greater smoothness and flatness of the crowns of the teeth, must have attained a length of more than 30 ft.; the head is longer than in the preceding species, and the jaws broader and more powerful; the teeth are about $\frac{45}{10} - \frac{45}{10}$, and are frequently found broken as if from its own

by night; being air breathers, like the crocodiles, they no doubt seized their prey near the surface; the immense cuttle fishes of the secondary epoch probably furnished a portion of their food. These strange creatures formed the connecting link between reptiles and fishes, as do the perennibranchiate amphibia in the actual creation; and by some they have been considered, like the latter, as possessors of both gills and lungs, at least in some stage of their existence, and therefore to a certain extent amphibious. This reptile, with the muzzle of a dolphin, the teeth of a crocodile, the head of a lizard, the paddles of a whale, and the vertebræ of a fish, buried for myriads of years, was introduced to the scientific world by Sir Everard Home, in the "Philosophical Transactions" for 1814.

ICOLMKILL. See ΙΟΝΑ.

ICONIUM. See ΚΟΝΤΕΗ.

ICONOCLASTS (Gr. *ἑκονοκλάστης*, from *εἰκών*, an image, and *κλῆν*, to break), in ecclesiastical history, the violent opponents of the veneration of images in the 8th and 9th centuries. The use of images which led to the iconoclastic troubles dates from very remote antiquity. The paintings which adorn the Roman catacombs are now attributed by such archæologists as Lenormant and Marchi to the first three centuries of the Christian era; and those recently discovered in the cemetery of St. Callistus are thought by De' Rossi to belong to the 1st century. But it is still a matter of dispute

when images were first introduced by Christians into public worship. The prevailing opinion is that they passed from the family into the temple at the end of the 3d century, and that their public use became general at the close of the 4th. The visible representation of the cross found its way earlier both into ecclesiastical and domestic life. This custom and the feeling out of which it grew varied widely among different nations. In Egypt and throughout Africa the use of images met with but little favor. Tertullian, Clement of Alexandria, and Augustine discountenanced it. Both the Greeks and Romans favored the fine arts, but there always existed among Christians an aversion toward anything which resembled the old pagan union of art and religion. The first note of the iconoclastic warfare came from Marseilles, where the bishop, Serenus, caused all images to be demolished and cast out of churches. For this he was twice censured by Pope Gregory the Great, who, while blaming the superstitious use of images, advised their employment as a means of instruction for the unlettered who could not read the Holy Scriptures. In the East, Constantine had embellished the public monuments and churches erected by himself in his new imperial city with representations of religious objects taken from the circle of the Old and New Testaments. Very soon this use became interwoven with the whole domestic and public life of the Greek and Asiatic Christians. Churches, together with their books, furniture, and vestments, private houses and public edifices, household utensils and wearing apparel, were profusely ornamented with images of Christ, the martyrs, and Biblical personages. Statues of costly materials adorned the public squares and the approaches to the imperial palaces. The people were not slow in going to extravagant lengths. Reports of miraculous effects produced by some images attracted crowds of pilgrims. In the course of the 6th century it became a custom in the Greek church to make prostrations before images as a token of reverence to the persons whom they represented. The Manichæans had already characterized these practices as idolatry, and the Jews denounced them as an apostasy from the divine law. About the year 600 Leontius, a Cyprian bishop, wrote a treatise against the Jews and in vindication of the lawfulness of the custom. In the next century the Mohammedans wherever they prevailed forbade the worship of images.—Moved by these circumstances, the Byzantine emperor Leo the Isaurian issued a first ordinance in 726, directed not against the images themselves, but against such signs of an idolatrous homage as prostration and kneeling down before them. This measure, counselled by Constantine, bishop of Nacolia in Phrygia, and countenanced by a large number of other eastern prelates, met with resistance from Germanus, patriarch of Constantinople, and from the mass of the people. Besides se-

rious disturbances in many places, the inhabitants of the Cyclades rebelled against the emperor and equipped a fleet. This was destroyed by means of Greek fire, and a new imperial edict was issued in 730, forbidding the use of all images for religious purposes. Germanus now resigned his office and retired into solitude. Leo caused the statues in churches to be burned and the paintings on the walls to be effaced, and fearful riots and massacres occurred in consequence. Pope Gregory II. remonstrated in vain with the emperor, and the Romans refused to comply with the imperial edict. In 732 a council assembled in Rome by Gregory III., condemned Leo and his abettors, and decreed the validity of the relative honor paid to images. The emperor pursued his purpose with relentless severity until his death in 741, when it was taken up with no less zeal by his son Constantine Copronymus. He was opposed by his brother-in-law Artavasdes, who possessed himself of the throne and restored the worship of images. His death in November, 743, restored Constantine to power, which he used to exterminate images and finish the work begun by his father. He assembled at Constantinople in 754 a council of 338 bishops, who after a deliberation of six months pronounced all visible symbols of Christ, except in the eucharist, to be either blasphemous or heretical, and the use of images in churches to be a revival of paganism. This decision was carried out by Constantine, one of whose last acts was to compel every inhabitant of Constantinople to take an oath never again to worship an image. Leo IV., who succeeded him in 775, was no less energetic in putting down image worship; but at his death in 780 the empress regent Irene concerted measures with Pope Adrian I. for the restoration of images. In 787 the second œcumenical council of Nice decreed that "bowing to an image, which is simply the token of love and reverence, ought by no means to be confounded with the adoration which is due to God alone." The same was also true of the cross, the books of the evangelists, and other sacred objects. The contest was prolonged in the East under successive emperors till Theodora assembled a council at Constantinople (842), which confirmed the decisions of the Nicene council, and established the veneration of images among the Greeks, though subsequently the Greek church took the position which it holds to this day that no carved, sculptured, or molten images of holy persons or things are allowable, but only pictures, which are held to be not images but representations. Romé and Italy had already accepted the decree of the Nicene council, which the Latin church accounts the seventh of the general councils.—The term iconoclasts is also applied in history to those Protestants of the Netherlands who at the commencement of the troubles in the reign of Philip II. tumultuously assembled and destroyed the images in many Roman Catholic churches. These tumults be-

gan Aug. 14, 1566, at St. Omer in Flanders, where several churches were desecrated, the images overturned and broken, and the pictures ruined. The insurgents next attacked the cathedral at Ypres, which they also stripped. The excitement speedily spread all over Flanders, Hainaut, and Brabant, and the churches, chapels, and convents of Valenciennes, Tournay, Menin, Comines, and many other cities and towns were sacked. At Antwerp shortly afterward a mob ravaged the cathedral, destroyed the statues, cut into pieces the paintings, the pride of Flemish art, demolished the great organ, the most perfect in the world, overthrew the 70 altars, and carried off the vestments and sacred vessels. The devastation of the cathedral occupied them till midnight, when they sallied forth to deal in the same way with the other churches of the city and its suburbs. For three days these scenes continued at Antwerp, when they were stopped by a few knights of the golden fleece, who with their retainers attacked and dispersed the rioters. From Antwerp the excitement against images spread over the northern provinces, and throughout Holland, Utrecht, and Friesland the churches were ravaged. At Rotterdam, Dort, Haarlem, and some other places, the magistrates averted the storm by quietly removing the images from the buildings. "The amount of injury inflicted during this dismal period," says Prescott, "it is not possible to estimate. Four hundred churches were sacked by the insurgents in Flanders alone. The damage to the cathedral of Antwerp, including its precious contents, was said to amount to not less than 400,000 ducats. The loss occasioned by the plunder of gold and silver plate might be computed; the structures so cruelly defaced might be repaired by the skill of the architect; but who can estimate the irreparable loss occasioned by the destruction of manuscripts, statuary, and paintings?" Motley, in his "History of the Rise of the Dutch Republic," maintains that the iconoclasts committed no act of plunder nor of outrage on persons. He says: "Catholic and Protestant writers agree that no deeds of violence were committed against man or woman. It would be also very easy to accumulate a vast weight of testimony as to their forbearance from robbery. They destroyed for destruction's sake, not for purposes of plunder. Although belonging to the lowest classes of society, they left heaps of jewelry, of gold and silver plate, of costly embroidery, lying unheeded upon the ground. They felt instinctively that a great passion would be contaminated by admixture with paltry motives. In Flanders a company of rioters hanged one of their own number for stealing articles to the value of five shillings. In Valenciennes the iconoclasts were offered large sums if they would refrain from desecrating the churches of that city, but they rejected the proposal with disdain. The honest Catholic burgher who recorded the fact, observed that he did so because of the many mis-

representations on the subject, not because he wished to flatter heresy and rebellion." The whole time occupied by this remarkable outbreak was less than a fortnight. It was warmly disapproved of at the time by William of Orange, Egmont, and the other statesmen of the patriotic party in the Netherlands. Its immediate effect was to detach the Catholics from the national cause, and it was probably the principal means of preventing the southern provinces of the Netherlands from becoming independent of Spain in concert with the seven northern provinces.

ICTINUS, a Greek architect, contemporary with Pericles. He was chief architect of the Parthenon, and built the temple of Apollo Epicurius near Phigalia in Arcadia. The former was completed in 438 B. C., and the latter probably about 431. He also built the fane at Eleusis in which the mysteries were celebrated. All these edifices were in the Doric style. No details of his life remain.

IDA, a W. county of Iowa, drained by branches of Little Sioux river; area, 432 sq. m.; pop. in 1870, 226. Grain, potatoes, and sorghum are the principal crops; cattle raising is carried on to a considerable extent. The productions in 1870 were 9,239 bushels of wheat, 8,510 of Indian corn, 6,058 of oats, 2,511 of potatoes, and 1,887 tons of hay. The value of live stock was \$34,867. Capital, New Ida.

IDA. I. A mountain range (now Kas Dagli) of Mysia, forming the S. boundary of the Troad. Its highest peak was Mt. Gargarus, about 5,750 ft. above the sea. The principal rivers flowing from Mt. Ida were the Simois, Scamander, and Granicus. From Mt. Ida Gany-mede was stolen; here Paris pronounced judgment on the beauty of the rival goddesses; and here the celestials stationed themselves to behold the battles for Troy on the plain below.

II. A mountain (now Psiloriti) of Crete, the loftiest of the range which traverses that island, of which it occupies the centre, terminating in three peaks crowned with snow for eight months of the year. Its highest summit is said to be about 8,000 ft. Of the legends with which its name is connected, those relating to the infancy of Zeus are the most celebrated.

IDAHO, a territory of the United States, situated between lat. 42° and 49° N., and lon. 111° and 117° 10' W., bounded N. by British Columbia, E. by Montana and Wyoming, S. by Utah and Nevada, and W. by Oregon and Washington. The extreme length N. and S. on the W. boundary is 485 m. and along the Wyoming border 140 m., and the breadth varies from less than 50 m. on the north to nearly 300 m. on the south; area, 86,294 sq. m. The eastern boundary line is irregular. Commencing at the north, it runs S. along the 116th meridian to the crest of the Bitter Root mountains (about lat. 47° 45'); thence it follows S. E. and E. the crest of those and of the Rocky mountains to the 111th meridian on the Wyoming border, and thence runs S.

to the Utah border. The territory is divided into nine counties: Ada, Alturas, Boise, Idaho, Lemhi, Nez Percé, Oneida, Owyhee, and Shoshone. The principal towns are Boise City (the capital), Idaho City, Malade City, and Silver City in the S. part, each having in 1870 less than 1,000 inhabitants, and Lewiston at the junction of the Snake and Clearwater rivers. The population of the territory in 1870, exclusive of tribal Indians, was 14,999, including 4,274 Chinese, 60 colored, and 47 Indians; 12,184 were male and 2,815 female; 7,114 native and 7,885 foreign born; 897 males and 798 females were between 5 and 18 years of age, 9,431 males (3,288 native and 6,143 foreign) from 18 to 45, and 10,313 (3,680 native and 6,633 foreign) 21 years old and upward. Of the natives, 946 were born in the territory, 804 in New York, 550 in Ohio, 536 in Missouri, 479 in Utah, 416 in Pennsylvania, 400 in Illinois, 348 in Oregon, and 312 in Iowa. Of the foreigners, 1,984 were natives of Great Britain, of whom 986 were Irish, 599 of Germany, and 334 of British America. There were 553 persons born in Idaho living in other parts of the Union; 5,557 male citizens of the United States, 21 years old and over, in the territory; 3,293 persons, 10 years old and upward, unable to read, and 3,388 unable to write, including 2,872 Chinese; 4,104 families and 4,622 dwellings; 10,879 persons, 10 years old and over, engaged in occupations, of whom 1,462 were employed in agriculture, 1,423 in professional and personal services, 721 in trade and transportation, and 7,273 in manufactures and mechanical and mining industries. The tribal Indians in 1872 numbered about 5,800. The Nez Percés, 2,807 in number, occupy a reservation of 1,344,000 acres in the N. part of the territory; they are well advanced in civilization, extensively engaged in agriculture, and had two schools in operation, attended by 124 pupils. The Boise and Bruneau Shoshones, numbering 516, and the Bannacks, 521, have a reservation of 1,568,000 acres in the S. E. part of the territory, near the Snake river. These reservations receive limited annuities from the United States, and are in charge of the Presbyterians. The Cœur d'Alènes, Spokanes, Kootenays, and Pênd d'Oreilles, about 2,000 in the aggregate, occupy a reservation of 256,000 acres, 30 or 40 m. N. of the Nez Percés. They receive no annuities, and are largely under the influence of the Catholic missionaries of the Cœur d'Alène mission.—The general surface of the territory is a table land, with an elevation of from 2,000 to 5,000 ft. above the sea, but containing numerous depressed valleys, each watered by a considerable stream, and crossed by mountain ranges or spurs, with peaks rising above the line of perpetual snow. These spurs, branching from the Bitter Root and main chain of the Rocky mountains, and traversing the whole width of the territory, are mostly named from the streams that rise in them or flow along the valleys at their base. In the north, near the

international boundary, are the Kootenay mountains; S. of these is the Cœur d'Alène range, and further S. and along the Clearwater river and its tributaries are the Clearwater mountains. Along the upper Salmon river and at its head waters is the lofty and rugged Salmon River range, and further up the Snake from the mouth of Salmon river are successively found the Weiser, Payette, Boise, Owyhee (in the S. W. portion of the territory), and Saw Tooth mountains. The Bear River mountains are in the S. E. corner, and along the N. portion of the Wyoming border is the Teton range. The Three Buttes are isolated peaks in the S. part, N. and W. of the Snake. The Snake river or Lewis fork of the Columbia and its branches drain the entire territory, except a portion about 120 m. long in the extreme north, which is watered by Clarke's fork, the Spokane, and the Kootenay, and a small tract in the S. E. corner, which is intersected by Bear river. The Snake river, rising in the W. part of Wyoming, after entering Idaho, flows N. W., then bends S. W., and again N. W., making an immense curve through the S. part of the territory, and strikes the Oregon boundary in about lat. 43° 40', after which it flows N. forming the W. boundary of Idaho to about lat. 46° 30', where it turns W. and enters Washington territory. Steamers ascend to Lewiston in Nez Percé co., just above the point where it assumes a W. course. For more than 100 m. above Lewiston the river is shallow and rapid, and navigation is difficult and dangerous; but above the mouth of Powder river it is again navigable for 150 or 200 m. The principal tributaries are the Bruneau from the south, the Malade from the north, and from the east the Boise, the Payette, the Weiser, the Salmon, the Clearwater, and the Palouse. The Boise enters the Snake just below the point where it assumes a N. course; the Payette and Weiser lie between it and the Salmon. The Salmon river rises in the Salmon River mountains near the centre of the S. portion of the territory, and flows N. along the base of the Rocky mountains, turns abruptly W., and after traversing the entire width of the territory joins the Snake near the middle of the W. boundary. The Clearwater rises by several forks in the Bitter Root mountains, and flows W., joining the Snake at Lewiston. The Palouse rises N. of the Clearwater, and empties into the Snake in Washington territory. The Spokane, flowing W. and joining the Columbia in Washington territory, forms the outlet of Cœur d'Alène lake, a navigable body of water of irregular shape, about 24 m. long by 2 or 3 m. wide, which receives the Cœur d'Alène and St. Joseph's rivers from the Bitter Root mountains. Further N. Clarke's fork crosses the territory from E. to W., expanding into a lake about 30 m. long and 5 m. wide near the E. boundary, called Pênd d'Oreille. The river and lake are navigable by steamers through Idaho. The N. E. corner is crossed by the Kootenay, a trib-

utary of the Columbia. Lake Kanisku, about 30 m. long and 6 m. wide, which occupies the N. W. corner of the territory, empties into Clarke's fork. Bear river enters the S. E. corner from Utah, flows N., and bending, sharply S. reënters Utah, and empties into Great Salt lake. The S. W. corner is watered by Jordan creek and other affluents of the Owyhee, an Oregon tributary of the Snake. Three falls in the Snake deserve mention. The American falls are in about lon. $112^{\circ} 45'$, and have a perpendicular descent of 60 or 70 ft. The Shoshone falls further down the stream, and just below the Malade, are surpassed only by those of Niagara and the Yosemite. The river, here 200 or 300 yards wide, is divided about 400 yards above the main fall into six nearly equal parts by five islands, and in the passage between them is precipitated 25 or 30 ft. Uniting below the islands, the water passes in an unbroken sheet over the great fall, a descent of about 200 ft. The Salmon falls, about 45 m. below the Shoshone, are 20 ft. high.—Idaho is rich in the precious metals. The principal quartz mines are in the S. W. part, in Owyhee, Idaho, Boisé, and Alturas counties. In the Owyhee mines, which are the richest, situated S. of the Snake and chiefly on Jordan creek, silver predominates. The other mines, the most productive of which are in Boisé basin, an elliptical depression in Boisé co., 25 m. long from N. to S. and 18 m. from E. to W., produce gold. Placer diggings occur in various parts of the territory; the most important are those of Boisé basin and along the head waters of the Salmon and Clearwater rivers. Gold was first discovered in paying quantities in Idaho on Oro Fino creek, a N. tributary of the Clearwater, in 1860. The Boisé basin mines were discovered in 1862, and the Owyhee mines in 1863. The product of the territory prior to 1868 is stated in J. Ross Browne's "Resources of the Pacific Slope" at \$45,000,000. The subsequent yield, according to R. W. Raymond, United States commissioner of mining statistics, has been as follows: 1868, \$7,000,000; 1869, \$7,000,000; 1870, \$6,000,000; 1871, \$5,000,000; 1872, \$2,695,870; 1873, \$2,500,000; making the total product more than \$75,000,000. Of the yield in 1872, \$2,272,261 was gold and \$423,609 silver; in 1873, \$1,571,733 gold and \$928,267 silver. The gold from Idaho deposited at the United States mint, branches, and assay offices to June 30, 1873, amounted to \$18,389,785 84; silver, \$300,401 74. The census of 1870 returns 254 mines, having 5 steam engines of 82 horse power and 2 water wheels of 52 horse power; hands employed, 1,692; capital invested, \$1,088,640; wages paid, \$503,266; value of materials, \$231,763; of products, \$1,989,341. Of these mines 244 were for the production of gold, of which 7 were hydraulic, 232 placer, and 5 quartz; 10 were quartz mines, producing gold and silver. The returns, however, are admitted to be imperfect. A United

States assay office was established at Boisé City in 1872. There are extensive deposits of salt, coal, and iron ore.—In spring, summer, and autumn the climate is delightful; the days are never sultry and the nights are cool. The winters on the high mountains are accompanied with extreme cold and heavy snow; on the plains and lower mountains they are generally less severe than in N. Iowa, Wisconsin, or central Minnesota. The valleys are mild, visited with little snow, and cattle winter in them without shelter. The average temperature in the W. part of the territory is about the same as in central Illinois, Indiana, and Ohio, and S. Pennsylvania, while in the east it is more nearly that of N. Massachusetts and S. Vermont and New Hampshire. About the sources of the rivers in the Bitter Root and Rocky mountains the fall of rain and snow is considerable, but in the lower valleys in the west it is much less, and agriculture is not generally successful without irrigation. In the extreme north the climate, though less dry, is colder and not well adapted to agriculture; but the temperature does not vary in proportion to the difference of latitude. The lower slopes of the mountains are furrowed with numerous streams, and alternately covered with forests (mostly pine, fir, and cedar) and nutritious grasses. The plains generally produce good pasturage, and the valleys contain broad stretches of meadow land, extending on both sides of the streams by which they are watered to the first rise of table land or mountain, and with irrigation producing good crops of wheat, oats, barley, and the common fruits and vegetables. The climate is not well adapted to Indian corn. The valleys of the Clearwater, Salmon, Payette, and Boisé rivers are large, and generally have good facilities for irrigation; and there are well sheltered and fertile bottom lands on the Weiser, St. Joseph, and Cœur d'Alène, and fertile tracts on the shores of Lakes Cœur d'Alène and Pend d'Oreille. Other important valleys are those of the Bruneau in the southwest, of Wood river in the south, and of Bear river, which contains thriving Mormon settlements. The extreme north is well timbered and has much fertile land. The basin of the Snake is of volcanic origin, and through it the river has cut a vast cañon, varying in depth from 100 to 1,000 ft. The streams that empty into the Snake for some distance below the Shoshone falls sink, and, passing under the strata of lava, fall from the sides of the cañon into the main stream. The greater portion of the basin, though much of it might be rendered productive by irrigation, is a barren waste, producing only sage brush, but along the streams are valleys containing arable land, and the surrounding foot hills are generally covered with bunch grass, affording excellent pasturage. Of the total area of 55,228,160 acres, 16,925,000, according to the estimate of the commissioner of the United States general land office, are

suiting to agriculture; 5,000,000 to grazing; 14,328,160 are sterile, producing only wild sage and occasional tufts of buffalo grass, but mostly reclaimable into pasture and agricultural land by irrigation; 18,400,000, mountains, including 7,500,000 acres of timber land and 8,000,000 of mineral land; and 575,000 acres are covered by lakes. In 1870 there were 77,139 acres in farms, of which 26,603 were improved. The cash value of farms was \$492,860; of farming implements and machinery, \$59,295; amount of wages paid during the year, including the value of board, \$153,007; estimated value of all farm productions, including betterments and additions to stock, \$637,797; value of orchard products, \$725; of produce of market gardens, \$24,577; of home manufactures, \$34,730; of animals slaughtered or sold for slaughter, \$57,932; of live stock, \$520,580. There were 2,151 horses, 371 mules and asses, 4,171 milch cows, 522 working oxen, 5,763 other cattle, 1,021 sheep, and 2,316 swine, besides 624 horses and 49,540 cattle not on farms. The productions were 73,725 bushels of winter and 1,925 of spring wheat, 1,756 of rye, 5,750 of Indian corn, 100,119 of oats, 72,316 of barley, 64,534 of Irish potatoes, 610 of peas and beans, 14 of grass seed, 3,415 lbs. of wool, 111,480 of butter, 4,464 of cheese, 21 of hops, 11,250 gallons of milk sold, and 6,985 tons of hay. The number of manufacturing establishments was 101, having 11 steam engines of 311 horse power and 16 water wheels of 295 horse power; number of hands employed, 265; capital invested, \$742,300; wages paid during the year, \$112,372; value of materials used, \$691,785; of products, \$1,047,624. The only important establishments were 8 quartz mills (value of products, \$523,100), 3 flouring and grist mills, 10 saw mills, 7 breweries, and 2 distilleries. The United States commissioner of mining statistics in 1871 states the number of quartz mills, including those not in operation, at 30, having 344 stamps and 4 arastras, and mostly run by steam; 9 were for the production of gold alone, and 21 for the production of gold and silver. There is a national bank at Boise City, with a capital of \$100,000. No railroads are in operation in the territory, but the Northern Pacific is to cross the N. part.—The government is similar to that of other territories. The executive officers are a governor and a secretary, appointed by the president, with the advice and consent of the senate, for four years; also a treasurer, comptroller, prison commissioner, and superintendent of public instruction created by local law. Legislative authority is vested in a council of 13 members and a house of representatives of 26, elected biennially by the people. The judicial power is vested in a supreme court, district courts, probate courts, and justices of the peace. The supreme court consists of three judges appointed by the president with the consent of the senate for four years, and has appellate jurisdiction. A dis-

trict court, with general original jurisdiction, is held in each of the three judicial districts into which the territory is divided, by a judge of the supreme court. There is a probate court for each county, with the ordinary powers of such courts. Justices of the peace have jurisdiction of inferior cases. The assessed value of real estate in 1870 was \$1,926,565; of personal property, \$3,365,640; total assessed value, \$5,292,205; true value of real and personal, \$6,552,681; taxation not national, \$174,711, of which \$40,594 was territorial, \$132,171 county, and \$1,946 town, city, &c.; public debt, \$222,621, of which \$218,522 (\$33,739 bonded) was county and \$4,099 (\$2,542 bonded) town, city, &c. The receipts into the territorial treasury for the two years ending Nov. 30, 1872, according to the treasurer's report, were \$101,102, including \$16,607 24 on hand at the beginning of the period; expenditures, \$89,817 18; balance, \$11,284 82. The receipts are derived from taxes on property and polls and from licenses. The floating debt at the above date, less cash in the treasury, was \$58,239 73; bonded debt in coin, \$65,058 51, payable Dec. 1, 1875 and 1876, upon which interest to the amount of \$4,471 31 was unpaid. In 1870 there were 25 schools, of which 21 were public, with 33 teachers, 1,208 pupils, and an annual income of \$19,938. In 1872 the number of school districts was 37; public schools, 32; school houses, 26; teachers, 60, of whom 26 were males and 34 females; children of school age, 1,898; number enrolled, 1,416; total expenditures, \$17,219 56. The census of 1870 returns 43 libraries, containing 10,625 volumes, of which 11 with 2,860 volumes were not private; 6 newspapers (1 tri-weekly, 1 semi-weekly, and 4 weekly), issuing 200,200 copies annually and having an average circulation of 2,750; and 15 church organizations (2 Baptist, 6 Episcopal, 2 Mormon, 1 Presbyterian, and 4 Roman Catholic), having 12 edifices with 2,150 sittings, and property to the value of \$18,200.—Idaho was created a territory by the act of congress of March 3, 1863, from portions of Dakota, Nebraska, and Washington territories, comprising an area of 326,373 sq. m., and embracing the present territory of Montana and nearly all of Wyoming. The region within its present limits is a portion of the Louisiana purchase of 1803, and was included first in Oregon and subsequently in Washington territory. The Cœur d'Alène mission was established in 1842, and is situated about 15 m. E. of the lake of the same name. The permanent settlement of the territory did not begin until the discovery of gold in 1860.

IDAHO, a W. central county of Idaho territory, bounded N. by Salmon river, W. by Oregon, and watered by the Little Salmon and other streams; area, 8,500 sq. m.; pop. in 1870, 849, of whom 425 were Chinese. A large portion of the surface is covered with forests of pine. There are several fertile valleys containing good land. On the tributaries of the Salmon

are rich placer mines of gold. The productions in 1870 were 1,111 bushels of wheat, 1,580 of Indian corn, 1,675 of oats, 6,310 of potatoes, and 63 tons of hay. There were 285 horses and 663 cattle. Capital, Washington.

IDELEER, Christian Ludwig, a German mathematician, born at Gross-Brese, in Brandenburg, Sept. 21, 1766, died Aug. 10, 1846. His earliest work was the editing in 1794 of an astronomical almanac for the Prussian government. He taught mathematics and mechanics in the school of woods and forests, and also in the military school, and in 1821 became professor in the university of Berlin. His works include *Historische Untersuchungen über die astronomischen Beobachtungen der Alten* (Leipsic, 1806); *Handbuch der mathematischen und technischen Chronologie* (Berlin, 1825-'6); and *Die Zeitrechnung der Chinesen* (Berlin, 1839).

IDES, in the Roman calendar, the 15th day of March, May, July, and October, and the 13th day of the other months. The eight days preceding the ides were named from it, and styled the 1st, 2d, 3d, &c., day before the ides. Under the empire the senate sat regularly on the ides and on the calends, with the exception of the ides of March, the anniversary of Cæsar's death, which was regarded as a *dies ater*.

IDIOCY, or **Idiotcy**, a term now used to express a condition of mental imbecility, though this idea was not originally contained in the root from which it is derived. The idiot (*ἰδιώτης*) among the Greeks was primarily the private individual, in distinction from the man who participated in public affairs; next, as the educated classes, especially in Sparta, where the word is believed to have originated, alone took part in public life, *ἰδιώτης* came to mean an ignorant or unlettered man; and finally, as ignorance tended to mental degradation, it was applied to one who did not possess the capacity to learn. Numerous attempts have been made to define idiocy, but none of them have been perfectly satisfactory. Dr. H. P. Ayres defines it as "that state of human existence which continuously manifests no signs of intelligence nor instinct." "The type of an idiot," says Dr. Seguin, "is one who knows nothing, can do nothing, wishes for nothing; and each idiot approaches in a greater or less degree this standard of idiocy." In a later work he writes more definitely: "Idiocy is a specific infirmity of the cranio-spinal axis, produced by deficiency of nutrition *in utero* and *in neo-nati*. It incapacitates mostly the functions which give rise to the reflex, instinctive, and conscious phenomena of life; consequently, the idiot moves, feels, understands, wills, but imperfectly; does nothing, thinks of nothing, cares for nothing (extreme cases)." This deficiency of nutrition, occurring before birth, arrests the fetal progress, and gives permanence to the transitory type through which the foetus was passing; a similar arrest of development takes place after birth. The whole being may be affected, or more commonly one

set of organs, as those of speech, &c. In this aspect idiocy may be considered as a prolonged infancy, in which, the infantile grace and intelligence having passed away, the feeble muscular development and mental weakness of that earliest stage of growth alone remain. Dr. Sägert of Berlin, a high authority on the subject, on the other hand, regards it as depending upon a faulty organization of the brain; and Dr. S. G. Howe considers "the pure type of idiocy to be a person whose lack of understanding arises from the smallness of his brain," though acknowledging that for one person in whom idiocy is caused by this circumstance there are many in whom it is occasioned by other causes. It occurs in various degrees, separated by no definite line of demarkation, from the typical condition to a state scarcely distinguishable from normal humanity. Idiocy has been variously classified, according to the point of view or object aimed at. Dr. Seguin recognizes, in different aspects, eight classes, viz.: endemic, when connected with some form of cretinism (see **CRETINISM**); hereditary, when ancestors or tollateral relatives have been affected by idiocy or insanity; parental, when referred to certain conditions of the father or mother; accidental, when occasioned by various post-natal causes; profound, when the ganglia are altered; superficial, when only the peripheral termini of contractility and sensation appear to be affected; organic, when the organs are sensibly altered; and functional, when no organic lesion is observable. The terms "profound" and "superficial" are by others used simply to indicate the degree of idiocy. No particular physical trait is a criterion of this infirmity. It is accompanied by no special shape of the body, though a certain want of proportion is generally observable. The size of the head, except in extreme cases of hydrocephaly or microcephaly, is commonly quite normal, though appearing in infancy too large and later in life too small; nor is its shape a test, though generally somewhat deformed. But any deviation in the relative development of the segments of the brain from the type of a race, or any imperfection in the mode of union of the segments of the skull, indicates *a priori* some anomaly or imperfection of the faculties. Idiocy in infancy is difficult to detect, and can generally be determined only by comparison with a healthy child in the advance toward certain powers that mark the progress of ordinary infancy, as the ability to hold up the head, to sit erect, to use the hands, to take notice, &c.; the lapse of time leaving the idiot further and further behind in the race. In many cases premature senility is exhibited, which is believed to be peculiar to idiots. The symptoms of this condition are various. The body is generally feeble, the circulation particularly in the extremities imperfect, the respiration not deep, and the appetite sometimes abnormal. The gait is accompanied by a sidewise swinging or by forward plunges,

or there is an inability to walk at all. The power of prehension is wanting or imperfect, while spasmodic, mechanical, or automatic motions are common. The touch is dull, less frequently over-sensitive. The taste and smell are oftener indifferent than abnormal. The hearing is passive and limited, sometimes only certain sounds or classes of sounds being heeded, while at others, though the organs are perfect, no sounds are attended to, and the patient becomes practically deaf and consequently mute, from inattention of the will or absence of any desire to hear. The sight is sometimes fixed and vacant, sometimes wandering, and the child may be practically blind from inability of the will to control the vision or from indifference of the mind to the image on the retina. Speech is sometimes wholly wanting; otherwise, more or less imperfect. Idiocy is most frequently complicated with epilepsy and chorea, less frequently with paralysis and contractures, and less frequently still with deafness and blindness; the degree of mental infirmity diminishing in the same order. Perhaps the great feature of idiocy is the inaction or absence of the will, though there is a *vis inertiae*, by some called a negative will, which opposes itself to every attempt to draw the idiot from his indifference and isolation, or from the external trifles upon which he expends the little energy he has. When the disease is not complicated with epilepsy, &c., the idiot is harmless and mild; he has no hallucinations or delusions; he does not perceive wrongly, but only imperfectly or not at all. In some cases, even when the general condition is very low, an extraordinary power in a particular direction, as in music or calculation, is manifested. Idiocy, which is congenital or has its origin in the earlier years, is to be distinguished from dementia, or the loss of the mental powers resulting from disease or the disorganization of the brain in adults. The latter, though resembling idiocy in its apparent results, is incapable of amelioration. The term imbecility is commonly employed to denote a mild form of idiocy, but by Dr. Seguin it is used to designate an arrest of the mental development in youth (which may result in dementia), when vices, habits, and tendencies have been formed to complicate the disease. The causes assigned for idiocy are numerous, and not all of them well ascertained. Inter-marriage of near relatives, intemperance in eating or drinking, and especially sexual congress leading to conception while one or both parties are intoxicated, excess of sexual indulgence or solitary vice, grief, fright, or sudden and alarming sickness on the part of the mother during gestation, the habitual use of water impregnated with magnesian salts, bad and insufficient food, impure air, hereditary insanity, and scrofulous or syphilitic taint, are the most commonly alleged causes of congenital idiocy. The effect on women of the excitements and anxieties of modern life, and of a

false system of education, is stated as the cause of a progressive increase of idiocy noticed by most persons engaged in the treatment of idiots. Convulsions, epileptic fits, hydrocephalus, and other diseases of the brain, smallpox, scarlatina, and measles, blows on the head, or the translation of scrofulous or other eruptive diseases to the brain, are the usual influences which arrest mental development in children. The condition of the mother during lactation likewise has an important bearing on this question.—While among some nations idiots have been regarded with a certain awe as under the special protection of the Deity, until a comparatively recent period they were not deemed capable of improvement, and their condition was generally forlorn. They were suffered to grow up in neglect at home, or were thrown into the almshouses, insane asylums, or houses of correction, and often treated with cruelty. No attempt is known to have been made to improve their condition till the 17th century. When St. Vincent de Paul took charge of the priory of St. Lazarus, he gathered a few idiots, and, fitting up a room in the priory for their accommodation, took charge of them in person, and attempted to instruct them. His labors, though continued for many years, seem not to have been very successful. The next effort was made by the eminent philosopher and surgeon Itard, the friend and disciple of Condillac. In 1799 a wild boy (“the savage of Aveyron”), found in the forests of Aveyron, was brought to Itard, who hoped to find in his instruction the means of solving “the metaphysical problem of determining what might be the degree of intelligence and the nature of the ideas in a lad who, deprived from birth of all education, should have lived entirely separated from the individuals of his kind.” For more than a year he followed a psychological method, but subsequently adopted a system founded on physiology, and labored to develop the intellectual faculties of his subject by means of sensations. The young savage proved to be an idiot of low grade, and hence unfit for the philosophical experiment; but the attempt to instruct him had satisfied Itard that it was possible to elevate the mental condition of idiots. His immense practice, and the severe suffering induced by the malady which finally caused his death, prevented him from devoting much time to the subject; but he had gathered many facts, and these he committed to his pupil, Dr. Seguin, who entered upon the work as a labor of love, and devoted several years to a thorough research into the causes and philosophy of idiocy, and the best methods of treating it. Meantime others had become interested in the subject. In 1818, and for several years subsequently, the effort was made to instruct idiot children at the American asylum for the deaf and dumb in Hartford, Conn.; the measure of success was not large, but their physical condition was improved, and some of them were taught to converse in the sign lan-

guage. In 1819 Dr. Richard Pool of Edinburgh, in an essay on education, advocated the establishment of an institution for imbeciles. In 1824 Dr. Bellhomme of Paris published an essay on the possibility of improving the condition of idiots; and in 1828 a few were instructed for a short time at the Bicêtre, one of the large insane hospitals of Paris. In 1831 M. Falret attempted the same work at the Salpêtrière, another hospital for the insane in the same city. Neither of these efforts met with sufficient success to be continued. In 1833 Dr. Voisin, a French physiologist and phrenologist, organized a school for idiots in Paris, but it was not of long duration. In 1838 Dr. Seguin opened a school in the hospital for incurables of the rue du Faubourg St. Martin, and was soon so successful that the idiots in the Bicêtre were placed under his charge; and within three years he received from the French academy, whose committee had carefully tested his system of instruction, a testimonial of their approval. The previous efforts for the instruction of idiots had been made upon no definite plan, or with a view of testing some philosophical theory of the nature of mind or the original constitution of man. Dr. Seguin, starting with the postulate that idiocy is only a prolonged infancy, consulted nature as to the mode by which the physical powers are cultivated and the mind educated in the infant, and ended by adopting the physiological system of education. This system, considering all the manifestations of life as expressions of functions, and all functions as resultant from a certain organism, assumes that if we could take hold of an organ we should be able to make it perform its function; and teaches that as the organs of sensation are within our reach and those of thought beyond it, the physiological education of the senses must precede the psychical education of the mind. Applying this method to the varying phases of idiocy, each function is to be trained with especial reference to the peculiarities and deficiencies of the individual, and also in its relation to all other functions, with a view to a harmonious whole. Important agencies are pure air and good food, to strengthen and invigorate the system; gymnastic appliances, to exercise the various functions and correct abnormal manifestations; music, imitation, analogy, contrast; the play ground, the workshop, and the farm, which furnish a definite object and lend reality to the exercises, while they initiate the pupil into the actual operations of life. The legs, if they do not bend, may be made to yield by placing the child in a baby-jumper; if the feet refuse to step, they may be taught by making them encounter, with the regularity of a walk, a spring board which alternately receives and throws them back; the gait is regulated by the use of dumb-bells and by conducting the child between the rounds of a horizontal ladder or over planes of various inclinations and conditions of sur-

face, representing the principal difficulties likely to be encountered in nature. The hands are taught to grasp by clapping them about the rounds of an inclined ladder and requiring them to support the weight of the body, or by the use of the balancing pole, which is thrown back and forth between the child and the teacher. The sense of hearing, when wanting, is aroused by music, by surprise sounds, or by sounds connected with some natural desire, as the dripping of water when the pupil is thirsty; the vacant or wandering sight is fixed and awakened by the steadfast gaze of the teacher, by the admission of light at intervals into a dark room, or by the use of the kaleidoscope; the touch, the taste, the smell are trained by appropriate exercises, and the refractory organs of speech are moulded and manipulated until they can utter the desired sounds. The operations are at first passive and in obedience to the will of the teacher; an active performance of the functions is gained by the presentation of motives within the understanding of the pupil. As each sense or organ is carried progressively toward the normal performance of its function, new avenues from without are opened by which ideas, at first concrete, but afterward more abstract, are instilled into the mind. Finding in idiots the infantile fondness for bright colors, teachers avail themselves of it to teach them the distinctions of color and form; noticing their liking for playthings, they furnish them with builders' blocks, cups and balls, and other toys, by which they are instructed in number, form, and size; words, not letters (these, except as a training for the eye, come later), and the meaning of words are taught by pictures and objects. Throughout these processes individual training is alternated with instruction in groups. Simultaneously with the physical and mental training, the idiots are instructed as far as practicable in the social and moral relations and duties by practice and example. The system thus briefly summarized is the one now followed or aimed at in the principal institutions both in the United States and Europe. The enthusiasm of philanthropists has perhaps in some cases led to the expectation of higher results than have been or are likely to be realized. A considerable proportion of those under instruction will make little or no intellectual progress; the mind is too thickly shrouded for the light to reach it. The condition of those suffering from epilepsy is still more hopeless. The training school may slightly improve their physical condition, but that is all. There is however a large number, and those often apparently the worst cases when admitted, who will attain to a considerable degree of intelligence under judicious instruction, and will develop sufficient ability to be capable, under the direction of others, of acquiring a livelihood. A considerable number learn to add, subtract, multiply, and divide, in numbers below 100; but in most cases they grasp the idea of numbers

with great difficulty. In geography they make more progress. In penmanship and drawing many of them are very expert, and most of the girls and some of the boys exhibit considerable skill in needle work. In moral training they have generally exhibited a remarkable susceptibility for improvement. It is estimated that of idiots not affected by epilepsy, who are brought under instruction in childhood, from one third to one fourth may be made capable of performing the ordinary duties of life with tolerable ability. They may learn to read and write, to understand the elementary facts of geography, history, and arithmetic, to labor in the mechanic arts under proper supervision, and to attain sufficient knowledge of government and morals to fulfil many of the duties of a citizen. A larger class, probably one half of the whole, will become cleanly, quiet, able perhaps to read and write imperfectly, and to perform under the direction of others many kinds of work requiring little thought. This class, if neglected after leaving school, will be likely to relapse into many of their early habits. A small number, perhaps the most promising at entering, will make little or no progress. Nor can the result in any particular case be predicted beforehand, and no methods of instruction yet adopted will invariably develop the slumbering intellect, and confirm and correct the enfeebled or depraved will. According to Dr. Seguin, "not one in a thousand has been entirely refractory to treatment; not one in a hundred who has not been made more happy and healthy; more than 30 per cent. have been taught to conform to social and moral law, and rendered capable of order, of good feeling, and of working like the third of a man; more than 40 per cent. have become capable of the ordinary transactions of life under friendly control, of understanding moral and social abstractions, of working like two thirds of a man; and 25 to 30 per cent. come nearer and nearer to the standard of manhood, till some of them will defy the scrutiny of good judges when compared with ordinary young women and men." The institutions generally, under the pressure of applications, do not receive those afflicted with epilepsy, congenital insanity, paralysis, &c., and retain only those that promise improvement. The age of admission in most instances is from 6 to 14, and the term of instruction from 5 to 7 years.—Dr. Seguin continued the instruction of idiots in Paris till 1848, a part of the time in a private establishment. In 1839 he published with Esquirol his first pamphlet, and in 1846 his treatise on the treatment of idiocy, which placed him at once in the front rank of living psychologists. In 1848 he visited the United States, and assisted in the organization and improvement of several institutions for idiot instruction; and he now resides in New York. (See SEGUIN.) In 1839 Dr. Guggenbühl began the study of cretinism in Switzerland, and in 1842 opened his school on

the Abendberg. In the latter year Sägert, a teacher of deaf mutes at Berlin (now imperial councillor and general inspector of the department of instruction of unfortunates in Prussia), began to receive idiotic pupils, and devoted himself to the study of medicine in order the better to understand their physiological condition. The school of Dr. Guggenbühl was discontinued at his death in 1863. It is generally considered that his system was a failure. At present (1874) there are three schools in France: that at the Bicêtre, under the supervision of M. De Laporte, with about 20 inmates; that in the Salpêtrière, under Dr. Delasiauve and Mlle. Nichol, with 50 inmates; and that in the insane asylum at Clermont in the department of Oise, superintended by Dr. Labitte, and having 15 inmates. In Belgium there are separate departments for idiots in the insane asylums at Gheel and at Ghent; the former, under the superintendence of Dr. Bulckens, having 15 idiotic youth, and the latter, under Dr. Inghels, about 40. In Switzerland there are two private training schools for idiots: one in the canton of Bern, under the superintendence of Dr. Appenzeller, opened in 1868, and having 12 pupils in 1874; the other near Basel, under the charge of Dr. Iselin, opened in 1850, and having 15 pupils. In 1863 there were 15 institutions in Germany, mostly private, viz.: at Bendorf, Berlin (two), Hasserode, Neinstedt, and Schreiberhau, in Prussia; Ecksberg and Neudettelsau, in Bavaria; Buschbad, Hubertsburg (two), and Mäckern, in Saxony; Mariaberg and Winterbach, in Würtemberg; and Langenhagen, in Hanover. At present there are 10 schools for idiots in Prussia, some of which are maintained by the state and others by the provinces. The only asylum for idiots in the Netherlands is the medical asylum for idiotic youth at the Hague, opened in 1858, which took its origin from the day school for idiots, opened in 1855. The number of inmates March 23, 1874, was 48 (25 boys and 23 girls), while the day school, which is continued in connection with the asylum, and only receives children residing at the Hague, has 25 pupils. These institutions are supported by subsidies, by contributions, and by fees of pupils. They are under the charge of A. S. Moesveld as director or superintendent, who with his wife has 12 assistants, and of Dr. C. W. Eikendal as physician. The number of teachers is 12, including one instructor in gymnastics and two in handicraft. In Sweden there are three schools for idiots in operation, viz.: at Sköfde in the province of West Gothland, under the superintendence of Miss E. Carlbeck, opened in 1868, and in 1874 having 32 pupils; at Stockholm, under the superintendence of Miss W. Lundell, opened in 1870, and having 20 pupils; at Strömsholm, in the province of Westmanland, under the superintendence of Mr. R. Bruce, opened in 1871, and having 10 pupils. These schools receive only congenital idiots

who give hope of improvement. Two others are about to be opened, at Strengnäs and Gefle. There is a training school in St. Petersburg, and also one at Newcastle, New South Wales, which in 1872 had 132 pupils. The first schools in England were small, and were sustained by some benevolent ladies, in the towns of Lancaster, Bath, Ipswich, and Brighton. In 1847 an effort was made to establish an institution in some degree commensurate with the wants of the class for whom it was intended. In this movement Dr. John Conolly, the Rev. Dr. Andrew Reed, the Rev. Edwin Sidney, and Sir S. Morton Peto distinguished themselves by their zeal and liberality. They first rented a nobleman's residence, called Park house, at Highgate, near London, in 1848, and two years subsequently Essex hall at Colchester. In 1853 the foundation stone of the present capacious and admirably appointed institution at Earlswood, near Redhill, Surrey, was laid, and it was opened in 1855. It now has about 700 inmates, and is under the superintendence of Dr. G. W. Grabham. With it is connected a farm of about 100 acres, and many of the pupils are instructed in farming and gardening, while others are taught mat making, basket making, tailoring, carpentering, and similar employments. Upon its opening the inmates of Park house were removed to it, and ultimately those of Essex hall, which was closed in 1858. The latter was reopened in 1859 as the eastern counties asylum for idiots and imbeciles, and now has about 70 inmates. The western counties asylum was established in 1864 at Starcross, near Exeter; and the Dorridge Grove idiot asylum at Knowle, now known as the midland counties asylum, was opened in 1866. More recently the Royal Albert asylum (northern counties) has been established near Lancaster, occupying a fine building surrounded with ample grounds, and capable of accommodating 500 inmates; it is under the superintendence of Dr. Shuttleworth. These institutions are supported chiefly by subscriptions and donations; pupils are admitted upon payment, and may enjoy the benefits of instruction gratuitously by the nomination of the boards of directors or the election of the subscribers. The private institution of Dr. Langdon Down, formerly superintendent of Earlswood, at Normansfield, near London, has about 50 inmates, and is designed only for the wealthy. Besides these training schools, there are two large asylums near London maintained by the poor-law boards for keeping and feeding idiots and demented. In Scotland, besides the institution established in 1853 on the estate of Sir John and Lady Ogilvie at Baldovan, near Dundee, there is the "Scottish national institution for the education of imbecile children," founded by a society organized for that purpose, and opened in 1862 at Larbert, Stirlingshire, under the superintendence of Dr. David Brodie, who for several years previously had been in charge of a school for idiots in Edin-

burgh. The present superintendent is Dr. W. Ireland, and the number of pupils is about 90. In Ireland an establishment has recently been endowed by Dr. Stewart, to which it was intended to remove the inmates of the asylum for lunatics and idiots at Lucan, near Dublin. The only idiot asylum in Canada was opened in July, 1872, at London, Ontario. It occupies a separate building, accommodating 40 patients, in the grounds of the asylum for the insane, and is under the charge of Dr. Henry Landon, the superintendent of that institution. It is as yet merely a house of refuge, but the present building is to be enlarged, and another provided elsewhere for a training school. In the United States, where there are now 10 institutions, the movement for the instruction of idiots commenced almost simultaneously in New York and Massachusetts. Efforts had been made, in isolated cases (apart from the attempts at the American asylum already referred to), to instruct idiot children in the Perkins institution for the blind in Boston, and in the New York deaf and dumb institution, as early as 1838 or 1839; but the feasibility of organizing an institution for their treatment and training does not seem to have been thought of till the attention of philanthropists was drawn to it by the eloquent letters of Mr. George Sumner, describing his visits to the schools in Paris. These letters were published in 1845, and Dr. S. B. Woodward, long known as the superintendent of the hospital for the insane at Worcester, Mass., and Dr. Frederick F. Backus of Rochester, N. Y., soon after corresponded upon the subject. Dr. Backus was elected a member of the New York state senate in the autumn of 1845, and in January, 1846, read a report which he had drawn up on the subject of idiot instruction, and the necessity of an institution for the purpose. A few weeks later he reported a bill for such an institution. During the same month a bill passed the Massachusetts legislature, appointing a commission to investigate the condition of the idiots of Massachusetts, and report on the necessity of measures for their instruction. The result was the establishment of an experimental school in October, 1848, in a wing of the institution for the blind at South Boston. Dr. Hervey B. Wilbur, a young physician of Barre, Mass., opened a school for idiot children there in July, 1848. The school at South Boston was incorporated in 1850 as the "Massachusetts school for idiotic and feeble-minded youth," and has remained under the supervision of Dr. S. G. Howe. The state makes an annual appropriation of \$16,500, and poor children are admitted without charge upon the recommendation of the governor, besides which there are some paying pupils and a few supported by the states of Maine, New Hampshire, Vermont, and Rhode Island. Facilities are afforded here for employing the inmates in the simpler branches of manufacture. The number under instruction in 1873 was 122; number remaining at the close of the

year, 119; expenditures, \$17,560 38. In 1851 the institution whose organization Dr. Backus had sought in 1846 was finally established, first as an experimental school at Albany, and subsequently as a permanent state institution, the "New York asylum for idiots," at Syracuse. The state in 1855 erected a fine edifice for it in the latter city, at a cost of between \$80,000 and \$90,000, with accommodations for 150 pupils. It has been from the first under the charge of Dr. Hervey B. Wilbur, who was called from Barre to organize the experimental school. It has an extensive farm, and has been enlarged to accommodate 225 inmates. The number of pupils in 1871 was 155, of whom 90 were males and 65 females. The number under instruction in 1872 was 164, of whom 132 were wholly supported by the state, the rest paying wholly or in part for their maintenance; number remaining at the close of the year, 163; number of teachers, 5; other officers, &c., 6; expenditures, \$34,049 59. In 1852 a private school was established at Germantown, Pa., by Mr. J. B. Richards, which resulted in the incorporation in the following year of the "Pennsylvania training school for feeble-minded children." In 1857, having received a grant from the state, and liberal subscriptions from individuals, its trustees purchased a tract of land about a mile from Media, Delaware co., and 12 m. from Philadelphia, and commenced the erection of the building which is now occupied. This institution has a farm of more than 100 acres, and was at first under the supervision of Dr. J. Parish, who was succeeded by Dr. Isaac N. Kerlin, the present superintendent. The number under instruction in 1873 was 249; remaining at the close of the year, 222, of whom 123 were males and 99 females; 84 were supported wholly and 24 partly by the state, 27 by New Jersey, 3 by Delaware, 12 by the city of Philadelphia, 58 by parents or guardians, and 14 by the institution; expenditures, \$53,985 40. There are four departments. The asylum embraces a distinct portion of the building and grounds, accommodating about 25 male inmates, who are only susceptible of habit-training, and only a small proportion of whom can be advantageously employed at work of any kind. A fund has been started to erect a separate building for an asylum. The nursery, also distinct from the other departments, accommodates 32 children of helpless condition, who are attended by experienced nurses. The school department is divided into five classes, and at the close of 1873 included 117 children, who receive from three to five hours' instruction daily. The exercises, while having especial reference to training in articulation, movements, and ideas, differ little from those in schools of the primary and secondary grade for intelligent children. The industrial department embraced 29 boys and 20 girls, who either were only capable of being taught manual labor, or had been through the school

training and could with advantage to themselves be instructed and kept in usefulness. Of the whole number (701) admitted to the close of 1873, there were mutes, 138; semi-mutes, 176; defective in articulation, 204; defective in sight, 142; defective in hearing, 139; unable to walk, 19; of imperfect gait, 344; unable to feed themselves, 74; unable to dress themselves, 158; uncleanly in habits, 269; of destructive habits, 374; epileptic, 157; malformed, 90; scrofulous, 575. Up to July 1, 1872, the improvement had been as follows: taught to speak, 53; articulation improved, 253; taught to read, 254; to write, 146; to feed themselves, 61; to dress themselves, 94; to walk, 5; gait improved, 286; reformed from bad habits, 164; from destructive habits, 302; accustomed to some employment, 241; epilepsy cured, 23; epilepsy improved, 78. From the report for 1870 it appears that of 500 who had enjoyed the benefits of the institution, 81 became capable of earning their own support in domestic service, farming, or certain shop employments, under the guidance of friends; 140 were able to earn a half support; 118 could perform small services of no great value; while 161 were wholly dependent, earning nothing, and evincing an improvement only in their personal habits, in delicacy, language, or movement; 267 proved to be adapted to schools, and 233 were not susceptible of scholastic improvement. In 1857 the "Ohio state asylum for the education of idiotic and imbecile youth" was organized at Columbus as an experimental school, under the superintendence of Dr. R. J. Patterson, who was succeeded in 1860 by Dr. G. A. Doren, the present superintendent. It was permanently established in 1864, when a farm of 130 acres, about 2 m. W. of the city, was purchased, and the erection of a building to accommodate 250 inmates (since somewhat enlarged) commenced, which was occupied in 1868. The number under instruction in 1872 was 312; remaining at the close of the year, 288; teachers, 11; other officers, &c., 4; expenditures, \$84,425 58. This institution is entirely supported by the state, and all pupils are maintained and educated free of charge, except for clothing. The "Connecticut school for imbeciles" was established at Lakeville in 1858, and incorporated by the legislature in 1861; it is under the supervision of Dr. H. M. Knight. The number under instruction during the year ending May 1, 1872, was 55; remaining on that date, 48, of whom 20 were beneficiaries of the state to the amount of \$3 a week. The state has also appropriated money for the erection and enlargement of buildings. The "Kentucky institution for the education of feeble-minded children and idiots" was established at Frankfort in 1860, and is under the superintendence of Dr. E. H. Black. The number of inmates in 1874 was 104. The "Illinois institution for the education of feeble-minded children" was established at Jack-

sonville in 1865 as an experimental school, under the charge of the board of directors of the institution for the deaf and dumb, and was incorporated under its own board of trustees in 1871. It has been from the first under the superintendence of Dr. Charles T. Wilbur, brother of the superintendent of the New York institution. The number under instruction in 1873 was 126; remaining at the close of the year, 100, of whom 66 were males and 34 females; teachers, 4; other officers, &c., 3; expenditures, \$25,777 49. The pupils are divided into seven classes. The expenses of the institution, except for clothing of pupils, are defrayed by the state. The idiot asylum on Randall's island, supported by the city of New York, is under the charge of Mrs. Herbert, matron, and in 1874 had 167 inmates, of whom 91 were males and 76 females; 44 were unimprovable cases; the remaining 123 were receiving instruction in a school opened in October, 1867, and conducted by Miss Mary C. Dunphy (who has been principal from the first), with three assistants. The private institution at Barre, Mass., has since 1851 been carried on by Dr. George Brown. It embraces ample grounds, handsomely laid out, with several buildings, in which the patients are classified according to their condition and the pecuniary ability or inclination of the parents. The number of inmates is about 60, of whom part, as epileptics, &c., are received for medical treatment, part for custody, and part for instruction. A private school was opened in 1871 at Fayville, Worcester co., Mass., by Mrs. O. H. Knight and Mrs. M. A. F. Green, formerly teachers at South Boston. The number of pupils is limited to 12.—The number of idiots in the United States, according to the census of 1870, was 24,527, of whom 14,485 were males and 10,042 females; 3,188 were colored, and 1,645 foreign-born; 140 were also deaf and dumb, 105 blind, and 11 both deaf and dumb and blind. There were 437 under 5 years of age, 1,616 from 5 to 10, 3,088 from 10 to 15, 3,706 from 15 to 20, 6,476 from 20 to 30, 3,938 from 30 to 40, 2,571 from 40 to 50, 2,676 of 50 and upward, and 19 of unknown age. The number in each state is shown in the following table:

Alabama.....	721	New Hampshire.....	325
Arkansas.....	289	New Jersey.....	436
California.....	87	New York.....	2,486
Connecticut.....	341	North Carolina.....	976

VOL. IX.—12

The number of idiots and their proportion to the population cannot, however, be ascertained with any satisfactory degree of accuracy. The census statistics are untrustworthy, both from the different standards adopted by enumerators, and from the difficulty of persuading parents, from whom the returns are usually obtained, that their children are idiots. Some of the worst cases in idiot asylums were brought there by their friends, not as idiots, but as being a little peculiar in their habits. The effort has been made in several states to obtain returns from physicians, clergymen, and town officers, but with very moderate success. So far as these returns go, however, they show a much greater prevalence of idiocy than has been commonly supposed; and it is now generally conceded by competent judges that the number of idiots is greater than that of the deaf and dumb or of the blind, and as great as that of the insane, the proportion being not less than 1 in 1,000 of the population. Assuming this ratio, the number of idiots in the United States would be more than 38,000. According to the census of 1871, the number of idiots and imbeciles in England and Wales in that year was 29,452, of whom 14,728 were males and 14,724 females; but the actual number in those two countries has been estimated as high as 50,000. The number in Scotland is stated at 3,000; in Ireland as high as 7,000. The number of idiots in the Netherlands, according to Dutch authorities, is between 3,000 and 4,000; the census of Norway in 1865 enumerated 2,039. The number of idiots and cretins in Switzerland was estimated in 1868 at 3,800.—Under the common law, "an idiot or natural fool," according to Blackstone, "is one that hath had no understanding from his nativity, and therefore is by law presumed never likely to attain any." "A man is not an idiot if he hath any glimmering of reason, so that he can tell his parents, his age, or the like common matters." His custody and the care of his lands were at first vested in the lord of the fee, but subsequently in the crown, and exercised through the lord chancellor. The sovereign took the profits, supplied the idiot with necessaries, and upon his death restored the estate to his heirs. There was a writ *de idiota inquirendo*, to inquire whether a man was an idiot. The jury, however, rarely found a person an idiot from nativity, but in most cases only *non compos mentis*, in which case a different rule applied. For the present legal status of idiots see LUNACY.—See "Essay on Education," by Dr. Richard Poole (first published in the "Edinburgh Encyclopædia," 1819, afterward in a separate volume, 1825); *Traitement moral, hygiène et éducation des idiots*, by Dr. E. Seguin (Paris, 1846); "Reports of Commissioners on Idiocy in Massachusetts" (Boston, 1848-'9); "Statistical Studies on Idiocy," by M. Hubertz (Copenhagen, 1851); "Mental Alienation and Idiocy in England, Scotland, and Ireland," by Dr. Stark

(vol. xiv. of statistical society's "Journal," 1851); *Traité du goître et du crétinisme*, by Dr. Niepce (2 vols., Grenoble, 1852); "Essay on Idiocy," by Dr. Coldstream (Edinburgh, 1852); *Die Heilung und Verhütung des Cretinismus und ihre neuesten Fortschritte*, by Dr. Guggenbühl (Bern and St. Gall, 1853); "Report of Commissioners on Idiocy in Connecticut" (New Haven, 1856); "Essay on Idiot Instruction," by Dr. Ferd. Kern (*Allgemeine Zeitschrift für Psychiatrie*, 1857); *Die gegenwärtige Lage der Cretinen, Blödsinnigen und Idioten in den christlichen Ländern*, by Julius Desselhoff (Bonn, 1857); "Report on the Education of Imbecile and Idiotic Children," by Dr. H. P. Ayres (vol. xiii. of the "Transactions" of the American medical association, 1862); *Uebersicht der öffentlichen und privaten Irren und Idioten-Anstalten aller europäischen Staaten*, by Dr. Albrecht Erlenneyer (Neuwied, 1863); "Lunacy and Law, together with Hints on the Treatment of Idiots," by F. E. D. Byrne (London, 1864); "The Training of Idiotic and Feeble-minded Children," by Dr. Cheyne Brady (Dublin, 1864); "Idiocy and its Treatment by the Physiological Method," with bibliography, by Dr. Seguin (New York, 1866); "New Facts and Remarks concerning Idiocy," by the same (New York, 1870); "On Idiocy, especially in its Physical Aspects," by Dr. W. W. Ireland (Edinburgh, reprinted from the "Edinburgh Medical Journal" for January and February, 1874); and the annual reports of the various institutions.

IDOCRASE (Gr. *eidēv*, to resemble, and *κρᾶσις*, a mixture), a mineral species of the garnet section of the silicates, resembling other species in its crystalline forms. It occurs variously colored, as brown, sulphur yellow, green, and blue; and of vitreous, frequently somewhat resinous lustre. Its hardness is 6.5; specific gravity, 3.35-3.45. It was first observed in the lavas of Vesuvius, and was called Vesuvian. Numerous localities of it are known in gneiss rocks, serpentine, and granular limestone. It is particularly abundant at Parsonsfield and Phippsburg, Me., occurring in massive forms as well as in crystals.

IDRIA, a mining town of Austria, in the duchy of Carniola, 28 m. N. N. E. of Trieste; pop. in 1869, 3,960. The town is in a deep, narrow Alpine valley, on a small river of the same name. Its quicksilver mines are the second in importance in Europe, and in 1871 produced 6,700 cwt., besides about 1,100 cwt. of artificial cinnabar. The rich hepatic mercurial ore is found in a formation of clay slate forming a bed in compact limestone. The excavations are horizontal galleries diverging from a shaft which has been sunk to a depth of more than 1,000 ft. The entrance is from the *Schloss*, a building within the town. Descent is accomplished partly by about 800 steps cut in the rock, and partly by ladders. The miners are a uniformed corps, 500 in number, and the service is eagerly sought for, the high-

er rate of wages and contingent advantages being balanced against the unhealthiness of the occupation. The mines were discovered in 1497, and are the property of the crown.

IESI. See JESI.

IFFLAND, August Wilhelm, a German dramatist, born in Hanover, April 19, 1759, died in Berlin, Sept. 22, 1814. At the age of 18 he made his début upon the stage at Gotha, in one of Engel's comedies, in which he took the part of an old Jew. In 1779 he joined the theatrical company at Mannheim, and was the leading actor there when in the latter part of 1781 Schiller put into his hands the manuscript of the "Robbers." The play was produced in the succeeding January, with Iffland in the part of Franz Moor, and the success which attended the representation at once brought Schiller into notice, and confirmed the reputation of Iffland. The latter remained in Mannheim till 1796, when he assumed the direction of the national theatre of Berlin. In 1811 he was appointed general director of all the royal plays, and about the same time made an extended professional tour through Germany. His plays, chiefly of the class known as the domestic drama, were very successful in their day, and are still occasionally performed. Among the best of his works are *Die Jäger*, *Der Spieler*, and *Die Hagestolzen*. A collection of 47 of them was published in 16 vols. in Leipsic in 1798-1802, including a memoir of his theatrical career. Volumes containing other pieces were published in 1807-'9 and in 1827; and in 1844 his select works appeared.

IGLAU, a town of Austria, in Moravia, on the Iglawa, 46 m. W. N. W. of Brünn; pop. in 1869, 20,112. It consists of the town proper, which is walled, and three suburbs, and contains a military school, a gymnasium, and several charitable institutions. It has manufactories of woollen goods, tobacco, glass, and paper, and spinning and dyeing works. On July 5, 1436, the convention was concluded here, by which the emperor Sigismund was acknowledged king of Bohemia.

IGLESIAS, a town of Sardinia, in the province and 32 m. W. N. W. of the city of Cagliari; pop. about 6,500. It derives its name from its great number of churches. So many gardens adjoin it that the Sardinians call it *floré di mundu* (flower of the world). The finest of these gardens is at the Dominican convent. The richest lead mine of the island is on Monte Pone, 1,100 ft. high, 1 m. S. W. of the town.

IGLESIAS DE LA CASA, Josef, a Spanish poet, born in Salamanca in 1753, died in 1791. He early published ballads and satirical effusions which made him famous, but his didactic poems subsequent to his joining the priesthood were less popular. The best editions of his works are those of Barcelona (1820) and Paris (1821), and among the later editions there is one in 4 small vols. (1840), which includes a number of poems by other authors.

IGNATIUS, Saint, of Antioch, surnamed Theophorus, one of the primitive fathers of the church, died Dec. 20, 107 or 115, at Rome according to some, but most probably at Antioch, as others have it. He is reckoned one of the apostolic fathers. Eusebius says that he was appointed bishop of Antioch in 69. Baronius and Natalis Alexander make him bishop of the gentile Christians residing in that city, Evodius being at the same time bishop of the Jewish converts. The *Martyrium Ignatii*, which professes to have been written by an eye-witness of his martyrdom, affirms that he was a disciple of St. John, and ordained by the apostles themselves. After having watched over the steadfastness of his flock during the persecution of Domitian, he was condemned by Trajan to be thrown to the wild beasts in the Roman amphitheatre, where, according to the *Martyrium*, he suffered. The Greeks celebrate his feast on Dec. 20, and the Latins on Feb. 1. During his journey to Rome Ignatius wrote seven epistles enumerated by Eusebius and Jerome. They are addressed to the Romans, to Polycarp, and to various Asiatic churches. At present there are fifteen letters extant ascribed to Ignatius. The seven mentioned by Eusebius, according to the shorter Greek recension, are generally accepted as genuine by Roman Catholic theologians; the others are considered spurious. But a warm controversy has long existed between the learned of various Protestant denominations regarding the genuineness of all or some of the first seven. A Syriac version of the epistles to the Ephesians, Romans, and Polycarp was brought from a convent in the Nitrian desert to the British museum in 1843, and edited in 1845 by Cureton. It was maintained by the editor that these are the only genuine epistles of Ignatius; and this conclusion was adopted by Dr. R. A. Lipsius, Bunsen, and some eminent Presbyterian authorities. Episcopal writers for the most part contend that all of the seven epistles are genuine. The best editions of the Ignatian writings are in Cautelier's *Patres Aevi Apostolici* (2 vols., Paris, 1672; 2d and more complete ed., Amsterdam, 1724), those by Jacobson (Oxford, 1838) and Petermann (Leipsic, 1849), and Cureton's *Corpus Ignatianum* (London, 1849).

IGNATIUS, Saint, patriarch of Constantinople, born about 798, died Oct. 23, 878. He was the youngest son of the emperor Michael I., and his original name was Nicetas; but on the deposition of his father by Leo the Armenian, he was made a eunuch by Leo and entered a monastery, assuming the name of Ignatius. He was raised to the patriarchate in 846. He was an enemy of the iconoclasts, and would not suffer Gregorius Asbestus, bishop of Syracuse, to be present at his consecration, because of his heterodoxy. In 857 he refused to admit Bardas, brother of the empress Theodora, as a communicant, on account of his reported immorality, whereupon the offender caused him to be deposed, and Photius to be elected patri-

arch in his place. After his deposition he was treated with the greatest cruelty, and banished to Mitylene; but when Basil the Macedonian ascended the throne in 867, he was recalled.

IGNATIUS BEAN. See STRYCHNIA.

IGNIS FATUUS, a flickering light seen at night over the surface of marshy grounds or graveyards. Sometimes it moves quietly along, resembling the light of a lantern carried in the hand; and again it appears not alone, but two or three together dancing merrily together up and down. In the night mists it seems like the light from some neighboring house; and many a traveller has been led by it into dangerous bogs, from which he found no escape till the appearance of the morning light. It is not strange that a character of mystery should have attached to this luminous appearance, and that the ignorant should have ascribed it to some evil spirit. They called it "Will o' the wisp" and "Jack with a lantern," and this imaginary person is often alluded to by the old English poets. It is commonly believed that the light retires before one who pursues it; this notion is confirmed by the statements of some observers, and disproved by those of others. In Milner's "Gallery of Nature," p. 544, is recorded a statement of Mr. Blesson, who carefully investigated the phenomena in the forest of Gorbitz, in Brandenburg. On a marshy spot he observed bluish purple flames at night, where bubbles of air issued during the day. These flames retired as he approached, in consequence, he supposed, of the air being agitated by his movement. When he stood perfectly still they soon appeared within reach; and then, carefully guarding against disturbing the air by his breath, he succeeded in singeing a piece of paper, which became covered with a viscous moisture. At last a narrow slip of paper took fire. By disturbing the air over the spot he caused the flames to disappear entirely, but in a few minutes after quiet was restored they appeared again over the air bubbles, apparently without having communication with any known source of flame. On suddenly introducing a torch after extinguishing the flame, a kind of explosion was heard, and a red light was seen over 8 or 9 sq. ft. of the marsh, which diminished to a small blue flame from 2½ to 3 ft. high. He concluded that the cause of the ignis fatuus was the evolution of inflammable gas from the marsh, and that the flames existed by day as well as at night, though not then visible. The lights seen occasionally over churchyards are of similar appearance to those described. These meteors are supposed to be the result of the spontaneous combustion of inflammable gases generated by the decomposition of vegetable or animal bodies. Phosphuretted hydrogen, it is well known, bursts into flame as it is allowed to escape into the air from the vessels in which it is prepared. It is produced by the decay of animal matters, and, if thinly diffused here and there over the surface of a marsh, may present the changing,

flickering light of the ignis fatuus, as difficult to locate as the illumination of the fireflies, for which it has been mistaken by several eminent naturalists. What is known as marsh gas is a highly inflammable carburetted hydrogen, which bubbles up through the water that covers boggy places, and may be inflamed on the surface. This may be ignited by phosphuretted hydrogen, and add to the extent and permanence of the flames. The small quantity of these combustible matters present in the air will account for the feebleness of the flames, which have rarely been known to set fire to other substances; and the varying quantity and purity of that exhaled would explain the constantly shifting brightness of the light. According to the account in the "Gallery of Nature" referred to, in the middle of the last century the snow on the summit of the Apennines appeared enveloped in flame; and in the winter of 1693 hay ricks in Wales were set on fire by burning gaseous exhalations.

IGUALADA, a town of Spain, in the province and 33 m. N. W. of the city of Barcelona; pop. about 11,500. It stands on high ground, on the left bank of the river Noya. The streets are narrow, and the buildings packed closely together, with little regard to elegance, comfort, or cleanliness. Woollen and cotton goods, paper, and firearms are manufactured, and there are fairs in January and August.

IGUANA, a lizard constituting the type of the family *iguaniide*. The family characters are: a body covered with horny scales, without bony plates or tubercles, not disposed in circular imbricated series, and without large square plates on the abdomen; there is generally a crest along the back or the tail; no large polygonal scutes on the head; the teeth sometimes in a common alveolus, and sometimes united to the free edge of the jaws; tongue thick, free only at the point, and without sheath; eyes with movable lids; toes distinct, free, and all unguiculated. The very numerous genera of this family have been conveniently divided into two subfamilies by Duméril and Bibron, according to the manner in which the teeth are implanted. In the pleurodonts, all but one American, the teeth are arranged in a groove of the jaws, are attached to their inner surface, and are often curiously flattened and serrated on the free edge; in the acrodonts, all of the eastern hemisphere, there is no such groove, and the teeth grow upon the edge of the jaws. For the characters of the second subfamily, having 15 genera and about 60 species, see DRAGON, STELLIO, and the genus *agama*, below. The pleurodonts comprise 31 genera and more than 100 species; *anolis* and *basiliscus* have been already noticed under those titles, and the only genus here described will be *iguana* (Laurenti). The characters of this genus are: a very large thin dewlap under the throat; cephalic plates flat, unequal, and irregular; a double row of small palate teeth; a crest on the back and tail; fingers and toes five, long,

of unequal lengths, the fourth of the hind foot very long; a single row of femoral pores; tail very long, slender, compressed, and covered with small, regular, imbricated, ridged scales. The common iguana (*I. tuberculata*, Laur.) attains a length of 4 or 5 ft., of which the tail is about two thirds; it is found in tropical South America and the West Indies. The nasal openings are at the end of the obtuse muzzle; the teeth are about 50 in each jaw, with card-like ones on the palate in two series; the dewlap is about as deep as the head, triangular, having about a dozen serrations on its anterior border; along the neck and back is a comb-like crest of about 55 scales, highest in this species, extending on to the tail, where it becomes a simple serrated ridge; the femoral pores are 14 or 15, widest and opening in a single scale in the males. The color above is greenish, with bluish and slaty tints, and greenish yellow below; on the sides are generally brown zigzag bands

Iguana tuberculata.

with a yellow border, with a yellowish band on the front of the shoulder; some are dotted with brown, with yellow spots on the limbs; the tail is ringed broadly with alternate brown and yellowish green. The flesh of the iguana is considered a great delicacy, though it is not peculiarly wholesome. It passes most of its time in trees, in which it is caught by slip nooses; it is said to be a good swimmer, and some of the subfamily, as *amblyrhynchus*, pass most of their time in the water, and even in the sea.—The iguanas of the eastern hemisphere, of the acrodont subfamily, are often called agamas, from one of the principal genera. The genus *agama* (Daudin) has a flat triangular head, neck, and sometimes the ears spiny, body covered with small imbricated scales, no dorsal crest, tail long, slender, and rounded, anal but no femoral pores, a longitudinal fold along the throat, and sometimes a transverse one; the teeth are united to the edge of the jaw, and may be distinguished into posterior or molars

and anterior or canines and incisors; no teeth on the palate. None of this subfamily are found in America. The common agama (*A. colonorum*, Daudin) is the largest of the genus, being from 12 to 16 in. long, of which the tail is more than half; it is found on the Guinea and

Agama colonorum.

Senegal coasts. The spiny agama (*A. spinosa*, Seba) is short and thick, with short tail and spiny scales; it is about 7 in. long, and inhabits the Cape of Good Hope. Some of the acrodonts in Asia and Australia are of very strange forms; the habits and general appearance are like those of the American iguanas.

IGUANODON, a gigantic fossil saurian reptile, discovered by Dr. Mantell in the Wealden formation of Great Britain in 1822, and so named from the teeth resembling in shape those of the iguana. The teeth of the iguanodon resemble those of the iguana also in the elongation and contraction of the base, the expansion

Iguanodon.

of the crown, the serration of the edges, and the thin coating of enamel; but the crown is relatively thicker, with a more complicated external and internal structure, and the roots are placed in separate sockets as in the crocodile. The vertebræ have slightly concave articular

surfaces on the body, with nearly flat sides; the neural arch of the dorsals is high and expanded, as in other dinosaurians; the antero-posterior diameter is from 4 to 4½ in.; the spinal canal is completely enclosed by the neural arches; the sacral region is of considerable extent, and widely embraced by the iliac bones; in the tail the spinous processes increase for some distance below the sacrum and then diminish, and this organ was probably relatively shorter than in the iguana; the ribs are largely developed in the thoracic and abdominal regions, and connected both with the body and the transverse process of each vertebra, as in other dinosaurians and in crocodiles, and unlike the iguana and other lizards; the scapular arch is intermediate between the crocodilian and lizard type, the clavicle being more than 3 ft. long; the pelvic arch has rather a lacertian character; the thigh bones are stout, and about 3 ft. long, with the head rounded and produced, as in mammals, over the inner side of the shaft, and a singularly flattened trochanter, and must have supported the heavy body in a manner like that of the large pachyderms; the bones of the leg are robust and about 2½ ft. long, and the whole extremity bears little resemblance to that of the iguana; the feet resemble those of saurians. This reptile has been estimated by Owen as about 28 ft. in length, of which the head was 3 and the tail 13 ft.; it stood higher on the legs than any existing saurian, and was terrestrial in its habits; the worn condition of the teeth indicates that it was a herbivorous animal. It belongs to the family of dinosaurians with *megalosaurus*, *hyleosaurus*, and *pelorosaurus*, and is found in the Wealden and cretaceous formations. The *I. Mantelli* (Cuv.), from the characters of the worn dental surfaces, must have performed a true process of mastication, and the glenoid cavity must have permitted a lateral movement of the lower jaw; the large facial foramina indicate more fleshy cheeks and lips than in any existing saurians. Dr. Mantell was of opinion that it had a nasal integumental horn.

IHRE, Johan, a Swedish philologist, born in Lund, March 3, 1707, died Dec. 1, 1780. His father, of Scotch descent, was for a time professor of theology at Upsal. He graduated at the university in 1730, and in 1738 became professor of belles-lettres and political science. His *Glossarium Sueco-Gothicum* (2 vols., Upsal, 1769) was prepared under the patronage of the government, which allowed him in 1756 a grant of 10,000 Swedish dollars. His dissertations on the Eddas and on Ulfilas are important.

ILI, or **Eelce**, a river of central Asia, which rises on the northern slope of the mountains of Thian-shan-nan-lu, traverses a part of eastern Turkistan, and flows into Lake Tengiz or Balkash, near the borders of Siberia. Its length is about 450 m.

ILIAD. See HOMER.

ILINIZA, **Ilinissa**, or **Illinissa**, Pyramids of, certain peaks of the Cordilleras of Quito, in South

America; about 10 m. S. of Quito. They are about 17,380 ft. high, and seem originally to have constituted a single mountain, which has been rent apart by volcanic forces. They are visible not only from all parts of the country intervening between the Cordilleras of Quito and the Pacific, but from great distances at sea.

ILION, a village in the town of German Flats, Herkimer co., New York, on the right bank of the Mohawk river, and on the New York Central railroad and Erie canal, 70 m. W. N. W. of Albany; pop. in 1870, 2,876. It contains two hotels, a national bank, a brewery, a weekly newspaper, and several schools and churches. It is chiefly noted as the seat of E. Remington and sons' firearms manufactory, of the Remington empire sewing-machine company, and the Remington agricultural works, which employ a large number of men. It was incorporated in 1865.

ILISSUS, a river of Attica, rising near the N. extremity of Mt. Hymettus, and flowing through the S. part of Athens toward the Phaleric bay, which it rarely reaches even in the rainy season, while in summer it always dries up in the vicinity of the city. The spreading plane trees and verdant banks of the Ilissus, which Plato immortalized in his "Phædrus," have given place to pigmy bushes and sunburnt rocks.

ILIUM. See Troy.

ILİYATS, or **Eelants**, a nomadic tribe of Persia, Kkiva, and Turkistan. The name Iliyat is the plural of *iel* (*eel*), a tribe, equivalent to the Arabic *kabilah*. The Iliyats are mostly of Turkish, Arabic, and Kurdish descent, and form an important portion of the population of Persia and adjacent countries; their actual numbers are not known, but it is said that the Iliyat tribes tributary to Khiva numbered 195,000. They live in tents and have no settled habitations, changing their places of encampment with the season or climate. Some tribes live solely by rapine and plunder; others resort only occasionally to such means. They have large flocks and herds, which they often augment by taking those of their neighbors; they are therefore much dreaded by the settled and civilized population. The distances that some of the Iliyat tribes travel in their annual migrations are wonderful. From the southern shores of Fars, the Kashkai tribe of Iliyats arrive in spring on the grazing grounds of Ispahan, where they are met by the Bakhtiars from the northern shores of the Persian gulf. At the approach of winter both tribes return. The Iliyats are Mohammedans of the Sunni sect, but are not very strict in their religious observances, and are not ruled like the townsmen by the mollah. In each province of Persia there are two chiefs acknowledged by all the tribes. The chief of the Kashkai tribe, which numbers more than 25,000 tents, is obliged by the government to reside at Shiraz, as a hostage for the good behavior of his clan, though otherwise free to live as he pleases.

The Iliyat women are said to be chaste, and many of the best families in Persia are of Iliyat origin. The present royal family is of the Kajar tribe, a Turkish *iel*, which came into Persia with Tamerlane.—See Mounsey's "Journey through the Caucasus and the Interior of Persia" (London, 1872), and Markham's "History of Persia" (London, 1874).

ILKESTON, a town of Derbyshire, England, 9 m. N. E. of Derby, on the Erwash Valley railway; pop. in 1871, 9,662. It is rapidly increasing in population, and contains a fine old parish church and a mechanics' institute and library. Hosiery and silk fabrics are manufactured, and coal is mined.

ILLE-ET-VILAINE, a N. W. department of France, in Brittany, bounded N. by the English channel, and bordering on the departments of Manche, Mayenne, Loire-Inférieure, Morbihan, and Côtes-du-Nord; area, 2,596 sq. m.; pop. in 1872, 589,532. It is named after its principal rivers, the Ille and Vilaine, the latter flowing W. and S. W. through this department and Morbihan to the Atlantic, and partly navigable, and the former joining it from the north at Rennes. It is traversed from W. to E. by the Armoric hills or Menez mountains. The surface is irregular, and the soil generally poor. Flax and hemp are extensively cultivated; tobacco is grown to some extent, as are grapes and other fruit. The fisheries are important, and excellent oysters are found in the bay of Cancale. Several iron mines are worked; slate, quartz, limestone, and granite are quarried; lead and copper ore are found; mineral springs are numerous. The manufactures consist chiefly of coarse linen and sail cloth. The coasting trade is active. It is one of the poorest French departments. It is divided into the arrondissements of Rennes, Fougères, Montfort, St. Malo, Vitré, and Redon. The principal seaport is St. Malo. Capital, Rennes.

ILLINOIS, a tribe of North American Indians, of the Algonquin family, comprising the Peorias, Moingwenas, Kaskaskias, Tamaroas, and Cahokias. At an early period, aided perhaps by the Delawares on the east, they drove the Quapaws, a Dakota tribe whom they styled Arkansas, from the Ohio to the southern Mississippi. About 1640 they nearly exterminated the Winnebagoes. They were at war with the Iroquois from about 1656, and with the Sioux soon after. The French, by their missionaries, first met the Illinois at Chegoimegon on Lake Superior in 1667; in 1672 Marquette found the Peorias and Moingwenas in three towns west of the Mississippi, near the Des Moines, as well as Peorias and Kaskaskias on the Illinois. The Tamaroas were on the Mississippi, and a tribe called the Michigameas, who seem to have been really Quapaws, also belonged to the confederacy. The Illinois at this time were numerous and brave, expert bowmen, but not canoe men. They moved off to the plains beyond the Mississippi in villages for a short summer hunt, and for a winter hunt of

four or five months. Then they would gather in a large town, of arbor-like cabins covered with double water-proof mats, with generally four fires to a cabin, and two families to a fire. Allouez, Membré, and other missionaries found the chief Illinois town consisting of 300 to 400 cabins and 8,000 people. They were badly defeated by the Iroquois in 1679, shortly after La Salle reached there, and in the war lost 300 or 400 killed and 900 prisoners; but they recovered and aided the French in their operations against the Iroquois, sending their contingent to the expeditions of De la Barre and Denonville. Although constantly at war and greatly addicted to vices, they listened to the French missionaries Marquette, Allouez, Gravier, and others, who finally converted them all, and greatly improved their condition. In 1700 Chicago, their great chief, visited France, and was highly esteemed. His son of the same name retained the great influence of his father till his death in 1754. In 1700 the Kaskaskias removed from the upper waters of the Illinois to the spot that bears their name, led by their chief Roinsac, who wished to emigrate to Louisiana. In 1712 they marched to Detroit to relieve that post, then besieged by the Foxes. In the war with that tribe they suffered severely, and the Illinois of the Rock and of Pimiteouy were driven from their villages. In 1719 the whole nation was reduced to 3,000 souls. They remained faithful to the French in the Natchez troubles, and sent a force on D'Artaguettes fatal expedition against the Chickasaws. Although they lost constantly in their war with the Foxes, their head chief Papapé Changouhias led a force with Villiers against some of the frontier posts in Virginia in April, 1756, and captured a small fort. They took no part in Pontiac's war; but when that chieftain was killed in one of their towns, the Foxes renewed the war. They joined the Miamis in their war against the United States, but made peace at Greenville, Aug. 3, 1795. By act of March 3, 1791, 350 acres were secured to the Kaskaskias, and the right of locating 1,280 acres in addition. Gen. Harrison in 1803 negotiated a treaty at Vincennes, in which their decline was recited, an annuity of \$1,000 given, and provision made for building a house for the chief and a Catholic church, as well as for the maintenance of a priest. The Peorias, who were not parties to this treaty, joined in that of Edwardsville, Sept. 25, 1818, by which the Illinois ceded all their lands in the state for \$2,000 in goods and a 12 years' annuity of \$300. The Peorias, to the number of 100, were on Blackwater river, Missouri, and 36 Kaskaskias remained in Illinois. By the treaty of October, 1832, they again ceded lands, receiving a large tract further west, with some cash and an outlay for erecting dwellings and supplying agricultural implements. They were placed within the limits of the present state of Kansas, where they remained till 1867. They seemed to improve, but lost in numbers, so

that in 1854 they confederated with the Weas and Piankeshaws. In 1867 they were again removed, and placed southwest of the Quapaws, on a reservation of 72,000 acres. Here they remain, but the whole Illinois nation had dwindled in 1872 to some 40 souls; the combined tribe of Weas, Piankeshaws, Peorias, and Kaskaskias numbering only 160 in all. The United States government in 1873 held stocks for their benefit amounting to \$124,747 94, and a balance at interest of \$64,164 69. The language of the Illinois was reduced to grammatical rules by Père Gravier, and Père le Boulanger drew up a very full grammar and dictionary.

ILLINOIS, one of the interior states of the American Union, the eighth admitted under the federal constitution, and now the fourth in population. It is situated between lat. 36° 59' and 42° 30' N., and lon. 87° 35' and 91° 40' W.; extreme length N. and S. 385 m., extreme breadth E. and W. 218 m.; area, 55,410 sq. m. It is bounded N. by Wisconsin, N. E. by Lake

State Seal of Illinois.

Michigan, E. by Indiana, from which it is separated in part by the Wabash river, S. E. and S. by Kentucky, from which it is separated by the Ohio, and S. W. and W. by Missouri and Iowa, from which it is separated by the Mississippi. The state is divided into 102 counties, viz.: Adams, Alexander, Bond, Boone, Brown, Bureau, Calhoun, Carroll, Cass, Champaign, Christian, Clark, Clay, Clinton, Coles, Cook, Crawford, Cumberland, De Kalb, De Witt, Douglas, Du Page, Edgar, Edwards, Effingham, Fayette, Ford, Franklin, Fulton, Gallatin, Greene, Grundy, Hamilton, Hancock, Hardin, Henderson, Henry, Iroquois, Jackson, Jasper, Jefferson, Jersey, Jo Daviess, Johnson, Kane, Kankakee, Kendall, Knox, Lake, La Salle, Lawrence, Lee, Livingston, Logan, McDonough, McHenry, McLean, Macon, Macoupin, Madison, Marion, Marshall, Mason, Massac, Menard, Mercer, Monroe, Montgomery, Morgan, Moultrie, Ogle, Peoria, Perry, Piatt, Pike, Pope, Pulaski, Putnam, Randolph, Richland, Rock Island, St. Clair, Saline, Sangamon, Schuyler, Scott, Shelby, Stark, Stephenson, Tazewell, Union, Vermilion, Wabash, War-

ren, Washington, Wayne, White, Whitesides, Will, Williamson, Winnebago, and Woodford. Springfield, near the geographical centre of the state, lat. 39° 48' N., lon. 89° 45' W., is the seat of government; it is situated in the midst of a fine agricultural district, and has an active trade, being well supplied with railroad transportation. Chicago is the commercial metropolis, and the largest city on the northern lakes. Kaskaskia and Cahokia are the oldest towns in Illinois, having been founded by the French some time between 1680 and 1690. Kaskaskia was the first capital, and so remained till 1818, when the government was removed to Vandalia, and thence to Springfield in 1836. According to the census of 1870, the cities of Illinois were: Alton, pop. 8,665; Amboy, 2,825; Anna, 1,269; Aurora, 11,162; Belleville, 8,146; Bloomington, 14,590; Bushnell, 2,003; Cairo, 6,267; Centralia, 3,190; Champaign, 4,625; Chicago, 298,977; Danville, 4,751; Decatur, 7,161; Dixon, 4,055; Elgin, 5,441; El Paso, 1,564; Freeport, 7,889; Galena, 7,019; Galesburg, 10,158; Jacksonville, 9,203; Joliet, 7,263; La Salle, 5,200; Litchfield, 3,852; Macomb, 2,748; Mendota, 3,546; Monmouth, 4,662; Morris, 3,138; Mount Carmel, 1,640; Olney, 2,860; Ottawa, 7,736; Pekin, 5,696; Peoria, 22,849; Peru, 3,650; Quincy, 24,052; Rockford, 11,049; Rock Island, 7,890; Shelbyville, 2,051; Springfield, 17,364; Sterling, 3,998; Watseka, 1,551; and Waukegan, 4,507. The population of Illinois has been as follows:

CENSUS YEARS.	White.	Free colored.	Slaves.	Total.	Rank.
1810.....	11,501	618	168	12,282	28
1820.....	53,788	457	917	55,211	24
1830.....	155,061	1,637	747	157,445	20
1840.....	472,254	3,593	331	476,183	14
1850.....	846,084	5,436	851,470	11
1860.....	1,704,291	7,623	1,711,951	4
1870.....	2,511,096	23,762	2,539,891	4

Of the total population in 1870, 1,316,537 were males and 1,223,354 females; 2,024,693 were of native and 515,198 of foreign birth. Of the former, 1,189,503 were born in the state; of the foreigners, 32,550 were born in British America, 3,711 in Denmark, 10,911 in France, 203,758 in Germany, 53,871 in England, 120,162 in Ireland, 15,737 in Scotland, 3,146 in Wales, 4,180 in Holland, 11,880 in Norway, 29,979 in Sweden, and 8,980 in Switzerland. The density of population was 45.84 to the square mile. There were 474,533 families, with an average of 5.35 persons to each, and 464,155 dwellings, with an average of 5.47 persons to each. The increase of population from 1860 to 1870 was 48.36 per cent. The number of male citizens 21 years old and upward was 542,833. There were in the state 818,766 persons from 5 to 18 years of age; the number that attended school was 548,225; 86,363, 10 years of age and over, could not read, and 133,584 could not write. Of the latter, 90,595 were of native and 42,989 of foreign birth;

54,671 were white males, and 69,053 white females; 4,924 were colored males, and 5,024 colored females; 12,525 were from 10 to 15 years old, 15,340 from 15 to 21, and 105,709 21 and over, of whom 40,081 were white males, 56,857 white females, 3,969 colored males, and 4,082 colored females. The proportion of illiterates 10 years of age and upward to the total population of the same age was 7.38 per cent., being 6.29 for males and 8.59 for females. The proportion of illiteracy among adults was 7.16 per cent. for males and 11.16 for females. The number of persons supported by public charity during the year ending June 1, 1870, was 6,054, at a cost of \$556,061; there were receiving support June 1, 1870, 2,363, of whom 1,254 were native and 1,109 foreign born. The number of persons convicted of crime during the year was 1,552. Of the total number (1,795) in prison June 1, 1870, 1,372 were native born and 423 foreigners. There were 1,042 blind, 833 deaf and dumb, 1,625 insane, and 1,244 idiotic. Of the total population 10 years old and over (1,809,606), there were engaged in all occupations 742,015; in agriculture, 376,441, including 133,649 agricultural laborers, 240,256 farmers and planters, and 2,162 gardeners and nurserymen; in professional and personal services, 151,931, of whom 3,192 were clergymen, 44,903 domestic servants, 431 journalists, 63,130 laborers not specified, 2,683 lawyers, 4,861 physicians and surgeons, 8,869 teachers not specified; in trade and transportation, 80,422; and in manufactures and mechanical and mining industries, 133,221, of whom 9,412 were blacksmiths, 6,279 boot and shoe makers, and 23,040 carpenters and joiners. The total number of deaths from all causes, as reported by the census of 1870, was 33,672, the percentage of deaths to the population being 1.33; from consumption, 3,641, there being 9.2 deaths from all causes to 1 from consumption. There were 2,882 deaths from pneumonia, 2,162 from scarlet fever, 888 from intermittent and remittent fevers, and 2,551 from diarrhoea, dysentery, and enteritis.—Illinois occupies the lower part of that inclined plane of which Lake Michigan and both its shores are the higher sections. Down this plane in a very nearly S. W. direction the principal rivers have their courses to the Mississippi. The lowest section of this plane is also the extreme S. angle of the state, and is only 340 ft. above the gulf of Mexico. The greatest elevation of the country is 1,150 ft., and the mean elevation about 550 ft., above tide water. Next to Louisiana and Delaware, indeed, Illinois is the most level state of the Union. A small tract in the N. W. corner of the state around Galena, which includes the lead mines, is hilly and somewhat broken, and there are bluffs on the Mississippi and Illinois rivers; but by far the greater portion of the surface consists of vast level or gently undulating prairies. A low mountain ridge extends across the S. end of the state, from Grand Tower on the Mississippi to Shawneetown

on the Ohio, constituting the fruit region of southern Illinois. The chief rivers within the state are the Rock, Illinois, and Kaskaskia, affluents of the Mississippi; the Embarras and Little Wabash, tributaries of the Wabash; and the Saline and Cash, which fall into the Ohio. The Illinois is much the largest of these; its constituents are the Kankakee from Indiana and the Des Plaines from Wisconsin, and in its entire course of nearly 500 m. (245 navigable) to the Mississippi it receives the Fox and Spoon rivers and Crooked creek from the right, and the Vermilion, Mackinaw, Sangamon, &c., from the left. It has a wide deep bed, and in some parts opens into broad and lake-like expanses. Rock river also rises in Wisconsin, and has a course of 300 m. to the Mississippi; it is imperfectly navigable for 75 m., and its upper course is impeded by rapids. The Kaskaskia has its sources in Champaign co. (in which also rise the Sangamon, Embarras, and the southern constituents of the Vermilion), and pursues a direction nearly parallel with the Illinois; it has a length of 250 m. The Big Muddy, an affluent of the Mississippi, between the Ohio and the Kaskaskia, is also a considerable stream. The rivers flowing into the Ohio and Wabash are generally of less volume than the smaller class of streams flowing into the Mississippi, but several are navigable. Chicago river falls into Lake Michigan; it is formed by the union of its N. and S. branches about 1 m. from the lake. Both branches are deep (12 to 15 ft.), and in connection with the main river form a spacious harbor, which has been much improved by the extension of piers far into the lake. The S. branch is connected with the navigable Illinois at Peru by the Illinois and Michigan canal, 96 m. long.—Notwithstanding the general uniformity of the surface, Illinois is not destitute of interesting scenery. The river bluffs contrast strikingly with the smooth prairies. The most remarkable of these elevations are on the Mississippi, and are from 100 to 400 ft. high. Fountain bluff in Jackson co. is oval, 6 m. in circuit and 300 ft. high; the top is full of sink holes. Starved Rock and Lover's Leap are eminences on the Illinois; the first named is a perpendicular mass of limestone and sandstone, 8 m. below Ottawa, rising 156 ft. above the river, and the latter a ledge of precipitous rocks some distance above Starved Rock. Nearly opposite Lover's Leap is Buffalo Rock, 60 ft. high, precipitous toward the river, but sloping inland. The Cave in the Rock, in Hardin co., on the Ohio, presents on approach a vast mass of rocks, some resembling castellated ruins, and others jutting out in a variety of forms. The entrance to the cave, which is little above high water, is a semicircular hole 80 ft. wide and 25 ft. high, and the cave so far as explored consists of a chamber 80 ft. long, at the end of which is a small opening which probably leads into a second chamber. In the earlier days of

settlement it was the abode of bands of robbers and river pirates.—The unbroken surface of Illinois affords a drainage extending from the borders of Lake Michigan toward the west and southwest across the entire state. The post-tertiary clay and sands containing freshwater shells of living species, found a few feet above the level of the lake, and forming its banks, indicate that at no remote geological period the land was somewhat less elevated than at present; and the valley of the Illinois with its strongly marked terraced walls of limestone, so disproportioned to the small river that flows between them, would seem to owe its origin to mightier currents, and to point to a time when the great lakes found an outlet by this way to the Mississippi and the gulf of Mexico. The state has been described and mapped as one great coal field; but as the arrangement of the strata has been more carefully studied, this statement is to be received with some modifications. Still, the prevailing rocks throughout the state are those of the coal measures. They occupy most of the country lying S. of a line traced from the mouth of Rock river E. to La Salle co., and thence S. E., crossing the line of Indiana. The formation covers a large portion of the W. part of Indiana, and stretches S. into Kentucky. Its W. margin is near the Mississippi river, along which a belt of the underlying carboniferous limestone comes up, and cuts off the coal formation on that side. The included area, reckoned as one coal field, covers about 40,400 sq. m., of which 30,000 are in Illinois. The most important veins are from 6 to 8 ft. thick. (See COAL, vol. iv., p. 738.) The importance of the coal beds in Illinois is greatly enhanced by their position, conveniently near the Mississippi or the Ohio, and to the railroads, which traverse the state from N. to S. and from E. to W.; and more than 2,000,000 tons per annum are now mined in the state. The iron ores found in the coal measures are of little value. The N. W. corner of Illinois includes a portion of the great western lead-bearing belt. Though in Illinois but a small district, comprising part of Jo Daviess co., contains the lower Silurian limestones in which the lead ores are found, the mines have proved so productive that the metal ranks as one of the important products of the state. Salt is chiefly a product of the southern section, and is found in springs about the head waters of Big Muddy river, Saline creek, and the Little Wabash. Sulphurous and chalybeate springs exist in several localities.—The soils of Illinois are of diluvial origin, and it is probable that in the early geological ages the whole state was a portion of the bed of a great lake. The prairie soils are deep, fertile, and rockless, and produce a luxuriant growth of native grasses and vegetation, which formerly sustained countless herds of buffaloes. The largest of the prairies is that between the streams flowing into the Wabash and those which enter the Mississippi. This

is called the Grand Prairie, but is properly a combination of small prairies partially separated by tracts or groves of timber. The barrens, or oak openings, as they are here called, have frequently a thin soil. In the bottoms or alluvial borders of the rivers the soil is chiefly formed from the deposits of the waters during floods. In some cases the mould so formed is more than 25 ft. deep, and of inexhaustible fertility. One fifth of the alluvial land, however, is unfit for present cultivation, but is productive of timber. A tract called the American bottom, extending along the Mississippi for 90 m., and about 5 m. in average breadth, is of this formation. About the French towns it has been cultivated and produced Indian corn every year without being manured for nearly two centuries. In every part of the state the plough may pass over thousands of acres without meeting even so much as a pebble to impede its course.—The native animals are now almost extinct, but Illinois still has abundance of game, and its northern rivers abound in trout and other fish. The kinds of timber most abundant are oak, black walnut, ash, elm, sugar maple, locust, linden, hickory, pecan, and persimmon. In the south and east yellow poplar and beech are the peculiar growths, and near the Ohio are clumps of a yellow pine and cedar. The bottoms produce cottonwood, sycamore, &c. Illinois indeed is abundantly supplied with timber, but it is unequally distributed, and immense tracts are entirely bare. The fruit trees embrace the apple, peach, cherry, plum, &c., and the grape is largely cultivated. The prevailing winds are N. and N. W. and S. and S. W., the former in the winter months, and the latter during the remainder of the year. The evenness of the surface allows of their free passage, and the atmosphere is in constant motion. Hence the winters are excessively cold, and the summers more than usually hot. The summer heat, however, is greatly modified and refreshed by the ever present breezes; and on the whole the climate is favorable for outdoor occupations, the proportion of clear and cloudy days being about 245 of the former to 120 of the latter. The mean annual temperature on the 40th parallel is about 54°, that of summer 77° and that of winter 33½° F. These figures, however, will vary considerably N. and S. of the parallel indicated; at Beloit on the N. line the mean temperature is 47½°, and at Cairo, the S. angle of the state, 58½°. Vegetation begins with April, and the first killing frosts occur near the end of September. The general salubrity of the climate is well attested; but fevers and fluxes are frequently prevalent in the river bottoms and in the swamps which cover a large part of the southern section. The upland prairies are almost free from endemic disorders.—Illinois is in the front rank of agricultural states. According to the census of 1870, it contained more acres of improved land, and produced more wheat, Indian corn,

and oats, than any other state. In the production of barley it ranked next to California and New York; of flax, next to Ohio and New York; of rye, next to Pennsylvania and New York; and of wool, next to Ohio, California, New York, Michigan, and Pennsylvania. In the value of all live stock on farms it was surpassed only by New York, and contained more swine and horses than any other state, more milch cows than any other except New York, Pennsylvania, and Ohio, and more sheep than any other except Ohio, California, New York, Michigan, Pennsylvania, and Indiana. The state contained 10,329,952 acres of improved land, 5,061,578 of woodland, and 1,491,331 of other unimproved land. The total number of farms was 202,803, including 53,240 having from 20 to 50 acres, 68,130 from 50 to 100, 65,940 from 100 to 500, 1,367 from 500 to 1,000, and 302 containing 1,000 acres and over. The cash value of farms was \$920,506,346; of farming implements and machinery, \$35,576,587; total amount of wages paid during the year, including value of board, \$22,338,767; total estimated value of all farm productions, including betterments and additions to stock, \$210,860,585; orchard products, \$3,571,789; produce of market gardens, \$765,992; forest products, \$1,087,144; home manufactures, \$1,408,015; animals slaughtered or sold for slaughter, \$56,718,944; value of all live stock, \$149,756,698. There were 853,738 horses, 85,075 mules and asses, 640,321 milch cows, 19,766 working oxen, 1,055,499 other cattle, 1,568,286 sheep, and 2,703,343 swine. The chief productions were: 10,133,207 bushels of spring and 19,995,198 of winter wheat, 2,456,578 of rye, 129,921,395 of Indian corn, 42,780,851 of oats, 2,480,400 of barley, 168,862 of buckwheat, 115,854 of peas and beans, 10,944,790 of Irish and 322,641 of sweet potatoes, 10,486 lbs. of clover seed, 153,464 of grass seed, 280,043 of flax seed, 2,747,339 tons of hay, 465 bales of cotton, 5,249,274 lbs. of tobacco, 5,739,249 of wool, 36,083,405 of butter, 1,161,103, of cheese, 104,032 of hops, 2,204,406 of flax, 136,873 of maple sugar, 1,547,178 of honey, 146,262 of wax, 1,960,473 gallons of sorghum molasses, 10,378 of maple molasses, 111,882 of wine, and 9,258,545 of milk sold. In 1872 there were 2,093,308 acres of wheat under cultivation; Indian corn, 7,087,040; oats, 1,817,463; meadows, 2,178,237; other field products, 886,166; in enclosed pasture, 3,807,082; in orchard, 320,702; and in woodland, 6,289,236. There were 930,947 horses, assessed at \$48,790,933; 2,014,801 cattle, \$35,742,563; 98,316 mules and asses, \$5,809,494; 1,092,080 sheep, \$2,140,474; hogs, 3,560,083, \$11,285,464.—In manufacturing industry, Illinois is also classed among the first states of the Union. According to the census of 1870 it ranked sixth both in the amount of capital invested in manufactures and in the value of products. In the total amount of capital it was surpassed by Pennsylvania, New York, Massa-

chusetts, Ohio, and Connecticut; in the value of products by New York, Pennsylvania, Massachusetts, Ohio, and Missouri. In the value of the products of butchering, distilled liquors, planed lumber, and pork packed, Illinois ranked first. The relation of the state to the United States in these industries is shown in the following statement of the total value of products:

INDUSTRIES.	United States.	Illinois.
Butchering	\$13,686,061	\$4,251,712
Liquors, distilled.....	36,191,133	7,888,751
Lumber, planed.....	42,179,702	7,290,465
Pork, packed.....	56,429,331	19,818,851

In the production of grease and tallow Illinois ranks next to New York; in agricultural implements, next to Ohio and New York; in carriages and wagons, next to New York and Pennsylvania; in oil, next to Missouri and Ohio; in saddlery and harness, next to Missouri, New York, and Pennsylvania; in sash, doors, and blinds, next to New York, Pennsylvania, Ohio, and Missouri; in men's clothing, next to New York, Pennsylvania, Massachusetts and Ohio. From the above table it appears that more than one third in value of all the pork packed in the United States in 1870 was contributed by Illinois. Formerly the supremacy in this respect was held by Ohio, in consequence of the magnitude of this industry in Cincinnati; but since 1862-'3 that supremacy has been held by Chicago. According to a careful report prepared for the Cincinnati chamber of commerce by Sidney D. Maxwell, the number of hogs packed in the southern and western states from Nov. 1, 1873, to

March 1, 1874, was 5,383,810, the aggregate gross weight of which was 1,444,311,304 lbs.; of these, 1,870,855, weighing in the aggregate 511,867,475 lbs., were packed in Illinois. The aggregate cost of the hogs was \$22,694,399, and the total product of lard 69,808,163 lbs. The chief centres of this industry for two years are shown in the following statement:

PLACES WHERE PACKED.	NUMBER OF HOGS PACKED.	
	1872-'3.	1873-'4.
Barry	9,607	11,000
Charleston	10,200	11,866
Chicago	1,425,079	1,520,024
Galena	29,000	26,000
Lacon	17,091	10,327
Mattoon	4,988	16,451
Pekin	6,000	12,000
Peoria	102,500	68,150
Quincy.....	51,983	54,293
Total	1,884,218	1,870,855

The growth of this industry in Illinois has been very rapid; thus the number of hogs packed was 805,843 in 1868-'9, 862,412 in 1869-'70, 1,240,959 in 1870-'71, and 1,631,026 in 1871-'2. The total number of manufacturing establishments reported by the census of 1870 was 12,597, using 2,330 steam engines of 73,091 horse power, and 528 water wheels of 12,593 horse power, and employing 82,979 hands, of whom 73,045 were males above 16, 6,717 females above 15, and 3,217 youth. The capital invested amounted to \$94,368,057; wages paid during the year, \$31,100,244; value of materials, \$127,600,077; of products, \$205,620,672. The chief industries are exhibited in the following table:

INDUSTRIES.	No. of establishments.	Steam engines, horse power.	Water wheels, horse power.	Hands employed.	Capital invested.	Wages paid.	Value of materials.	Value of products.
Agricultural implements.....	294	2,575	91	3,935	\$5,350,978	\$1,818,835	\$3,598,897	\$8,880,380
Boots and shoes.....	1,210	4,600	2,190,615	1,084,164	2,079,647	4,448,794

—Illinois possesses remarkable commercial facilities in the Mississippi and Ohio rivers on its borders, besides numerous internal streams of importance. Bordering for about 70 m. on Lake Michigan, it is favorably situated for the immense lake commerce which centres at Chicago. This comprises not only the vast domestic trade for which this city is noted, but also a considerable foreign trade carried on with Canada and European ports. Provision was made for direct commercial relations between Chicago and foreign ports by the act of July 14, 1870, which authorizes the transshipment in bond of exports and imports to and from the ports of first arrival, without appraisement and payment of duties at such ports. The value of foreign imports received at Chicago under this system during the year ending June 30, 1873, was \$3,160,756. The total value of foreign imports subject to duty during the year was \$3,699,852, on which the duties collected amounted to \$1,535,631. The value of domestic produce exported from Chicago to Canada by lake was \$7,107,468; the most important items were wheat, \$5,737,022, and Indian corn, \$1,069,586. The leading article of import from Canada is lumber, of which 7,516,000 ft. was imported in 1873. The total number of vessels belonging to the customs district of Chicago in 1873 was 743, having an aggregate tonnage of 148,595; of these, 101 were sailing, 131 steam, and 511 unrigged vessels. The aggregate number of vessels that arrived was 11,858, having a tonnage of 3,225,911; of these, 22 were American vessels from foreign ports, 189 foreign vessels from foreign ports, and 11,647 were in the coasting trade. The number of clearances was 11,876, of which 483 were for foreign and 11,398 for domestic ports. Illinois has four ports of delivery, which, with the number and tonnage of vessels registered, enrolled, and licensed in 1873, were: Galena, 60 vessels, 7,781 tons; Quincy, 23 vessels, 2,443 tons; Alton, 5 vessels, 893 tons; Cairo, 36 vessels, 8,221 tons.

Ship building is carried on at Chicago, Cairo, and Quincy. In 1873, 21 vessels of 5,499 tons, including 10 sailing and 8 steam vessels, were built at Chicago, 4 at Cairo, and 1 at Quincy. —Illinois contains more miles of railroad than any other state in the Union. In 1850 the number of miles was 111. In the following year the construction of the Illinois Central, from the southern terminus of the Illinois and Michigan canal to Cairo, was begun, thus opening a channel of communication between Lake Michigan and the Mississippi river. The subsequent growth of the railroad system of the state was rapid. In 1855 there were 887 m.; in 1860, 2,790; in 1865, 3,157; in 1870, 4,823; in 1871, 5,904; and in 1872, 6,361. In 1873 the total mileage of main track completed and in operation, exclusive of double, side, and turnout tracks, was 6,496; in addition to which numerous lines were projected and in progress. The aggregate cost of the roads and equipments was reported by the railroad commissioners at \$238,584,541 in 1872, and \$278,386,784 in 1873. In 1872 the capital stock paid in was \$140,126,064; funded debts, \$111,456,325; floating debts, 330,173; amount of paid-up stock and debts, \$254,912,563. In August, 1873, the length of main track was returned by the state board of equalization at 5,064 m.; assessed at \$36,271,184; side, second, or turnout track, 863 m., valued at \$4,008,818; value of rolling stock, \$15,892,015; total value of property denominated railroad track and rolling stock, \$59,317,409; right of way and improvement, 64,733 acres, valued at \$3,145,173. This statement does not include the Illinois Central railroad, 705 m. The following table exhibits the names of the lines lying wholly or partly within the state, together with the termini, the number of miles completed and in operation within the state limits in 1873, the capital stock as reported by the commissioners, and the assessed value of the track and rolling stock as returned by the state board of equalization in August, 1873:

The state exercises a general supervision over the railroad companies within its limits. In the constitutional convention of 1870 the subject of railroad corporations was thoroughly considered, and a provision was incorporated in the new constitution requiring the legislature to pass laws establishing reasonable maximum rates of charges for the transportation of passengers and freight. In the following year a general railroad law was passed, which, having been pronounced in part unconstitutional by the state supreme court, was repealed, and a new one was passed in 1873. To secure the enforcement of such laws the legislature provided for the appointment by the governor of three railroad and warehouse commissioners, whose duty it is to examine into and report annually concerning the railroad and ware-

house interests of the state. By the act of 1873 every railroad company in the state is prohibited, under penalty of fines reaching as high as \$25,000 for the fourth offence, from charging more than a reasonable rate for the transportation of passengers or freight, and from making unjust discriminations in freight schedules. The companies are required to report in writing and under oath to the commissioners, and to comply with the schedules of reasonable maximum rates for transporting passengers and freight prepared by the commissioners. The latter are required to see that the law is obeyed, and to bring actions against the companies in case of violation. The navigation of Lake Michigan is connected with that of the Illinois river by the Illinois and Michigan canal, completed in 1848, which extends

from Chicago to La Salle, 96 m. The immense commerce which passes through this channel is indicated by the statement that in 1873 not less than 8,000,000 bushels of grain and 50,000,000 ft. of lumber, besides 20,000,000 shingles and laths, passed over the canal. Illinois in 1873 contained 9,545 m. of telegraph lines. The number of national banks in operation was 137, having a paid-in capital of \$20,843,000 and a circulation outstanding of \$16,326,059. The circulation per capita was \$7 02; ratio of circulation to wealth, 0·9 per cent.; to banking capital, 77·4 per cent.—By the constitution of 1870, the legislative power is vested in a general assembly composed of a senate and house of representatives. The senate consists of 51 members elected for four years, and the house of representatives of 153 chosen for two years. A decennial apportionment, beginning with 1871, is held. Senators must have attained the age of 25 years, and representatives 21 years. Elections for members of the general assembly are held biennially, in even years, on the Tuesday next after the first Monday of November. The sessions are biennial, commencing on the Wednesday next after the first Monday of January next following the election. Members receive \$5 a day and 10 cents for each mile necessarily travelled in going to and from the seat of government, and \$50 a session for stationery, &c. Special legislation, which was a source of much mischief under the old constitution, is prohibited in many enumerated cases, and “in all other cases where a general law can be made applicable.” The executive department consists of a governor, lieutenant governor, secretary of state, auditor of public accounts, treasurer, superintendent of public instruction, and attorney general, all of whom are elected for four years, except the treasurer, whose term of office is two years, and who is ineligible to the same office for two years next after the expiration of his term. A two-thirds vote of each house is necessary to pass a bill over the veto of the governor. The judicial powers are vested in a supreme, circuit, and county courts, justices of the peace, police magistrates, and certain special courts. The supreme court consists of seven judges, who are elected by the people for nine years, and receive a salary of \$4,000 a year. The chief justice is chosen by his associates. There are three grand divisions of the state, southern, central, and northern, in each of which one or more sessions of the supreme court are held annually. The judges of the circuit courts are elected by the people for six years, and receive an annual salary of \$3,500. The constitution further provides for the establishment of inferior appellate courts to be held by judges of the circuit courts. To these courts appeals and writs of error in certain cases may be taken from the circuit courts, and from them to the supreme court. Each county has a county court, the judge of which is elected for a term of four years. These courts have original

jurisdiction in all matters of probate, but probate courts may be established in any county having a population of over 50,000. There are special courts in Cook county, of which Chicago is the county seat. Imprisonment for debt is prohibited except upon the refusal of the debtor to deliver up his estate for the benefit of his creditors, or in cases where there is strong presumption of fraud. In trials for libel, the truth may be pleaded as a defence in justification. The legal rate of interest, in absence of agreement, is 6 per cent., but 10 per cent. may be agreed upon and collected. The penalty of usury is forfeiture of all the interest. Illinois is represented in congress by two senators and 19 representatives, and is entitled to 21 votes in the electoral college. The receipts into the state treasury for the two years ending Dec. 1, 1872, were \$9,899,603, and the expenditures \$12,351,746. The chief purposes for which the public money was used during this period were: legislative, \$693,062; executive, \$180,158; judicial, \$394,252; educational, \$2,208,264; educational and charitable, \$205,316; charitable, \$918,784; penal and reformatory, \$369,338; agriculture, \$39,007; commerce, \$238,661; state indebtedness, \$4,983,379; new state house, \$793,641. In 1872 the general assembly provided that the amount of revenue to be raised on the assessment of that and subsequent years should be \$1,500,000 for general purposes, to be designated the revenue fund, and \$200,000 for payment of interest on the state debt. The governor and auditor are required annually to compute such rates as will produce these amounts. The rates computed on the equalized valuation for 1872 were 3·53 mills for revenue purposes and 0·47 mill for interest on the state debt. Besides these, provision was made for an annual levy of 2 mills for the support of common schools and 1·5 mill for “canal redemption fund;” making the total levy for state purposes 7·5 mills on the assessment of 1872. The total levy for 1873 was 3·6 mills, being 2·7 mills for general revenue purposes and 0·9 mill for school fund. The state debt in 1863 was \$12,280,000; in 1870, \$4,890,937; and in 1874, \$1,706,750. The valuation of property for the purposes of taxation, for a series of years, has been:

YEARS.	Real estate.	Personal property.	Railroad property.	Total valuation.
1840...				\$58,752,168
1850...	\$56,522,237	\$93,395,799		119,563,336

1872...	371,610,940	113,607,950	25,658,784	510,886,683
1873...	399,434,748	303,119,271	133,807,823	1,341,361,842

Included in the valuations of personal property for 1873 is \$20,826,462 assessed as valuation on corporations other than railroads. It will be noticed that the valuations for 1873 are largely in excess of any previous year; these results, however, do not represent a corresponding increase in the value of property, but are attributed in a large measure to the operations of a new revenue law. The valuations for 1873 are believed to be about 0.65 per cent. of the cash value of real and personal property, and still nearer the entire value of railroad property.—The charitable and correctional institutions are under the general supervision of the board of state commissioners of public charities, consisting of five members appointed by the governor with the consent of the senate, whose duty it is annually to inspect the state institutions under their charge, together with the various county jails and almshouses, and report upon their condition. The statistics showing the extent and condition of the correctional, charitable, and educational institutions of the state are generally for 1872, the date of the most recent biennial reports. The state penitentiary, which has been at Joliet since 1859, was organized in 1827, and at the beginning of 1873 contained 1,255 convicts, the average number for the year being 1,283. It has recently become self-sustaining under the system of leasing the labor of the convicts; the total earnings in 1872 were \$214,593, while the expenses were \$36,218 less. Instruction is afforded to the inmates, and there is a library of about 4,000 volumes. The reform school at Pontiac, opened in 1871, has accommodations for about 150 inmates, which are inadequate to the needs of the state. About 900 pupils have been admitted to the institution for the education of the deaf and dumb at Jacksonville since its opening in 1845, and about 300 were receiving instruction from 16 instructors at the beginning of 1874. The course of instruction occupies eight years. Pupils within the state are admitted to the school free of charge, and are supplied with all necessities except clothing. A prominent feature of the institution is its industrial department. The annual cost to the state for each pupil is about \$250. Its accommodations are entirely inadequate. The building used for the instruction of the blind, also at Jacksonville, was destroyed by fire in 1869; new buildings for purposes of instruction and workshops are in process of construction, with grounds comprising 18 acres. In 1874 about 70 pupils were receiving instruction from four teachers; the course of instruction is five years. The charitable eye and ear infirmary, created in 1865, is an efficient institution, affording gratuitous medical treatment to all applicants who are citizens of the state. The foundations for a neat, substantial edifice for this institution have been laid in the West Division of Chicago. Provision is made for the insane by the hospital at Jacksonville, the northern asylum at

Elgin opened in 1872, and the southern asylum at Anna opened in 1873; the two latter are in process of construction. At the close of 1872 the northern asylum had 183 inmates and the southern 75. The hospital at Jacksonville is constructed on the corridor plan, is five stories high, and comprises a central building with two wings. The accommodations were intended for about 400 patients, though the average number for two years has been 450. The grounds comprise 160 acres. The whole number of patients admitted since the opening of the hospital in 1851 has been 4,527, of whom 1,685 were discharged recovered, 606 improved, and 400 unimproved; 328 improved and unimproved were discharged by order of the trustees, and 467 died. The superintendent of this institution estimates the number of insane in the state at 2,529, or 1 in every 1,000 inhabitants. The hospital accommodations of the state are greatly inadequate to this number. Those under treatment cost the state about \$250 a year each. The manner of committing insane persons to the hospital is by jury trial in the county courts. According to the state board of public charities, the proportion of idiots in the state is at least as large as that of the insane. The institution for the education of feeble-minded children at Jacksonville was created in 1865, and has accommodations for about 100. Only those whose condition can be improved are admitted. The success of the institution and the importance of providing this kind of instruction have recently led to efforts which will result in largely increased facilities for improving this class of unfortunates. The home for the children of deceased soldiers, at Normal, opened in 1867, comprises three main buildings and 80 acres of land. Here support and instruction are afforded to children of this class under 16 years of age. The average attendance during 1873 was 306, while the number of inmates at the close of the year was 326. The current expenses for the year amounted to \$58,389. Besides supporting this institution, the state has aided the soldiers' college at Fulton and the soldiers' home in Chicago, both of which are private institutions.—An efficient system of free schools is provided for all the children of the state, but the constitution prohibits appropriations of public money for sectarian schools. The educational interests of the state are under the general supervision of the superintendent of public instruction. The tax that may be levied in any district for all current school expenses is limited to 2 per cent. for educational and 3 per cent. for building purposes upon the assessed value of the taxable property of the district. Every district is required to maintain a free school at least five months in the year as a condition of receiving a share of the state school funds. Examinations of teachers are held and certificates issued by the county superintendents, and only teachers having such certificates are em-

ployed in the public schools. A marked feature recently introduced into the educational system of this state is the requirement making the elements of natural science a part of the common-school course. The permanent school funds of the state comprise: 1, the school fund proper, being 3 per cent. upon the net proceeds of the sales of the public lands in the state, one sixth part excepted; 2, surplus revenue, derived from the distribution in 1836 of the surplus revenue of the United States; 3, the college fund, being one sixth of the 3 per cent. fund originally required by congress to be devoted to the establishment and maintenance of a state college or university; 4, the seminary fund, derived from sales of lands granted to the state by the general government for the establishment of a state seminary; 5, county funds, created by the legislature in 1835; 6, township funds, arising from the sales of public lands granted by congress for common-school purposes. The aggregate amount of these funds on Sept. 30, 1872, was \$6,382,248, as follows: school fund proper, \$613,363; surplus revenue, \$335,592; college fund, \$156,613; seminary fund, \$59,839; county funds, \$348,285; township funds, \$4,868,555. The total income for school purposes in 1872 from these funds and the current school funds was \$7,500,122; the chief items of the income from current funds being \$900,000 from the two-mill tax, and \$5,292,942 raised by *ad valorem* tax in the districts for general purposes. The condition of the common schools in 1872, according to the latest biennial report of the superintendent of public instruction, was as follows:

Number of school districts.....	11,231
" " " houses.....	11,289
" " " public schools (high 88, graded 611, ungraded 10,697).....	11,976
Average duration of schools.....	27 days
Persons between 6 and 21 years of age.....	882,698
Number enrolled in schools.....	662,049
Average daily attendance.....	329,799
Number of teachers (male 9,094, female 11,890)....	20,984
Average monthly salaries of male teachers.....	\$50 00
" " " female teachers.....	\$39 00
Total annual cost per pupil on school census.....	\$5 61

Number of private schools.....	436
" pupils in private schools.....	34,784
" volumes in district libraries.....	54,286
" persons between 12 and 21 years of age unable to read and write.....	6,753

The state normal university, for the training of teachers, at Normal, was organized in 1857, and comprises, besides the usual departments, a model school. The course of instruction is three years, upon the completion of which a diploma is conferred. In 1873 there were 13 instructors, besides a large number of pupils acting as teachers, and 730 pupils, of whom 437 were in the normal and 293 in the model school. The southern Illinois normal university, at Carbondale, was completed in 1874. In addition

to these state institutions, there are county normal schools in Cook and Peoria counties, a German-English normal school at Galena, and normal departments connected with several other institutions. For the further instruction of teachers, numerous county institutes are held, besides occasional sessions of the state teachers' institute. The Illinois industrial university, opened in 1868, is both state and national, having been organized by the legislature, and having received the national grant of lands intended for the establishment of colleges of agriculture and the mechanic arts. This institution is situated at Urbana, where it has one of the finest buildings of the kind in the country, being four stories high and 214 ft. long, with a depth on the wings of 122 ft. The grounds comprise 623 acres, including stock farm, experimental farm, orchards, gardens, nurseries, forest plantations, arboretum, botanic garden, ornamental grounds, and military parade ground. The property and funds of the university amount to nearly \$800,000. Students of both sexes are admitted. The university embraces a college of agriculture, comprising a school of agriculture proper and a school of horticulture and fruit growing; a college of engineering, with schools of mechanical science, civil and mining engineering, and architecture; a college of natural science, with schools of chemistry and natural history; and a college of literature and science, with a school of English and modern languages and one of ancient languages and literature. There are also schools of commerce, military science, and domestic science and arts. Entire freedom in the choice of studies is allowed to each student; but the completion of one of these courses or the prescribed equivalents is necessary to graduation. The number of pupils in 1873 was 402, of whom 74 were females. The Illinois agricultural college, at Irvington, organized in 1866, had 226 students and 6 instructors in 1873. The course of instruction is four years. Besides the buildings in use, the institution has 550 acres of land. According to the census of 1870, Illinois had 26 colleges, with 223 instructors and 4,657 pupils; 32 academies, with 201 instructors and 4,690 pupils; 2 law schools, with 3 instructors and 61 students; 2 medical schools, with 19 instructors and 358 pupils; 9 theological schools, with 28 instructors and 575 pupils; besides 2 schools of agriculture, 2 of commerce, and 2 of art and music. Six of these institutions were classified as universities. Besides the above named, there were 531 private day and boarding schools, with 1,526 teachers, of whom 1,035 were females, and 41,456 pupils, of whom 21,044 were females. The total number of schools, public and private, was 11,835, having 24,056 teachers, of whom 13,645 were females, and 767,775 pupils, including 377,820 females. The total income of all the educational institutions was \$9,970,009, of which \$252,569 was derived from endowments,

\$6,027,510 from taxation and public funds, and \$3,689,930 from other sources, including tuition. The most important facts concerning the colleges and universities of Illinois are given in the article COLLEGE. The following

statement shows the extent and condition of the institution for the advanced instruction of females and professional schools, as reported by the United States bureau of education in 1873:

NAME OF INSTITUTION.	Where situated.	Denomination.	Date of organization.	Number of teachers.	Number of pupils.
FOR SUPERIOR INSTRUCTION OF FEMALES:					
Seminary of the Sacred Heart.....	Chicago.....	Roman Catholic.....	1858	27	120

Chicago college of pharmacy.....		1859	4	50
Hahnemann medical college (homoeopathic).....		1859	16	65

—According to the census of 1870, the number of libraries was 13,570, containing 3,323,914 volumes. Of these, 9,865 with 2,399,369 volumes were private, and 3,705 with 924,545 volumes other than private, including 79 circulating libraries containing 75,352 volumes. The largest libraries in the state were destroyed by the great Chicago fire in 1871. The chief libraries reported by the United States bureau of education in 1872 were that of the Northwestern university at Evanston, containing 22,000 volumes; the state library in Springfield, 15,000; that of the Baptist union theological seminary in Chicago, 15,000; the Hengstenberg library (university of Chicago), 13,000; that of the Illinois industrial university at Champaign, 10,000; Illinois college, Jacksonville, 8,000; McKendree college, Lebanon, 8,000; Augustana college, Paxton, 7,000; and the mercantile library, Peoria, 7,000. The state law library in Springfield contains 3,000 volumes, and the Chicago public library (1874) about 40,000. The total number of newspapers and periodicals reported by the census of 1870 was 505, with an aggregate circulation of 1,722,541, and issuing 113,140,492 copies annually. There were 39 daily, circulation 166,400; 10 tri-weekly, 40,570; 4 semi-weekly, 2,950; 364 weekly, 890,913; 11 semi-monthly, 107,900; 72 monthly, 490,808; 2 bi-monthly,

11,000; and 3 quarterly, 12,000. In the same year the state contained 4,298 religious organizations, having 3,459 edifices with 1,201,403 sittings, and property valued at \$22,664,283. The leading denominations were:

DENOMINATIONS.	Organizations.	Edifices.	Sittings.	Property.
Baptist.....	722	571	181,454	\$2,601,612

—Illinois takes its name from its principal river. According to Albert Gallatin, the term is derived from the Delaware word *leno*, *leni*, or *illini*, meaning real or superior men, the termination being of French origin. The first settlements were made by the French, and were the consequence of the enterprises of Marquette (1673) and La Salle. The latter traveller set out from Canada in 1679, and passing across the lakes descended the Illinois river. After examining the country, with which he was highly pleased, he returned to Canada, leaving the chevalier de Tonti in command of a small fort he had built at the foot of Lake Peoria and named Crève-cœur. In 1682 he returned to Illinois with a colony of Canadians, and founded Kaskaskia, Cahokia, and other towns. At the beginning of the 18th century the settlements in Illinois are represented to have been in a flourishing condition, and the country was described by French writers as a new paradise. As the colonies of France and England extended, disputes arose respecting boundaries, and these ultimately led to the war which virtually ended with the capture of Quebec, and which in 1763 terminated the French dominion over any part of the country E. of the Mississippi. During the continuance of Illinois as a British dependency nothing of importance appears to have occurred, nor were the French settlements molested. After the peace of 1783, which closed the American revolution, the Illinois country was ceded to the United States; and by the ordinance of July 13, 1787, the whole of the public domain N. of the Ohio river was erected into the Northwest territory under a single government. In 1800 the territory contained a population of 50,240, and in the same year Ohio was erected into a separate territory. A further severance was made in 1805, when the territory of Michigan was formed, and again in 1809 Indiana was divided off. The Illinois territory at this time included what are now the states of Illinois and Wisconsin and a part of Minnesota, and by the census of 1810 was found to contain 12,282 inhabitants. Hitherto the settlement of these territories had been greatly impeded by Indian hostilities, and indeed the early history of Illinois is one continued narrative of contests with the savages. Among the prominent events of this period is the massacre near Fort Chicago, Aug. 15, 1812. When hostilities finally ceased, population began to flow in from the eastern states. On Dec. 3, 1818, Illinois with its present limits was admitted as a state into the Union. The census of 1820 returned 55,211 inhabitants. During the succeeding decade immigration increased rapidly, and in 1830 the population was ascertained to be 157,445, or an increase of 185·2 per cent. over that of 1820. In 1831 the Sac and other Indian tribes began to be troublesome, and in 1832 the Black Hawk war broke out. The alarm caused by these hostilities was great, but the result was ultimately beneficial

to the state; not only was a permanent peace conquered, but the officers of the army on their return reported so favorably of the character and resources of the country, that general attention was directed to the state. Shortly afterward congress granted an appropriation for the improvement of Chicago harbor, and about this time the Illinois and Michigan canal was projected, and the state bank brought into successful operation. On July 4, 1836, the construction of the canal was commenced. The succeeding year brought the greatest financial revulsion in our history, and in this no state was more seriously involved than Illinois. Every interest was prostrated, and all works of internal improvement abandoned. The progress of the state, however, had been rapid, and by the census of 1840 the population numbered 476,183, being an increase of 203·4 per cent. over that of 1830. In this year the Mormons established themselves at Nauvoo, and were from the first disliked by their neighbors. Mutual hatred ended in open hostilities, and at length the brothers Joseph and Hyrum Smith (the first named the founder of Mormonism) were arrested, and while confined in Carthage jail were murdered by a mob, June 27, 1844. This was soon followed by a general exodus of the Mormons, who now numbered about 20,000, toward Utah. In 1847 a new constitution was framed, which went into operation in the following year. The census of 1850 showed a population of 851,470, an increase of 80·7 per cent. in the decade. This was a much lower rate of increase than had hitherto been maintained, but was still a rapid growth. In the mean while emigration had been directed to Iowa and Wisconsin. But a new era of prosperity was now opening for Illinois. In the same year congress made a munificent grant of land in aid of the construction of the Central railroad, which was completed in 1856. The country along both sides of its route has been rapidly settled, cities and towns have risen with remarkable rapidity, and the prosperity of the state through the influence of this and other great works simultaneously completed has become so general that the last acre of government land in Illinois has been disposed of. In December, 1869, a constitutional convention assembled, and in May following agreed upon the present constitution, which was ratified July 2. In this instrument the system of "minority representation" in the election of members of the house of representatives was incorporated, it being provided that "in all elections of representatives aforesaid, each qualified voter may cast as many votes for one candidate as there are representatives to be elected, or may distribute the same, or equal parts thereof, among the candidates, as he shall see fit; and the candidates highest in votes shall be declared elected."—A "History of Illinois, 1673-1873," by Alexander Davidson and Bernard Stuvé, was published in 1874, and is authority for some of the statements here made.

ILLINOIS, a river of the United States, and the largest in the state to which it gives its name. It is formed in Grundy co., in the N. E. part of the state, about 45 m. S. W. of Lake Michigan, by the union of Kankakee and Des Plaines rivers, the former of which rises in the N. part of Indiana and the latter in the S. E. part of Wisconsin. The Kankakee receives the Iroquois, and from that point to its junction with the Des Plaines is sometimes known as the Iroquois. The Illinois flows nearly W. to Hennepin, in Putnam co., and thence S. W. and finally S. until it unites with the Mississippi between Calhoun and Jersey counties, 20 m. above the mouth of the Missouri. It is about 500 m. long, and is navigable at high water for 245 m. It is deep and broad, in several places expanding into basins which might almost be called lakes. Peoria, the most important city on its banks, is built on the shore of one of these basins. Its principal affluents are the Fox, Spoon, Crooked creek, the Mackinaw, Sangamon, and Vermilion. Above the mouth of the Vermilion, in La Salle co., it is obstructed by rapids, and a canal has been built from this point to Chicago, a distance of 96 m. Uninterrupted water communication is thus secured between the lakes and the Mississippi. The Illinois was ascended by Marquette in 1673, and explored in 1679-'80 by La Salle and Hennepin, who entered it by the Kankakee, which they reached from Lake Michigan by means of the St. Joseph river and a short portage, and sailed in canoes, La Salle as far as the present site of Peoria, and Hennepin to the Mississippi. In 1682 La Salle navigated the whole course of the river.

ILLUMINATI (Lat., the enlightened), a name supposed to have been given to the newly baptized in the early Christian church, because a lighted taper was put into their hands as a symbol of enlightenment; subsequently a name assumed at different periods by sects of mystics or enthusiasts who claimed a greater degree of illumination or perfection than other men. The most famous of these sects were the Alombrados or Alumbrados (the enlightened) in Spain at the end of the 16th century; the Guérinets, named after their founder Pierre Guérin, in France in the 17th century; and an association of mystics in Belgium in the 18th. The most celebrated society of the name was that founded in 1776 by Adam Weishaupt, a German professor of canon law at Ingolstadt, and a man of great originality and depth of thought, with the ostensible object of perfecting human nature, of binding in one brotherhood men of all countries, ranks, and religions, and of surrounding the persons of princes with trustworthy advisers. Apostles, styled areopagites, were sent to various parts of Europe to make converts, and before the existence of the society became generally known branches had been established in various parts of Germany, in Holland, and in Milan. Young men from 18 to 30 years of age, and Lutherans rather than

Roman Catholics, were preferred as members. The illuminati gained much influence by the accession to their ranks of Knigge the author, and by the sympathy of many freemasons. At the height of its prosperity the society had 2,000 members. The order was divided into three classes and several subdivisions. The first, or preparatory class, was divided into novices, minervals, and *illuminati minores*. The second class was that of the freemasons, who were ranked as apprentices, assistants, and masters; it included two higher grades, that of the *illuminatus major*, or of the Scottish novice, and that of the *illuminatus dirigens*, also called the Scottish knight. The class of mysteries was divided into major and minor mysteries, of which the latter included the two grades of priests and regents. The major mysteries comprised the grades of *magus* and *rex*. The mysteries related to religion, which was transformed into naturalism and free thought, and to politics, which inclined to socialism and republicanism. The order corresponded in cipher, and used a peculiar phraseology; January was called Dimeh; February, Beumeh; Germany, the Orient; Bavaria, Achaya; and Munich, Athens. Every illuminatus received a new name; Weishaupt was Spartacus, and Knigge was Philo. But Knigge and Weishaupt could not agree, and this, as well as the opposition of the Roman Catholic clergy, proved fatal. The society was prohibited by the Bavarian government in 1784, and its papers were seized and published under the title *E-nige Originalschriften des Illuminatenordens, auf höchsten Befehl gedruckt* (Munich, 1787). Works on the subject were published by Weishaupt, Knigge, Nicolai, and Voss (1786-'99).

ILLYRIA (anc. *Illyricum* and *Illyris*; Ger. *Illyrien*), a name anciently applied to all the countries on the east coast of the Adriatic, the adjacent islands, and western Macedonia, inhabited by the Illyrians, a tribe believed to have had a common origin with the Thracians. Philip of Macedon subdued the Illyrians east of the river Drilo (now Drin), 359 B. C. Illyricum was subsequently divided into Illyris Græca and Illyris Barbara. The latter soon became a Roman province, designated as Illyris Romana, and included a part of the modern Croatia, the whole of Dalmatia, almost the whole of Bosnia, and a part of Albania. The principal tribes after whom the districts were called were the Japydes, Liburni, and Dalmatians. The Liburni were the first subdued by the Romans; and after the conquest of the Dalmatians, in the reign of Augustus, the entire country became a Roman province. After that time the Illyrians, and particularly the Dalmatians, formed an important part of the Roman legions, and were esteemed the most warlike of the empire. Illyris Græca, or Illyria proper, embraced the greater part of the modern Albania. The territory of this division consisted principally of mountain pastures, with some fertile valleys. The various tribes of the Grecian Illyrians

were generally poor, rapacious, and fierce; in earlier times the tribe of the Autariatæ held the first rank as warriors. They had the customs of tattooing and of offering human sacrifices, and were always ready to sell their military services to the highest bidder, like the modern Albanian Shkipetars, in whom probably their blood yet flows. The Illyrians supplied the Greeks with cattle and slaves, often in exchange for salt. Grecian exiles found their way into Illyria, and Grecian myths became localized there. After the death of Alexander the Great most of the tribes recovered their independence, but their piracies gave umbrage to the Romans. The Roman ambassadors who protested against their depredations were murdered by the Illyrian queen Teuta. The first Illyrian war was commenced in 230 B. C., and the queen was obliged in 229 to make peace by the surrender of part of her dominions. The second war, commenced by Demetrius of Pharos, the guardian of the Illyrian prince Pineus, was successfully terminated by the consul L. Æmilius Paulus in 219. Pleuratus, the successor of Pineus, cultivated the friendship of the Romans, but his son Gentius formed an alliance with Perseus, king of Macedon. He was conquered in the same year as Perseus, and Illyria as well as Macedon became subject to Rome (168). In the new organization under Constantine, Illyricum was one of the great divisions of the empire, and was divided into Occidentale, including Illyricum proper, Pannonia, and Noricum, and Orientale, comprising Dacia, Mœsia, Macedonia, and Thrace. On the fall of the western empire (A. D. 476) it remained a part of the eastern. About two centuries later the Slavic settlers from northern Europe separated themselves from the Byzantine government, and laid the foundation of the governments of Croatia and Dalmatia. At the end of the 11th century some portions of the Illyrian territory were taken by Venice and Hungary. About a century later the kingdom of Rascia was created, out of which Servia and Bosnia were subsequently formed. Dalmatia passed successively through the hands of the Venetians, Hungarians, and Turks. Venice retained only a small portion of Dalmatia, while Hungary kept Slavonia and part of Croatia. Austria obtained Dalmatia and adjacent islands by the treaty of Campo Formio in 1797.—The name Illyria, which had gradually disappeared, was revived in 1809 by the organization of the Illyrian provinces by Napoleon, comprising the territories of Carniola, Carinthia, Istria, part of Croatia, Dalmatia, Ragusa, and a military district, with a population of 1,275,000. After the fall of Napoleon they were reunited to the Austrian government, which in 1816 raised Illyria to the nominal dignity of a kingdom. It embraced the duchies of Carniola, Carinthia, Friuli, and Istria, the Hungarian Coastland, part of Croatia, and the islands in the gulf of Quarnero, having an area of about 11,000 sq. m. The Coastland and

Croatia were separated from it in 1822, and reunited with Hungary, where they have formed since 1849 part of Croatia and Slavonia. The kingdom was dissolved in the same year into the crownlands of Carinthia, Carniola, and the Littorale. The Illyrian language is one of the southern branches of the Slavic family of languages. (See SERBIAN LANGUAGE AND LITERATURE.)

ILOPANGO, a lake of Central America, in the republic and 6 m. S. E. of the city of San Salvador. It is about 14 m. long by 6 broad, and is clearly of volcanic origin. On all sides it is surrounded by high, abrupt hills, composed of scoriæ and volcanic stones. It receives no tributary streams, although it has a small outlet, flowing through a dark narrow ravine into the Rio Jiboa, near the base of the volcano of San Vicente. The surface of the water is not less than 1,200 ft. below the level of the surrounding country. When the surface is ruffled by a breeze, it takes a brilliant green color, and exhales a disagreeable sulphurous odor.

IMAGE WORSHIP. See ICONOCLASTS.

IMBERT, Barthélemi, a French poet, born in Nîmes in 1747, died in Paris, Aug. 23, 1790. His poem entitled *Jugement de Pâris* (1772) passed through many editions, and he also published fables, plays, and novels, the best of the latter being *Les égarements de l'amour* (1776). His *Œuvres poétiques* appeared in 2 vols., 1777; his *Œuvres diverses* in 1782; and his *Œuvres choisies en vers* in 4 vols., 1797.

IMMACULATE CONCEPTION, a doctrine of the Roman Catholic church which teaches that the Virgin Mary was in her conception exempt from all stain of original sin. Though this belief had been held in the eastern and western churches from a remote antiquity, it was not defined as an article of faith until Dec. 8, 1854. It is formally stated in the constitution of Pius IX., *Ineffabilis Deus*, in the following words: "We define the doctrine which holds the most blessed Virgin Mary in the first instant of her conception to have been preserved free from all stain of original sin, by the singular grace and privilege of Almighty God and through the merits of Jesus Christ the Saviour of the human race, to be a doctrine revealed by God, and therefore to be firmly and constantly held by all the faithful." The decree itself is further explained by the annexed passage from the constitution *Sollicitudo omnium Ecclesiarum* of Alexander VII.: "It is an ancient belief of Christ's faithful with regard to his virgin mother, that her soul in the first instant of its creation and union with the body was, by a special grace and privilege of God, . . . preserved free from the stain of original sin; and it is in this belief that they honor and celebrate the feast of her conception." The defined doctrine therefore refers not to the active but to the passive conception, that is, to the soul and body of the Virgin in the first instant of their creation and union; at that instant, in view of the merits of the Son,

the mother, in body and soul, was exempt from the common law of fallen humanity. The controversy within the Roman Catholic church on the immaculate conception was more in regard to the terms of the doctrine and the mode and time of the immaculateness than to the Virgin's freedom from the effects of original sin, which for the most part was not denied. The establishment of the feast of the conception witnesses to the fact; as the church could not celebrate a festival in honor of a conception in sin. This festival was celebrated at a very early day in the East, and it is almost impossible to fix the precise date of its introduction in the West; it was probably during the 8th and 9th centuries. In the East there seems to have been no discussion in regard to the observance of this festival. In the West it began to be observed by the devotion of particular churches before the sanction of the apostolic see had made it universal. St. Bernard reproved the canons of Lyons because they had established this feast without waiting for the decree of the supreme pontiff. The agitation of the question led to long disputes among theologians, and especially among the Franciscans and Dominicans; the latter have been ranked among the pronounced opponents of the doctrine. The disagreement was, however, one of terms rather than of doctrine. Thus Thomas Aquinas, who is most eminent among the Dominican theologians, expressly declares the exemption of the Virgin Mary from original sin: "*Talis fuit puritas B. Virginis, quæ peccato originali et actuali immunis fuit.*" (*Com. in I Liber. Sent., Dist. 44, § 3.*) The objections of St. Bernard also are against the immaculate conception "actively" considered, which is no part of the Roman Catholic dogma. The discussion of the subject in the schools led to repeated declarations in its favor. Duns Scotus in 1307, in a disputation before the university of Paris, maintained the doctrine of the Virgin's immaculateness in its highest sense; and the whole Franciscan order thenceforward zealously defended it. The university itself in 1387 condemned certain propositions of John de Montesano, a Dominican, in which the doctrine was denied, and in 1497 passed a decree that no one should be admitted to any academic honor who did not bind himself by oath to defend it. In 1439 the council of Basel, during its schismatic period, declared the "belief of the immaculate conception of the Virgin to be conformable to the doctrine and devotion of the church, to the Catholic faith, right reason, and the Holy Scriptures, and to be held by all Catholics." The council of Trent, in its decree concerning original sin, expressly declared that it did not intend to include the immaculate Virgin, and ordered the decrees of Sixtus IV. to be observed. During all the controversy the holy see interfered only occasionally, but these interferences were successive steps toward the formal definition of the doctrine. Sixtus IV., in the apostolic let-

ter entitled *Grave nimis*, published in 1480, imposes excommunication upon any one who accuses of heresy either the advocates or the opponents of the immaculate conception, while at the same time he condemns all who affirm as the truth the opinion that the Blessed Virgin was conceived in sin. He also granted indulgence to those who should assist at mass or office on the feast of her conception. Pius V., in the bull 114, *Super Speculam*, in 1570, prohibited the public discussion of the question, renewing also the decree of his predecessor. Paul V. in 1616 forbade any one to affirm by any public act whatever that the Virgin was conceived in sin, while he also prohibited the open condemnation of this opinion. Gregory XV. in 1622 prohibited either the public or private denial of the immaculate conception, allowing no discussion whatever on the subject except to the Dominicans, to whom an especial privilege was reserved. The office and mass of the conception were however made binding upon them as upon all Catholics. In 1661 Alexander VII., in the constitution *Sollicitudo omnium Ecclesiarum*, declares the opinion that the Virgin was conceived without original sin to be almost universal in the church; therefore he renews the decrees of his predecessors, commanding that they be observed in favor of the feast and cultus of the conception, and moreover deprives of the faculty of teaching or preaching any one who should call into doubt or misinterpret the favor shown to this opinion by asserting anything against it, or even by bringing forward arguments against it. After that time the congregation of rites repeatedly interposed its mandate in favor of the doctrine. The word immaculate was added in the office and mass of the conception, and its use made binding upon all priests, even those of the Dominican order. Pius IX. in the early part of his reign sent letters to all patriarchs and bishops, requesting their opinion upon the propriety of defining the doctrine. Answers were given by 620 bishops and archbishops, of whom only four were opposed to the definition on dogmatic grounds, and even these gave testimony that their clergy and people were united in the belief of the doctrine. When replies were received from nearly the whole Catholic episcopate, as many of the bishops as possible were invited to be present in Rome to assist at the solemn definition of the doctrine. This ceremony took place with great pomp in the basilica of St. Peter, in the presence of more than 300 archbishops, bishops, and prelates, on the feast of the immaculate conception, Dec. 8, 1854. In September, 1857, a monument was inaugurated by the pope at Rome in commemoration of the decree. On this occasion he also established the "Archconfraternity of the Immaculate Conception," which now has branches in all Catholic countries.—In 1618 a military order of the Conception was established in Italy by Duke Ferdinand I. of

Mantua, for promoting peace among Christian princes; this order was confirmed in 1625 by Urban VIII., who gave to the members the rule of the third order of St. Francis. It was composed of noblemen, and rapidly acquired great importance; but political events caused its dissolution. In Portugal John VI. founded, Feb. 6, 1818, the military order of "Our Lady of the Conception of Villaviciosa."

IMMERMANN, Karl Lebrecht, a German author, born in Magdeburg, April 24, 1796, died in Düsseldorf, Aug. 25, 1840. He qualified himself at Jena for the Prussian judiciary service, in which he found employment, and became at the same time known as a dramatist and poet. He received a judicial appointment at Düsseldorf in 1827, and resumed his professional duties after having incurred heavy losses in a disinterested attempt to manage the Düsseldorf theatre in conformity with high conceptions of art. He published admirable tragedies, such as *Alexis* and *Merlin*, and fine comedies, but they were not adapted for the stage. His other productions comprise an entertaining fairy tale, *Tulifantchen*, several volumes of poetry and miscellaneous writings, and a novel in imitation of Goethe's *Wilhelm Meister* entitled *Die Epigonen* (2 vols., 1836); but his great fame chiefly rests upon his *Münchhausen* (4 vols., 1838-'9), which passed through several editions. His complete works were published in 14 volumes (Düsseldorf, 1834-'43). See his *Memorabilien* (Hamburg, 1840, unfinished); Freiligrath's *Karl Immermann, Blätter der Erinnerung an ihn* (Stuttgart, 1842); and his biography by Putlitz (2 vols., Berlin, 1870).

IMMORTElLES, a name given by the French to those flowers which from their papery nature

up into wreaths, crosses, and other designs, is *helichrysum orientale*, a perennial composite from the island of Crete (and formerly called *gnaphalium*), which, upon stems about a foot high, bears dense clusters of bright yellow globular flower heads, about the size of a large pea; as far north as Paris this is a tender plant, but in the south of France large quantities are raised to supply the demand. The usual French immortelle wreath consists of these in their natural color, made into a heavy circle with a motto worked in of the same flowers dyed black. There are several annual species and varieties of *helichrysum*, with much larger flowers and of various colors, that are common in our gardens, where they are cultivated for making winter bouquets. These and all other everlasting flowers should be gathered before they have fully expanded, tied in small bunches, and hung up to dry. Other plants of the *compositæ* used for the same purpose are

Ammobium alatum.

Helichrysum orientale.

do not wither on drying, known in this country as "everlasting flowers," and are furnished by plants in widely different families. The immortelle so largely used by the French, made

acroclinium roseum, with a white variety; *ammobium alatum*, small white; *helipterum Sanfordii* and *H. corymbosum*, yellow and white; *rhodanthe Manglesi* and its varieties, from white to dark purple, the most beautiful and delicate of all, whether fresh or dry; *Waitzia aurea* and *xeranthemum annuum*, with white, blue, and purple varieties. Besides these, the globe amaranths (*gomprena*), several species of *statice*, and *gypsophila* are cultivated for drying. Quite as pretty as any of these exotics is our pearly everlasting, *antennaria margaritacea*, which is common all over the northern states on dry knolls and in woods; this if gathered sufficiently early makes a fine immortelle, and being white, may be colored according to fancy. Considerable quantities of immortelles are imported by American seedsmen, both in bunches and made up in bouquets, baskets, and designs. One establishment in Prussia has 100 acres devoted entirely to their cultivation.

They are sent out in their natural colors, or more frequently dyed; most of them have to be bleached before dyeing, which is done by sulphur fumes, chlorine, or acids, according to

Rhodanthe Manglesii.

the kind, and afterward colored, usually with aniline dyes. Of late years there have appeared among the immortelles larkspurs, roses, and other flowers not ordinarily so classed; these are preserved by exposing them thoroughly to sulphur fumes and afterward drying them, when most flowers regain the color that sulphur has temporarily removed.

IMOLA, a town of Italy, in the province and 20 m. S. E. of the city of Bologna, on a small island of the Santerno, on the road from Bologna to Faenza; pop. in 1872, 28,398. It is the seat of a bishop, and has an ancient castle, a cathedral, a gymnasium, a technical school, noted manufactories of tartar, and an active trade in wine, flax, hemp, rice, and corn. Imola is believed to be the ancient Forum Corneli, which was founded by Sulla. Pius VII. and Pius IX. were bishops of Imola before becoming popes.

IMOLA, Innocenzio da, a Bolognese painter, whose real name was Francucci, born at Imola in the latter part of the 15th century, died about 1550. He was a pupil of Francia, and resided chiefly in Bologna, where his painting of the archangel Michael subduing Satan is now preserved. In the latter part of his life he imitated Raphael, and some of his works have been mistaken for his.

IMPEACHMENT (Fr. *empêchement*, hindrance, obstruction), the accusation and prosecution, in a legislative body, of a person for treason or other high crimes. By the law of England, any member of the house of commons may impeach any other member of the house, or any lord of parliament, or indeed any other officer of the realm. Upon such impeachment being made, the house of commons, if they see fit, exhibit articles of impeachment before the

house of lords, and appoint managers to sustain the charge and conduct the trial; and upon the trial, the same rules of evidence, in general, are in force as in trials in the ordinary courts of justice. This is a very solemn procedure, it being a prosecution before the supreme court of criminal jurisdiction for the whole realm, by the grand inquest thereof. It has been most frequently used against the king's ministers; and in order to take the trial from the power of the king, it is provided by law that the impeachment is not abated either by the prorogation or dissolution of parliament. The latest and best known cases are those of Warren Hastings (1788) and of Lord Melville (1806). In the United States, impeachment is a written charge and accusation by the house of representatives of the United States, made to the senate of the United States, against an officer thereof; or, in a state, it is such an accusation of an officer, by the representatives of the state, before the senate. The proceedings, rules, and practice in cases of impeachment in this country are borrowed from the common law of England, excepting so far as they are affected by the constitution or statutes of the United States, or of the several states. The constitution of the United States declares (art. i., sec. 2) that the house of representatives shall have the sole power of impeachment, and (art. i., sec. 3) that the senate shall have the sole power to try all impeachments. By art. ii., sec. 4, the persons made liable to impeachment are the president, the vice president, and all civil officers of the United States. The offences for which a person may be impeached are (art. ii., sec. 4) "treason, bribery, and other high crimes and misdemeanors." The constitution defines treason, but what acts are impeachable offences under the other words employed must be determined by the judgment of the two houses. They would probably be guided, but not governed, by the rules of the common law and the practice of parliament.—The method of procedure is substantially as follows: A resolution is offered by some member of the house, charging the party to be impeached with his supposed offence, and either demanding at once his impeachment, or, what is more common, providing for a committee of inquiry. If the resolution is passed, and if a committee of inquiry reports in favor of an impeachment, and their report is adopted, a committee (the same or another) is instructed to impeach the accused before the senate, and demand that that body make due provision for the trial, and inform the senate that articles of impeachment will be prepared by the house and exhibited before the senate. The same or another committee is intrusted to prepare articles of impeachment, which, being approved by the house, are transmitted to the senate by a committee appointed to conduct the trial on the part of the house, who are usually styled the managers of the impeachment. Due process

summoning the accused then issues from the senate, and is served by its sergeant-at-arms; and on the day therein appointed, the senate resolves itself into a court of impeachment, all the senators being sworn to do justice according to the constitution and the laws. The person thus impeached is then called upon to appear and answer. If he makes default, the senate proceeds *ex parte*. If he appears and denies the charges, and puts himself on trial (and he may appear by attorney), an issue is formed, and a time is appointed for the trial, which thereafter proceeds according to law and usage, and much in the same way as in common judicial trials. If any questions arise among the senators, who now act as judges, they are considered with closed doors, and are decided by yeas and nays, and only the decision is made public. Art. i., sec. 2, of the constitution of the United States, provides that no person shall be convicted without the concurrence of two thirds of the members. The most noted cases of impeachment in the United States are those of Judge Samuel Chase, of the federal supreme court (1804), and President Andrew Johnson (1868).

IMPHEE. See SORGHUM.

INACHUS, a mythical king, represented as the first ruler and priest of Argos, which, as well as the river Inachus, was often called after him. When Neptune and Juno contended for the possession of that country, he decided in favor of the latter, and thus incurred the anger of Neptune, who caused a dearth of water in his dominions. Several attempts have been made, even by the ancients, to explain the stories about Inachus; and it is considered probable that he was the leader of an Egyptian or Libyan colony which came across the sea and united with the Pelasgians.

INCAS. See PERU, and QUICHUAS.

INCENSE. See FRANKINCENSE.

INCEST, carnal commerce between a man and woman who are related to each other in any of the degrees within which marriage is prohibited by law. It rests with positive law to determine these degrees; for although marriages between those nearly related are clearly opposed to the law of nature, yet it is difficult to fix the point at which they cease to be so. With rare exceptions all civilized communities have agreed in regarding marriage between brother and sister and between those lineally related as unnatural and offensive; but beyond this point the invalidity must depend upon positive statutes. The fact that one of the parties is illegitimate is immaterial, as it is the nearness in blood that is regarded, and the repulsive nature of the relation is not diminished by the circumstance that the relationship comes through unlawful intercourse. Incest is a criminal offence in all civilized countries, and in England and the United States is punished as a felony.

INCHBALD, Elizabeth, an English dramatist, born at Standingfield, near Bury St. Edmund's,

Suffolk, Oct. 15, 1753, died in Kensington, Aug. 1, 1821. She was the daughter of a farmer named Simpson, who died when she was in her 18th year. She then sought an engagement at the London theatres, but without success. Recounting her troubles to Mr. Inchbald, a comedian of Drury Lane, much her senior, he married her, instructed her in the art, and performed with her for several seasons at London, Edinburgh, Glasgow, and elsewhere. He died in 1779, and she played successfully at Covent Garden from 1780 to 1789, when she retired from the boards and devoted herself to literature. In this new pursuit she was equally successful. She wrote 19 plays, and edited the "British Theatre," a collection of plays (47 vols., London, 1808-'15). A few of her own pieces, as "The Wedding Day" and "Wives as They Are," still hold their place on the English stage. Her novels, "A Simple Story" and "Nature and Art," once enjoyed even a higher popularity than her dramatic writings, and are still admired. She wrote an autobiography, which she caused to be destroyed. The "Memoirs of Mrs. Inchbald," by Boaden (2 vols. 8vo, London, 1833), was compiled from her journal, covering a period of 50 years.

INCLEDON, Benjamin Charles, an English singer, born at St. Keverne, Cornwall, in 1764, died in Worcester, Feb. 11, 1826. He acquired his earliest musical education in the choir of Exeter cathedral, and made his debut in London in 1790 in "The Poor Gentleman," with great success, and for 25 years remained unrivalled as a ballad singer. His voice was a fine tenor, and his favorite part upon the stage was Macheath. In 1817 he made a musical tour in the United States, but his voice was beginning to yield to age and irregular living, and the enterprise was not very successful.

INCUNABULA (Lat., cradle), in bibliography, books printed prior to about 1500, of which there are estimated to be about 15,000. The fullest account of them is found in Ludwig Hain's *Repertorium Bibliographicum, in quo Libri omnes ab Arte Typographica inventa usque ad Annum MD Typis expressi Ordine Alphabetico recensentur* (2 vols., Stuttgart, 1826-'38). For French incunabula see G. Brunet's *La France littéraire au XV^e siècle* (Paris, 1865).

INDEPENDENCE, a N. county of Arkansas, bounded E. by Black river, and traversed from N. W. to S. E. by White river; area, 1,050 sq. m.; pop. in 1870, 14,566, of whom 908 were colored. It has a very uneven surface, well wooded with pine and other timber. The soil is fertile. Black marble is found here. The chief productions in 1870 were 38,653 bushels of wheat, 508,005 of Indian corn, 30,820 of oats, 17,574 of Irish potatoes, 21,483 of sweet potatoes, 21,336 lbs. of tobacco, 139,225 of butter, and 5,613 bales of cotton. There were 3,370 horses, 4,059 milch cows, 1,496 working oxen, 5,677 other cattle, 5,387 sheep, 22,787 swine, and 8 flour mills. Capital, Batesville.

INDEPENDENCE. I. A town of Washington co., Texas, 80 m. E. of Austin, 18 m. from Navasota on the Houston and Texas Central railroad, and 12 m. from Brenham on the W. branch of that line; pop. about 1,000. It is pleasantly situated in the midst of diversified scenery, and contains several public schools, and Baptist, Episcopal, and Methodist churches. It is the seat of Baylor university, chartered in 1845, and Baylor female college, under the control of the Baptists. The university had at first a collegiate and a law department (at present suspended); in 1866 a theological department was added. In 1873-'4 it had 5 professors, 2 assistants, 80 students (11 theological), and a library of 2,700 volumes. II. A city and the capital of Buchanan co., Iowa, on the Wapsipinicon river, and at the intersection of the Iowa division of the Illinois Central railroad with the Milwaukee division of the Burlington, Cedar Rapids, and Minnesota line, 107 m. N. E. of Des Moines; pop. in 1870, 2,945. It contains a national bank, 10 public schools, including two high schools, two weekly newspapers, and eight churches. It is the seat of one of the state insane hospitals, recently established, which in November, 1873, had 113 patients. The building, when completed, will accommodate 500. III. A city and the capital of Jackson co., Missouri, on the Missouri Pacific railroad, 10 m. from Kansas City, 4 m. S. of the Missouri river, and 130 m. W. N. W. of Jefferson City; pop. in 1870, 3,184. It contains a national bank, three hotels, three public schools, including a high school, two colleges, and two weekly newspapers. It was settled in 1827, and formerly derived great importance from its position as an entrepot between New Mexico and Utah and the eastern states, and a place of outfit for emigrant trains to Oregon and California. The Mormons settled there in 1837, but were expelled, and took refuge in Illinois and afterward in Utah. Members of one branch of the church have purchased the grounds designed by Joseph Smith as the site of the grand temple, and intend to erect the edifice at an early day. They are assembling here quite rapidly.

INDEPENDENTS, a Protestant sect which arose in England in the 16th century. The Puritan element, which began to appear within the Anglican church so early as the reign of Henry VIII. and of Edward VI., gave rise in Mary's reign to secret dissenting congregations, essentially independent in church organization and government. Although in one or two instances there are earlier traces of separate congregations, the first open movement toward local churches distinct from the established church was under the leadership of Robert Brown, about 1586. At first they were called Brownists; but their discipline having been modified by John Robinson and Henry Jacob, who had been connected with him, they took the name of Independents, and rapidly spread over England. From Holland a body of them carried

their tenets to America in 1620. They flourished in England during the commonwealth, Cromwell himself being in their communion; but on the restoration the act of uniformity, passed in 1662, excluded 1,900 of their ministers from office. The act of toleration, 1689, freed dissenters from the pains and penalties imposed on the exercise of their worship, and in 1691 a temporary union was effected between the English Presbyterians and Independents. It was not, however, till the repeal of the test and corporation acts in 1828 that the English Independents, with other dissenters, were freed from all civil disabilities. Robinson, under whom they were called Independents, is generally esteemed the father of modern Congregationalism. In their subsequent history the Independents in England and the Congregationalists in America have held practically the same ecclesiastical views. Thus the Independent churches of England formed a Congregational union in 1831, and an article of their constitution formally recognizes the fellowship of the churches. Less use of councils is made, however, than by the Congregationalists in America. The name Independent is sometimes used in ecclesiastical discussion to designate those Congregationalists who incline toward the principles of independency.—In Scotland there is a body called New Independents. It originated in a separation from the church of Scotland about the end of the last century, under the lead of Robert and James Haldane, from whom its members were called Haldanites. Large places of public worship were erected at Robert Haldane's expense in several towns, and academies for the education of preachers were established in Edinburgh, Dundee, and Glasgow. The New Independents increased rapidly, and in the beginning of the present century had 86 churches; they have at present about 120. They utterly reject any connection of church and state, and make little distinction between the laity and clergy, considering it not irregular that a layman, in the absence of a clergyman, should administer the Lord's supper, which they celebrate weekly. In other respects they differ little in doctrine or worship from other Independents. (See CONGREGATIONALISM.)

INDEX LIBRORUM, a catalogue of books censured by the supreme authority in the Roman Catholic church as prejudicial to faith and good morals. This catalogue is twofold: that of books absolutely forbidden to be read, *Index Librorum Prohibitorum*; and that of books forbidden only until they are expurgated or corrected by their author, *Index Librorum Expurgandorum*. It is published by the "Congregation of the Index," composed of cardinals designated by the pope, with a secretary, who is by right a Dominican monk, and a body of examining theologians, usually belonging to the other religious orders, and called the *consultum*. To the *consultum* are submitted the suspected books, and they report back to the cardinals,

who hold their deliberations either in presence of the pope, or in the house of the senior cardinal of their number. All books that treat *ex professo* of faith or morals, of ecclesiastical discipline, or of civil society, fall within their jurisdiction; and the judgment of the congregation either suppresses the book altogether, or commands it to be corrected, or permits it to be read under certain conditions, or by a certain class of persons only. The first official index or catalogue was prepared by the inquisition at Rome, and published in 1557 by order of Pope Paul IV. This, enlarged and reduced to a regular form by a committee of the council of Trent, was published anew in 1564, with the sanction of Pius IV., and enlarged by Clement VIII. in 1595. The latest official edition is that of 1819. The index is continually enlarged by the supplementary lists of each year. The congregation of the index originated with the council of Trent under Pius IV., and its official establishment is due to Pius V.

INDIA, or Hindostan (*Hindu*, and *stan* or *sthan*, settled habitation), a country of Asia, consisting in the widest sense of the great southern peninsula of that continent, and the adjacent territories S. of the Himalaya mountains and W. of Burma and Siam, and forming the richest and most populous foreign dependency of Great Britain. It is situated between lat. 8° and 35° N. (or 36° 30' if Cashmere is included), and lon. 66° 30' and 99° E., and is bounded N. by Chinese Turkistan and Thibet, from which it is separated by the Himalaya range, E. by Burma and Siam, and W. by Beloochistan and Afghanistan. The entire coast of the country E. of Cape Comorin, the southern extremity of the peninsula, is washed by the bay of Bengal, while the S. W. coast extends along the Indian ocean and the Arabian sea. The extent of coast line is upward of 4,000 m. in all, of which more than half is on the bay of Bengal. The extreme length of India from N. to S. is about 1,900 m., and its extreme breadth from E. to W., exclusive of British Burma, about 1,700 m. According to Dr. W. W. Hunter, director general of statistics to the government of India, the empire and its feudatory states embrace a territory of 1,556,836 sq. m., with a population of not less than 200,000,000. The country is naturally divided into several great regions. In the north are the extensive depressed river basins of the Indus and the Ganges. The central portion is occupied by a diamond-shaped table land having its greatest length from N. to S. An elevated wedge-like district forms the termination of the peninsula, sloping from its centre to the E. and W. coasts, and southward to Cape Comorin. The Vindhya mountains stretch across the central plateau from near the W. coast, in lat. 22° 10', to the Ganges valley near lat. 25°. N. of this range is the northern portion of the diamond-shaped table land. Its apex is in the vicinity of Delhi; the Aravulli mountains, an offshoot of the Vindhya, bound it on the west, and its N. E. margin is

parallel with the Ganges. The Vindhya range and its continuations to the Rajmahal hills, where the Ganges turns southward toward the delta, form the northern boundary of the southern part of the central table land. It is fringed on the west by the Western Ghats and on the east by the lower Eastern Ghats, the two ranges converging at the south in the Neilgherry hills, long supposed to be the highest mountain mass S. of the Himalaya. A peak in the Animalley hills, further S., is now known to be 8,837 ft. above the level of the sea, higher than Mt. Dodabetta, the loftiest summit of the Neilgherries. The Western Ghats rise from 3,000 to upward of 5,000 ft. (in some parts to 7,000 ft.), but the Eastern Ghats rarely exceed 3,000 ft. A more detailed examination of the physical configuration of India presents the following clearly defined geographical divisions: 1. The Himalaya mountains, fully treated under their own title. 2. The plain of the Indus, which comprises the Punjab, or fan-shaped "country of the five rivers," Jhylum, Chenaub, Ravee, Beas, and Sutlej; the great Indian desert; and the valley of Sinde. The Suleiman and Hala mountains separate this region from Afghanistan and Beloochistan. The general surface of the Punjab slopes southward from the Himalaya range. In the north is a narrow but well watered agricultural belt of great fertility; to this succeeds a region where rain is less plentiful, and where cultivation is confined to the valleys, from 4 to 10 m. in width, which the rivers have worn down below the level of the adjacent sterile country, to depths of from 10 to 50 ft. The alluvial plain of Sinde is arid, rainless, and absolutely unproductive without artificial irrigation. It is bordered on the east by the great desert, frequently termed the Thurr, a formation of hard clay overspread with shifting sand, which extends to the basin of the Ganges, being itself bounded S. E. by the Aravulli mountains. The principal countries of the plain of the Indus are: the province of the Punjab, which includes the former kingdom of Lahore; the native state of Bhawalpoor; the western portion of Rajpootana; and the commissionership of Sinde, under the Bombay government. 3. The plain of the Ganges, which, together with all central India nearly as far S. as the Nerbudda river, constitutes Hindostan proper, the name not having been applied originally to the whole country. This region is densely populated, teems with fertility, and is especially rich in historical interest. On the east the basin of the Ganges unites with that of the Brahmappootra, beyond which rise the Cossyah and Garrow hills and the Burmese mountains. The slope of the Gangetic plain from the base of the Himalayas to the bay of Bengal is very gentle, not greatly exceeding 1,000 ft. of descent. The British administrative divisions of this part of India are: the Northwest Provinces, in which is the territory known as Rohilcund; Oude; and Bengal, of which the garden-like state of Behar forms

the western portion. 4. The highlands of central India. In the most extensive sense these comprehend the whole of the interior plateau not included in the Deccan. On the northern slope is the table land of Malwa, with an elevation of from 1,300 to 2,000 ft. above the sea. It is occupied by a number of principalities ruled by native chiefs, under the supervision of the British government. On the W. side are Guzerat and Cutch. A part of Rajpootana falls within this geographical division. The territory, which owes its name to the former rule of Rajpoot princes over most of it, consists of 18 separate subject-allied states of various dimensions, with a collective area estimated at 80,000 sq. m., and about 8,500,000 inhabitants. Strictly speaking, the Nerbudda valley is the northern limit of the Deccan; but the region comprising the Satpoora hills, S. of the river, and lying between lon. 76° and 82° E. along the 22d parallel, is generally regarded as belonging to the highlands of central India. Here culminates the elevated ridge which has been referred to as crossing the peninsula, in peaks nearly 5,000 ft. high, rising above numerous lower plateaus and flat-topped hills, below which lies the general surface of the plain, which has an elevation of about 1,000 ft. above the sea. In this section are the head waters of the Sone, which flows into the Ganges, of the Mahanuddy, running directly into the bay of Bengal, and of the parallel westward-flowing Nerbudda and Taptee. There is also a southern drainage into the Godavery. The country was anciently called Gondwana, from the Gonds, its aboriginal inhabitants. It is now incorporated politically within 11 of the 19 administrative districts of the Central Provinces. 5. The Deccan, a term originally applied to the whole peninsula of India S. of the Nerbudda river, but now restricted to the country extending from the Nerbudda on the north to the Kistnah on the south, or from near lat. 23° to 16° N. It consists chiefly of an elevated table land, enclosed by low plains, extending to the seashore, the E. and W. Ghauts forming its buttresses. This table land extends beyond the Kistnah to the Neilgherries, and gradually increases in height, as it trends southward, from 1,500 to 2,000 ft. in Hyderabad to 4,000 ft. in Mysore. Its principal rivers are the Godavery, draining an area of 92,800 sq. m., the Kistnah, with a drainage basin of 81,000 sq. m., and the Mahanuddy. These, as well as the Cavery, which waters Mysore, flow to the S. E. coast. The centre of the N. portion of the Deccan is occupied by the territories of the nizam or rajah of Hyderabad, a Mohammedan prince whose dominions were formerly called the kingdom of Golconda, from the city of that name, famous for its traffic in diamonds. The rest of the Deccan, with inconsiderable exceptions, is subject directly to British rule, under the governments of Madras and Bombay; while Mysore is now administered as a British province. The narrow strip of land which

lies between the Western Ghauts and the Indian ocean is called the Malabar coast, but the name properly belongs only to the portion S. of Canara. The opposite coast of the peninsula, on the bay of Bengal, is called Coromandel. All the eastern part of the peninsula between the Kistnah and the southern boundary of Mysore is called the Carnatic. 6. The triangular block in which India terminates at the south. Here the Palnai hills confront the Neilgherries, and like them overlook the gap of Coimbatore, which separates the two ranges. Extensions of the Eastern and Western Ghauts stretch southward nearly to Cape Comorin. Cochin and Travancore are subject-allied territories in the west; the rest of the region is a part of the Madras presidency. The entire tract is fertile, well wooded, and abundantly supplied with water. 7. British Burmah, described under its own title, is a province geographically distinct from the rest of India.—For purposes of political administration under British rule, India was long divided into the three presidencies of Fort William in Bengal, Madras, and Bombay; but this mode of division has been abandoned. The following table shows the existing arrangement of provinces, and the area and population of each, according to the official statement furnished to parliament by the secretary of state for India in 1873. In the case of Bengal, the area is exclusive of waste and forest lands and great rivers; and the Bannu district is not included in the area of the Punjab:

DIVISIONS.	Date of census.	Area in sq. miles.	Population.
Bengal.....	1872	230,892	66,856,859
N ^W thwest Provinces..	1872	50,901	30,769,056
Oude.....	1869	23,973	11,220,747
Punjab.....	1872	101,752	17,611,498
Central Provinces...	1872	64,162	9,066,088
Benar.....	1867	16,900	2,231,565
British Burmah.....	1871-'2	98,664	2,562,323
Madras.....	1872	141,746	31,311,142
Mysore.....	1872	27,077	5,055,412
Coorg.....	1872	2,000	168,312
Bombay.....	1872	127,532	14,042,596
Total British India.....		930,599	190,895,548
Native states.....		646,147	46,245,888
Total.....		1,576,746	237,141,436

The statistics as to British Burmah are merely estimates from the administration report of that province for 1871-'2. A census was taken there in 1872, but its results have not yet been published. Bengal proper, Behar, Orissa, Assam, and Chota Nagpore make up the present province of Bengal, and together with the Northwest Provinces formerly constituted the presidency of Fort William in Bengal. Mysore and Coorg are under one provincial administration. The chief executive authority of the Indian government is the governor general, or viceroy, who is appointed by the crown, and receives a salary of £25,000 per annum, besides allowances. He acts under the direction of the secretary of state for India, a member of the

British ministry, who is assisted by a council of 15 persons, 9 of whom must have had at least 10 years' experience in India. Originally 7 of these councillors were appointed by the East India company, but the secretary of state for India has the power to fill future vacancies. Their term of office is 10 years. The law-making power is vested in the governor general in council. The seat of government is at Calcutta. The governors of Madras and Bombay are appointed directly by the crown, but the lieutenant governors and commissioners of the other provinces are appointed by the viceroy subject to the approval of the crown. The governor general's council consists of five ordinary members, and the commander-in-chief of the army as an extraordinary member. The military force maintained by the British government in India in 1872 numbered 190,264 men, of whom, exclusive of officers, 60,632 were English, stationed chiefly in the Punjab and along the valley of the Ganges. All appointments to the civil service are made upon competitive examination. The district is the unit of the general civil administration of the British in India. The districts vary greatly in area and population, as, for example, from 1,200 to 12,000 sq. m., and from 500,000 to 1,000,000 inhabitants. The chief government official in each district is the collector and magistrate. He receives the revenue, is intrusted with magisterial powers and certain judicial functions, and is generally responsible for the public welfare. He is usually aided by several deputies and assistants. The highest judicial authority in the district is vested in the district judge, who exercises original jurisdiction in criminal cases, reviews the judicial determinations of the collector and magistrate, and hears appeals from the numerous civil courts held by native judges. There are high courts at Calcutta, Bombay, and Madras, with general appellate jurisdiction, special powers concerning cases affecting Europeans, and original local jurisdiction. A code of criminal procedure regulates the administration of the laws relating to offences.—With the exception of Nepal and Bootan in the north, the native states of India are all more or less subject to British control or interference. Estimates of the area and population of these states appear in the following table:

NATIVE STATES UNDER	Area in sq. m.	Population.
Government of India.....	385,296	27,716,352
“ Bengal.....	79,156	2,189,565
“ N'west Provinces	5,890	1,284,691
“ Punjab.....	43,877	5,086,502
“ Central Provinces.	23,399	1,095,275
“ Madras.....	31,953	2,371,333
“ Bombay.....	72,076	6,552,170
Total native states.....	646,147	46,245,888

In the north, British supremacy is acknowledged in Cashmere, although that country is not included in the above estimates. Bhawalpoor is

the next in importance of the states supervised by the Punjab government, which also superintends the Sikh districts lying between the Sutlej and the Jumna. Further S. is Rajpootana, the agent for which resides at Ajmeer, in the small British district of that name, in the centre of the country. The native states of central India form what is called the Indore agency. Among them are Gwalior, Bhopal, and the Mahratta country. Guzerat, Cattywar, and Cutch are under the Bombay administration. In the Deccan, the chief dependency is Hyderabad. The Madras government presides over Cochin and Travancore in the extreme south. The French possess Pondicherry and Carical on the Coromandel coast, and Mahé on the Malabar coast, as well as the town of Chandernagore, 17 m. N. of Calcutta; but the aggregate area of the French colonial possessions in India is estimated at only 196 sq. m., and the population at about 260,000. The territory of Goa, on the Bombay coast, Damaun, a seaport of North Concan, and Diu island off the southern coast of Cattywar, are colonies of Portugal. Goa has an area of about 1,000 sq. m. and contains about 418,000 inhabitants.—The principal mountains and rivers of India have been referred to in the general description of the country. The respective lengths of the chief rivers are: the Indus, 1,960 m.; the Ganges and Brahmapootra each over 1,500 m., if the latter be regarded as including the Sanpo; Jumna, a tributary of the Ganges, 800; Sutlej, a branch of the Indus, 900; Chenaub, a tributary of the Indus, 750; Gunduck, a branch of the Ganges, 400; Godavery, 900; Kistnah, 800; Nerbudda, 800; Mahanuddy, 550; Cavery, 470; and Taptee, 450. India, considering its great extent, is singularly deficient in lakes. In the province of Orissa is the Chilka lake, 44 m. long and from 5 to 20 m. broad; and on the Coromandel coast is the Pulicat lake, 33 m. long and 11 m. broad. These, however, are salt, and are in fact little more than lagoons formed by the sea breaking over the low sandy shore. There are a few other lakes, but none of much size.—The climate of India varies from that of the temperate zone in the Himalaya to the tropical heat of the lowlands. On the central and southern table lands the climate is comparatively mild, the thermometer falling as low as the freezing point in winter; but on the great plains which contain the principal cities and the bulk of the population the heat during the greater part of the year is excessive, the thermometer frequently rising to 100° and 110° F. A marked influence is exercised on the climate and seasons of Hindostan by the winds called monsoons, which blow half the year from the S. W. and the other half from the N. E. The S. W. monsoon begins in the south of Hindostan early in June, and in the north somewhat later. It brings with it from the Indian ocean floods of rain, which continues to fall at intervals until the end of September. During this rainy

season the fall of rain is in Bengal from 50 to 80 in. The N. E. monsoon begins about the middle of October, and brings rain from the bay of Bengal, which falls in torrents on the Coromandel coast until the middle or end of December, during which period the opposite coast of the peninsula enjoys fair weather and northerly breezes. From December to June is the dry season, during which little rain falls.—The great plain of the Ganges is a rich, black, alluvial mould. In some parts of Bengal extensive tracts of clayey soil are found. In the Punjab a black fertile soil prevails, which to the southwest in Sindh and Guzerat becomes sandy. On the table land of Malwa the soil is a deep, rich, black mould. On the great northern table land it is generally a fertile loam on a substratum of rock. On the Malabar coast a red clay soil is found. On the Coromandel coast the soil is mostly sandy from the sea to the foot of the Ghauts. A complete geological survey of India was commenced 22 years ago, and is still in progress. Coal, iron, and salt are the most important and abundant mineral products. The principal coal fields are in the valley of the river Damooda, N. W. of Calcutta, where they occupy an area of 1,500 sq. m. Of 497,000 tons of coal mined in India in 1868, 493,000 tons were obtained from the Raniganj bed in this district. Other coal-bearing localities are Chota Nagpore, South Rewah, and the upper Sone valley, where seams are known to exist, although they have never been thoroughly explored; the Nerbudda valley and the Satpura hills in central India; and the sandstone region which forms the basin of the Godavery and its affluents the Pranhita and Wurdah. Coal of good quality is also found in the Cossyah hills, and in the wild and densely timbered tracts of eastern Assam. The average proportion of fixed carbon in Indian coal is 52 per cent., and there is from 10 to 30 per cent. of ash. Iron is widely distributed throughout the country, the sources of supply being red hematite, magnetic, specular, and clay ores, and surface deposits. It has been manufactured in India for centuries. Salt is procured, in immense quantities and of remarkable purity, from the salt range of the Punjab. In India the amount of salt consumed bears a greater proportion to other articles of food than in any other country in the world. Gold is found in the gravel of streams, but only in small quantities. It occurs in the north-western Himalaya districts, where silver associated with lead is also found, and in Chota Nagpore, Assam, the valley of the Godavery, and many other parts. Lead is obtained from the same portion of the Himalaya, and there is a considerable yield of copper in Gurwhal, Nepal, and Sikkim, and near Singbloom in Bengal. Antimony occurs abundantly in northern India, and cobalt in small quantities near Jeypoor in Rajpootana. There are valuable tin mines in British Burmah, and petroleum has been discovered in the Pegu dis-

trict of that province, as well as in some parts of the Punjab. Among the gems found in India are the diamond, ruby, topaz, beryl, carnelian, and garnet. The yield of Indian diamonds has largely diminished, but some are still obtained in the Central Provinces and in southern India. Beautiful agates are exported from Guzerat.—The characteristics of Indian vegetation vary with the zones of elevation. The flora of the mountain region of the north corresponds closely with that of Europe. This section is the home of the pine and other conifers. No species of pine is native to the peninsula, but on the mountains of British Burmah grow forests of the *pinus Khasiana*. Along the foot of the Himalaya range from Sikkim to Assam is found the *ficus elastica*, which yields caoutchouc. Below the coniferous forests are tracts of bamboo, whence millions of bamboos are annually exported down the Ganges. Here also grows the saul (*shorea robusta*), second in value only to the teak among the timber trees of India. There are extensive teak forests on the trap formations of the highlands of central India. In Sindh and the Punjab, the babul (*acacia Arabica*) and a leafless caper shrub (*capparis aphylla*) cover broad belts of country. A large proportion of the timber growth of the Northwest Provinces consists of the deodar tree, from which railway sleepers are made. The sissu is another important Indian timber tree. There are plantations of sandalwood in Mysore, and the valuable ironwood tree occurs in the Burmese commissionership of Aracan. The Indian government maintains a thorough system of forest conservancy. Among the characteristic forms of vegetation are the celebrated banian tree and the sacred peepul (*ficus religiosa*). The palm family is represented by the coconut and betelnut. Rice is the staple cereal production of the plains, which also yield cotton, sugar cane, indigo, jute, and opium. Maize, millet, peas, beans, and many varieties of grain peculiar to the country are also raised. Wheat and barley are cultivated on the higher grounds. There are extensive tea gardens in Assam and the mountainous districts of the north, and the cultivation of coffee is carried on among the hills of southern India. The cinchona plant was introduced into India from South America in 1860, and has been grown with great success among the Neilgherries, and in other sections. Pepper is produced in Malabar. The fruits of the temperate zone are found in the elevated regions, while those of the tropics, prominent among which is the mango, grow in the lower and warmer parts of the country.—In the geographical distribution of animals, the fauna of India belongs to the zoological province including southern Asia and the western portion of the Indian archipelago. Ten species of *felidæ* are found S. of the Himalaya, including the lion, tiger, leopard, cheetah, and the true cats (*F. catus*). The Indian lion is characterized by a very short mane. Of all

mammals, the so-called royal or Bengal tiger is the most destructive to human life. The Asiatic elephant (*E. Indicus*) is captured for purposes of domestication; the tame animals will not breed, so that the supply has to be kept up from the forests. There are two species of rhinoceros whose range includes India, both single-horned. Of these the larger (*R. Indicus*) is met with at the foot of the Himalaya and in Assam; the smaller (*R. Sondaicus*) was formerly called the Javan rhinoceros, but is now known to frequent the mainland, extending into western Bengal. The dromedary is enumerated by Blyth in his catalogue of Indian mammals; the Bactrian camel has been introduced. Two genera of four-horned antelopes occur in the Sivalik hills. Several species of deer are met with. Most of the Indian monkeys belong to the genus *semnopithecus*, having a long tail, which, however, is not prehensile. The sacred monkey of the Hindoos (*S. entellus*) is the species best known. Bears, wild boars, foxes, and squirrels are numerous, and hares and porcupines abound. The Indian hyæna is the striped species, and, like the jackal, is very common. The buffalo is found wild throughout the peninsula, and is also domesticated; other domestic animals are the horse, the ass, the yak, and the goat. Frugivorous, insectivorous, and leaf-nosed bats are all denizens of India. Many of the birds of the country are distinguished by the most gorgeous plumage; such are the various species of cuckoos and parrots, the kingfishers, and the pigeons. Among the birds of prey we find eagles, falcons, hawks, and vultures; and among the waders are cranes, herons, and storks. Crows and owls are numerous in many districts. The gallinaceous birds are represented by partridges, pheasants, quails, wild peacocks, and the common domestic fowls of Europe and America, which originally were derived from southern Asia. India abounds in dangerous reptiles. Nearly 150 species of snakes inhabit the peninsula, many of which are fatally venomous. Those most dreaded are the celebrated cobra de capello; the hamadryad (*ophiophagus elaps*), a hooded tree snake; the krait (*bungarus caruleus*); and the daboia (*vipera Russellii*), known in Ceylon as the *tic polonga*. In 1869, 14,529 persons lost their lives in India in consequence of snake bites; and in 1871 the total number of deaths known to have been caused by dangerous animals of all kinds was 18,078. Crocodiles haunt the rivers in great numbers, and in many districts tortoises and turtles are plentiful. The rivers swarm with fish, which form a large part of the food of the people in Orissa and other portions of Bengal, British Burmah, the Northwest Provinces, the Punjab, and Canara. The varieties of insects are innumerable.—The most remarkable feature in the social life of India is the Hindoo institution of caste, for an account of which see INDIA, RELIGIONS AND RELIGIOUS LITERATURE OF. The condition of the people is as various

as are the different regions they inhabit. For the most part they are comfortably housed. The system of townships or villages has prevailed for ages, and has survived through innumerable revolutions and conquests. Each township manages its own internal affairs, levies upon its members the taxes demanded by the state, organizes its own police, and is responsible for all property taken by thieves within its limits. It administers justice to its own members, punishing small offences and deciding petty lawsuits. It also keeps in repair the roads and public edifices, and provides for the maintenance of public worship and the support of the poor. For all these duties it provides the proper officers, who are paid by fees, sometimes in money, but more often in produce. Cultivation is laboriously though not very skillfully pursued by the natives, whose implements are usually of a rude kind. Manure is little employed, as the bulk of the people use little or no animal food and keep scarcely any stock. The religious prejudices of the people also prevent them from using as manure the dung of cattle, which is considered holy and devoted to religious purposes. The climate and sanitary condition of India make the country peculiarly subject to pestilence and famine; bad water and bad drainage give rise to disease, and the ravages of the periodical epidemics are aggravated by the immense congregations of people on long pilgrimages. Medical dispensaries and hospitals have been established by the government in most of the provinces. Civil order is maintained by a police force of about 190,000 constables, in addition to the watchmen of the village communities. The inhabitants of India are the most litigious people in the world; 1,088,153 civil suits were pending in the country in 1871-'2.—In none of the fine arts except architecture have the Hindoos attained much eminence. Their paintings are of very little merit, though the walls of temples, of palaces, and of the better class of private dwellings are often ornamented at great cost with pictures illustrating the characters and events of their mythology. More attention has been paid to sculpture than to painting, and in the temples cut from the living rock great numbers of statues are contained, some single figures and others large groups. Many of these are bold and spirited in design, though the human form is not exhibited in good proportion or with its parts well developed. In many districts of India splendid monuments of architecture abound, mostly the work of past ages, and many of remote antiquity. Such are the Jain temples at Ajmeer and elsewhere, some of which were built long before the Christian era, and are distinguished not only for size and splendor of ornamentation, but for symmetry, beauty of proportion, and refinement of taste. The mosques, palaces, and tombs erected by the Mohammedan emperors are the finest specimens in the world of the Saracenic style of architecture. Those at

Agra, Delhi, and Lucknow are especially remarkable for their delicacy, beauty, and taste. The most wonderful structures in the country are perhaps the great rock temples in the western part of the Deccan, and those near Bombay. (See ELEPHANTA, and ELLORA).—Among the most important cities of India are Calcutta, the capital, on the Hoogly, in Bengal; Bombay, the chief seaport on the W. coast; Madras, on the Coromandel coast; Benares, the holy city of the Hindoos, in the Northwest Provinces, on the banks of the Ganges; Patna, an important centre of the opium trade in Behar; Allahabad, at the confluence of the Ganges and the Jumna; Lucknow, the capital of Oude; Delhi, the metropolis of the Mohammedan empire in India; Lahore and Amritsir, in the Punjab; Baroda, in Guzerat; Poona, in the territory of Bombay; Nagpore, in the heart of central India; and Hyderabad, the capital of the Nizam's Dominions. Almost all of these cities contain upward of 100,000 inhabitants, as do also Agra, Ahmedabad, Bangalore, and several others.—A vast network of railways, constructed by the British, is rapidly overspreading the entire land. Lines are already completed running up the Gangetic valley from Calcutta to Allahabad and Delhi, with a continuation to Lahore, and a branch to Lucknow; from Bombay to Allahabad, thus connecting the former city with Calcutta; also from Bombay northward to Baroda, and southward across the peninsula to Madras. Many other lines are in progress of construction. In 1873, 5,478 $\frac{3}{4}$ m. of railway were in operation. Telegraph lines, with an aggregate length of 15,102 m. in 1871, connect all the important places in India. There are three routes of telegraphic communication with England: one consisting of land lines from Constantinople to Bagdad, and thence to Fao at the head of the Persian gulf, whence a submarine cable leads to the port of Kurrachee near the mouths of the Indus; a second, by means of the same cable to Bushire, which is one of its repeating stations, and thence to the European system by way of Teheran, Tiflis, and Kertch; and the third being the submarine cable between Suez and Bombay. A submarine cable also extends from Madras to Singapore, and the latter port is similarly connected with Hong Kong. The chief public works of native construction are reservoirs or tanks for purposes of irrigation, which exist in immense numbers and frequently of great size and cost, being often magnificently built of stone. There are also a number of canals constructed by the native princes in former ages, but these have mostly fallen into neglect and disuse. The British government has conducted an extensive and systematic course of internal improvement. Immense canals, inferior to none in the world, have been constructed, the chief of which are those of the Jumna and the Ganges, to facilitate not only irrigation but the navigation of those rivers. These great systems of irriga-

tion comprehend not only the upper portion of the Ganges basin, but the valley of the Indus, and districts in Orissa, Madras, Bombay, and other parts of the country.—Silk, cotton, and woollen goods are the leading manufactures of India. Sericulture is extensively carried on in Bengal and Mysore, and both these provinces are the seats of silk manufacture. Delhi is celebrated for its silk embroideries, and Benares and Ahmedabad for their gold brocades. The manufactures of the Punjab comprise silks, woollens, and white and colored cotton goods, the estimated value of the annual production being £4,850,000. Cotton is also manufactured in Oude, the Central Provinces, and Mysore. In the latter country there are cutlery works and manufactories of gold and silver lace. As the great bulk of the products is consumed in the country itself, the internal trade is very large, but there are only meagre statistics concerning it. Silver is the standard of value, and the monetary unit is the rupee, which is worth about two shillings sterling. The foreign trade of India has for centuries been famous for its lucrative nature. There were said to be 1,230 square-rigged vessels, 948 steamers, and over 50,000 native craft engaged in its carriage in 1871-'2. In that year the values of some of the principal exports were as follows: coffee, £1,380,409; cotton, £21,272,430; grains, including rice, £4,865,748; indigo, £3,705,475; jute, £4,117,308; opium, £13,365,228; seeds, £2,728,127; tea, £1,482,185; and wool, £906,699. The chief articles imported in the same year were: cotton twist and yarn, £2,473,353; cotton piece goods, £15,009,981; machinery, £405,835; manufactured metals, £925,839; raw metals, £1,464,936; railway materials and stores, £516,996; salt, £913,915; raw silk, £651,595; silk goods, £480,948; wines and liquors, £1,381,961. Of gold and silver £11,573,813 were imported in 1871-'2, and £1,476,093 exported, leaving a balance of £10,097,720 remaining in India. This flow of the precious metals into India has for ages been a remarkable feature of the commerce of that country. A considerable foreign traffic, amounting to more than £1,000,000 in value annually, is carried on over the Himalayan passes, with Afghanistan, Turkistan, and Tibet.—The main sources of government revenue are the land tax, opium sales, salt duties, customs, and excise and stamp tax. More than two fifths of the receipts are derived from the land settlements. The terms of these vary in different provinces, but the principle generally sought to be applied is that the government is entitled to receive a certain proportion of the net produce of the land. Three modes of settlement are in vogue: the zemindary, in which proprietors known as zemindars are responsible for the assessments of given districts, thus standing in the position of landlords themselves; the village system, in which the villagers hold the land collectively as toward the government; and the ryotwar system, in

which the individual cultivators, known as ryots, pay assessments directly to the government. Bengal is for the most part subject to a permanent settlement made on a fixed basis for ever with the zemindars in 1793; so that the land revenue of Bengal proper, Behar, and Orissa yields but little more now than it did then. Generally throughout the rest of the country, however, the government demand is a certain percentage of an assumed rental, which rental is fixed for a term of years, quite commonly 30. In northern India the tenure by village communities prevails, but Madras and Bombay are subject to the ryotwar system. The government has a monopoly of the opium grown in Bengal, which it buys of the cultivator at a fixed price, and sells in the following year. A heavy duty is levied on Malwa opium, which can be legally exported only through the port of Bombay. There is a duty on imported salt in Bengal, a government salt monopoly in Madras, and an excise on the salt works in Bombay. In the year ending March 31, 1872, the revenue included £20,520,337 from land, £9,253,859 from opium, £5,966,595 from salt, £2,575,990 from customs, £2,369,109 from excise on spirits and drugs, and £2,476,333 from stamps. The total ordinary revenue of the Indian government for that year was £50,110,215, and the total ordinary expenditure £46,986,038. For 1872-'3 the revenue was £50,220,360, and the total expenditure was £50,641,052, of which £2,184,570 was extraordinary expenditure for public works. Excluding the latter item, there was a surplus of £1,763,878; including it, the deficit for the year amounted to £420,692. The regular estimates for 1873-'4 were as follows: Revenue, £49,476,000; ordinary expenditure, £51,577,300, which included £3,920,000 for the relief of the famine in Bengal; extraordinary expenditure upon public works, £3,541,000; total expenditure, £55,118,300; surplus, excluding expenditures on account of the famine and for public works, £1,818,700; deficit, excluding expenditure for public works, £2,101,300; deficit, including it, £5,642,300. The preliminary estimates of the governor general for the fiscal year 1874-'5 show a revenue of £48,984,000 and a total expenditure of £54,935,000, thus leaving a deficit of £5,951,000. The expenditure comprises £2,580,000 for famine relief, and £4,563,000 for public works; if these items were excluded, there would be a surplus of £1,192,000. The deficit would be reduced to £1,388,000 if the amount laid out on public works were excluded from the total expenditure.—A well graded system of education, providing instruction for all classes, has been in process of organization and development in India since 1854. There are three universities, at Calcutta, Madras, and Bombay respectively. With each of these is affiliated a certain number of colleges, which fit the university undergraduates for the higher examinations; and next below in the scale are the

high schools where students are prepared to enter the university. These institutions complete the scheme for the education of the wealthier classes. After them come the middle schools, where the course of instruction is intermediate between that of the primary and the high schools. Elementary education is afforded by the primary or village schools, of which the several provinces contain 37,544, there being 9,701 in receipt of government aid. Of colleges there are 28 in Bengal, 7 in the Northwest Provinces, 1 in Oude, 3 in the Punjab, 13 in Madras, and 8 in Bombay. The total number of high schools is 349, of middle schools 3,096, of female schools 2,011, and of normal schools 132. The professional schools comprise civil engineering colleges at Roorkee, Calcutta, Madras, and Poonah; medical colleges at Bombay, Madras, Lahore, and Calcutta (the attendance of students at the last in 1871-'2 numbering 1,046 persons); and schools of design and decorative art at Calcutta and Madras. There are museums in many of the principal cities. From the outset it has been the object of the Indian educational system, while encouraging the cultivation of the English language, to diffuse a knowledge of European science, art, and philosophy by means of the native languages. There is an influential native press, and several hundreds of books in various tongues are published annually. Scientific and literary societies, including both Europeans and natives in their membership, flourish in many of the cities. Prominent among them is the Bengal Asiatic society at Calcutta, founded in 1784 by Sir William Jones.—Of the earliest period of the history of India little is known with certainty. The sacred writings of the Hindoos give to their ancient history an incredible chronology, extending over millions of years, and treat of heroes, kings, and dynasties, in most instances probably merely mythical or fabulous. It is the general opinion of the best authorities that the Hindoos were not the first inhabitants of the country, but were an invading race who subdued and enslaved the aborigines, who are still represented by rude tribes in the central and southern parts of India, such as the Bheels, the Kolees, the Gonds, and the Shanars. The distinction of castes did not exist among these people, and their religion seems to have consisted of the worship of a variety of spiritual deities. The Aryan Hindoos are supposed to have entered the country from the northwest, probably from regions between the Hindoo Koosh and the Caspian sea. They brought with them the Brahmanical religion, and formed the institution of caste by dividing themselves into the three higher castes of Brahmans, Kshatriyas, and Vaisyas, while the conquered people constituted the Sudras or servile caste. It is not known at what period this invasion took place, but it was undoubtedly prior to the 14th century B. C. The language of the conquerors was probably the

Sanskrit, in which their sacred books were written. The Vedas, supposed to have been compiled about the 14th century B. C., are esteemed the holiest. Two great dynasties, the kings of the race of the sun, who reigned in Ayodha, the modern Oude, and the race of the moon, who reigned in Pruyag, the modern Allahabad, figure in the legends of their early history, and their contests are recorded in the poem known as the *Mahabharata*. The most celebrated of these sovereigns was Rama or Ramchunder, who is supposed to have lived in the 12th or 13th century B. C. His deeds are the subject of the great epic poem the *Ramayana*. Subsequently long civil wars raged among the princes of the lunar race, which culminated in a great battle where the armies of 56 kings fought for 18 days. But the first event in the history of India of which we have an authentic account was the invasion by the Persians under King Darius, about 518-521 B. C. The Persian monarch conquered and annexed to his empire provinces on the Indus so rich and extensive that, according to the Grecian historians, their tribute furnished one third of the revenues of the Persian crown. In 327 B. C. Alexander the Great, having overthrown the Persian empire, invaded India, defeated Porus, one of the kings of the country now called the Punjab, and penetrated with his army as far as the Hyphasis (the Sutlej or its upper branch, the Beas). The historians of his expedition describe the manners, customs, and pursuits of the Hindoos in a way that shows they have changed but little since. In the division of the Macedonian empire after the death of Alexander, Seleucus, one of his generals, obtained the eastern part, and founded the Bactrian kingdom, which included the provinces on the Indus. He attempted conquests beyond that river, and was involved in war with Chandragupta, king of Maghada, whom the Greeks called Sandracottus. With this monarch Seleucus made a treaty by which the Greeks relinquished all claim to any possessions east of the Indus. The kingdom of Maghada comprised the greater part of northern and central India, and lasted till about 195 B. C. Its capital, Palibothra, was on the Ganges, but its precise site is unknown. After its downfall India was divided into a number of kingdoms, of whose history little is known, and that little has been gathered principally from inscriptions and coins. India's relations with the external world were again renewed about A. D. 715, when the Mohammedan governor of Bassorah sent by sea an army not exceeding 8,000 in number, commanded by Mohammed Kasim, to obtain restitution of an Arab vessel which had been taken near the mouths of the Indus not long previously. Kasim landed near the mouth of the Indus, and succeeded in conquering Sindh and the southern part of the Punjab, where the Mohammedans retained power for about forty years, when they were expelled by the Rajpoots. India re-

mained unmolested from that time till 977, when Subooktugeen, the Afghan sultan of Ghuzni, invaded a portion of the Punjab and took possession of Peshawur, but did not long retain his conquests. His son Mahmood made his first expedition into India in 1001, at the head of an army of 42,000 men, and conquered a portion of the north. In the course of his reign of 33 years, which ended in 1030, he made 10 expeditions into India for conquest and plunder. He left extensive possessions in western India to his successors, one of whom, Masaoud III., greatly extended the Mohammedan rule. He carried his conquests beyond the Ganges, and transferred his court from Ghuzni to Lahore. He was the first Mohammedan sovereign whose capital was within the limits of Hindostan. In the early part of the 12th century a civil war among the Mohammedan conquerors resulted in placing the house of Ghore on the throne of Lahore. One of the monarchs of this dynasty, Shahab ud-Din, better known as Mohammed Ghore, overthrew the kings of Delhi and Ajmeer, conquered Benares, Gwalior, Guzerat, and many other cities and provinces, and at the time of his death in 1205 was master of nearly all the country north of the Nerbudda, including Bengal, Sindh, and Guzerat. Under his successor, Kuttub ud-Din, a Turkish slave who had been educated by Shahab ud-Din, the Mohammedan dominions in India were separated from the Afghan empire and formed an independent kingdom, the capital of which was Delhi. Kuttub ud-Din was the founder of a dynasty known as the slave kings, ten in number, five of whom were violently deposed, and the last, Kei Kobad, was murdered in 1288. The most eminent of these sovereigns, Altmish, extended his dominions by conquests southward, and at the end of his reign all India N. of a line running from Surat to the mouth of the Ganges acknowledged the authority of the court of Delhi. Kei Kobad was succeeded by Jelal ud-Din, the founder of the dynasty known as the house of Khilji. During his reign, his nephew Alla ud-Din, an able and ambitious general, invaded and conquered a large part of the Deccan, and on his return from this expedition caused his uncle the emperor to be assassinated, and usurped the throne in 1296. He was one of the most eminent of the Mohammedan rulers of Hindostan, and in his reign of 20 years considerably enlarged the empire, maintained a brilliant court, patronized learning and the arts, and successfully repelled several great invasions of the Moguls or Tartars who had established themselves in the countries west of the Indus. He died in 1316, poisoned, it was generally thought, by his vizier. His three successors died by violence, and in 1321 the house of Khilji became extinct. Five emperors of that dynasty had reigned 33 years, and all had perished by poison or the sword. Toghluk Shah, the founder of the house of Toghluk, ascended

the vacant throne in 1321. He was one of the best of the Mohammedan sovereigns, but his reign lasted only four years, when he was killed by the fall of a pavilion which is supposed to have been intentionally caused by his son, who succeeded him under the name of Mohammed Togluk, and after a reign of about 27 years died in 1351, leaving, says a historian, "the reputation of one of the most accomplished princes and most furious tyrants that ever adorned or disgraced human nature." During this disorderly reign Bengal and several of the provinces of southern India became independent. Mohammed Togluk was succeeded after a short civil war by his cousin Feroze Togluk, the founder of Ferozabad, near Delhi, who reigned for 36 years, and was distinguished for humanity and for the vast number of public works which he constructed and endowed with revenues. In the reign of his grandson Mahmud Togluk, in 1398, India was invaded by the famous Tartar conqueror Tamerlane, who captured Delhi, plundered and slaughtered the inhabitants with frightful barbarity, and caused himself to be proclaimed emperor of India. At the end of 15 days, however, he abruptly quitted Delhi and returned to his own country, "marking his way with fire and sword, and leaving anarchy, famine, and pestilence behind him." The governors of the various provinces of the empire proclaimed their independence of Delhi, and assumed royal titles, so that only a small district remained subject to the authority of the imperial capital. Half a century of anarchy succeeded, during which there were five titular emperors in Delhi, who however had no real authority beyond the walls of the city. The Togluk dynasty ceased with the death of Mohammed Togluk in 1414. At length in 1450 Beylol Lodi, an Afghan military chief of talent and energy, made himself the actual sovereign, though nominally acting as vizier to one of the titular monarchs, whom he finally succeeded in 1478. Before his death in 1488, he succeeded in recovering many of the provinces which had formerly belonged to the empire. His son Sikunder still further enlarged his dominions in a reign of 29 years, during the latter part of which he made Agra his capital. Sikunder was succeeded by his son Ibrahim, in whose reign India was again invaded by the Moguls, led by a descendant of Tamerlane, the celebrated Baber, sultan of Cabool. Ibrahim was defeated and slain in a battle on the plains of Paniput in 1526, and Baber ascended the throne with little further opposition, the imperial cities of Delhi and Agra surrendering without resistance. In the course of his reign of five years, Baber, who had remained in India, made himself master of all the provinces which had belonged to his predecessor. He died in December, 1530, and was succeeded by his son Humayun, who allowed one of his brothers to hold Cabool and the rest of Af-

ghanistan as an independent kingdom, and contented himself with his Indian dominions. These he was deprived of at the end of nine years by Shere Khan, the governor of Bengal, a man of great military talents, who rebelled, defeated the emperor in several battles, and finally compelled him to fly for refuge to Persia. Shere Khan was then proclaimed emperor of Delhi, with the title of Shere Shah. He reigned with wisdom and success for about five years, when he was killed by the explosion of a magazine while directing the siege of a rebellious fortress. He was succeeded by his son Selim Shah Soor, and by his grandson Feroze Khan, the latter of whom after a few days' reign was murdered by his uncle Mubari, who usurped the throne and took the name of Mohammed Shah. In the mean time the exiled Humayun, by the aid of the king of Persia, had made himself master of Cabool, and now resolved on attempting the recovery of the throne of Delhi. This he successfully accomplished by the aid of his heroic son Akbar, and he reentered the city of Delhi, whence he had been driven 15 years before, in July, 1555. He did not survive his restoration to power more than a few months, being killed by an accidental fall from the terrace of his palace at Delhi. Akbar, who succeeded his father in 1556, reigned for 51 years. He is reputed the ablest, most liberal, and most powerful of the Mogul emperors of India. He restored the empire to its former bounds, reorganized the army and the finances in a statesmanlike manner, so that his revenues were largely increased while the burdens of the people were diminished, and treated all religions with respect and impartiality, freely admitting the Hindoos to a share in the administration of public affairs, from which they had hitherto been jealously excluded by their Mohammedan masters. Akbar was succeeded in 1605 by his son Selim, who took the title of Jehanghir, or "conqueror of the world." In the early part of his reign he was intemperate, capricious, and cruel; but his habits and conduct greatly improved after his marriage with the celebrated Nourmahal, "the light of the harem," one of the most extraordinary and accomplished women known to history, whose influence over the emperor was so great that it is said he took no step without consulting her, and that in every affair in which she took an interest her will was law. The last years of Jehanghir were embittered by the quarrels of his four sons, each of whom aimed at the succession, and who were at times in open rebellion against their father. He died in 1627, in the 22d year of his reign. He was succeeded by his favorite son Shah Jehan, in whose reign the Deccan was completely subdued and rendered tributary, and a long and eventually unsuccessful war was waged with the Persians and the Afghans. In 1657 he fell very ill, and being thought to be dying, his son Dara, the heir apparent, assumed the reins of government. The

other sons, Shuja, Murad, and Aurungzebe, who had each been appointed viceroys over important provinces, immediately revolted and prepared by force of arms to assert their pretensions to the succession. Shuja was defeated, but Aurungzebe by stratagem obtained possession of his father's person, and kept him in seclusion till he died, seven years afterward. Murad was also soon seized and imprisoned by Aurungzebe, who caused himself to be proclaimed emperor. Dara continued the contest for some time longer, but was finally captured and put to death. Shuja was driven with his family into exile, where they all perished. The reign of Aurungzebe, though it began with civil war and confusion, was more peaceful and orderly than that of any of his successors. The Mogul empire in India attained under him its greatest extent, including nearly all that is now known as Hindostan. He died in 1707 in the 89th year of his age, after a reign of 49 years. He was an ambitious and unscrupulous monarch, possessed of great talents, and eminent both as a statesman and a soldier. The Mohammedan historians regard him as the greatest of all the Mogul emperors. During his reign the foundation of the Mahratta empire was laid in the Deccan by an adventurer named Shevajee. (See MAHRATTAS.) Aurungzebe's eldest son, who succeeded him under the title of Bahadoor Shah, was involved at the beginning of his reign in civil war with two of his brothers, both of whom were killed in battle, and toward the end in a contest with the Sikhs, who were just beginning to acquire importance in the northwest of India. He died in 1712, and was succeeded by his eldest son Jehandar Shah, a weak and profligate ruler, who in the second year of his reign was defeated in battle and afterward strangled to death by his rebellious nephew Ferokshere. The reign of the latter lasted six years, and was remarkable only for conspiracies, insurrections, and general disorders in the capital and the provinces. He was at length put to death by his vizier and commander-in-chief, who in the course of the next eight months successively placed on the throne three infant descendants of Aurungzebe, the last of whom, Mohammed Shah, a youth of 17, soon became impatient of their control, of which he got rid by causing one to be assassinated and the other deprived of office. The emperor, however, was fickle and dissolute, and his dominions were invaded on one side by the Mahrattas, now rapidly becoming formidable, and on the other by the Persians, whose warlike monarch, Nadir Shah, passed the Indus with a great army, and overthrowing the imperial forces, took possession of Delhi in 1739. He remained several weeks in the Mogul capital, which he plundered of treasure amounting, according to the lowest estimate, to \$100,000,000, after massacring a great part of the inhabitants. He then returned to his own country, leaving Mohammed Shah in possession of his throne, and

depriving him only of the provinces west of the Indus. Mohammed Shah died in 1748, and was succeeded by his son Ahmed Shah, who after a reign of six years was deposed, and Alumghir raised to the throne, in the third year of whose reign Hindostan was invaded by the Afghans and again plundered. The Mahrattas, who were now at the height of their power, took advantage of the distress of the empire, and carried their arms into the northern provinces. The Afghans, under their sovereign Ahmed Shah Abdalli, met them at Paniput in January, 1761, and a great battle was fought, the forces on both sides amounting to 400,000 men. The Mahrattas were defeated with great slaughter, and it is said that 200,000 of them perished in the battle and the pursuit. The Afghans returned to their own country after this great victory, and left the government of Delhi to take care of itself. From this time, however, the Mogul empire was practically at an end. The English had now become the most important power in India. (See EAST INDIA COMPANIES.)—The first of the nations of modern Europe who obtained territorial possessions in Hindostan were the Portuguese, who early in the 16th century seized some ports on the western coast, and in the course of the century made themselves masters of Diu, Damaun, Bassein, Salsette, Bombay, Choul, Dabul, Goa, Mangalore, Cananore, Cranganore, Calicut, Cochin, and Quilon. Their capital was Goa, where they maintained a viceroy and an archbishop. During the union of Portugal with Spain, from 1580 to 1640, these distant possessions were neglected, and many of them were taken by the Dutch or regained by the native powers. Goa and a few small places of no political or commercial importance are all that now remain of the Portuguese empire in India. The English East India company, which was chartered at London in 1600, obtained permission of the Mogul emperor Jehanghir in 1613 to erect a factory at Surat. In 1628 they established a trading post at Armegoor, 70 m. north of Madras, and erected the first English fortifications in India there. They were allowed to build a factory at the mouth of the Hoogly, by a firman from the emperor Shah Jehan granted in 1634. In 1669 the island of Bombay was ceded to them by Charles II., who had acquired it as part of the dowry of his wife, the infanta of Portugal. It was in Bengal, however, that the company first began to acquire military and political power. They moved the factories on the Hoogly to Calcutta in 1698. They took into their pay bodies of native soldiers who were called *sepoys*, and were armed and trained in the European manner, and with the aid of these mercenaries they soon acquired a considerable degree of influence in the country. In 1744, France and England being at war in Europe, hostilities broke out between the English and French in India. The capital of the French possessions was Pondicherry, which

had dependent on it three factories, one at Mahé on the Malabar coast, one at Karikal on the Coromandel coast, and one at Chandernagore in Bengal. The contest in India, though conducted with great energy and ability by Dupleix and Bussy on the part of the French, and by Laurence and Clive on the part of the English, led at that time to no important results, but was renewed in 1756. In that year Surajah Dowlah became subahdar or viceroy of Bengal, and, having always disliked the English, soon found a pretext for making war upon them. Commencing hostilities suddenly, while the English were yet unprepared, he captured Calcutta; and the English portion of the garrison of Fort William, amounting to 146 persons, of whom Mr. Holwell was the chief, were shut up in the "Black Hole," where all but 23 of them perished in a single night by suffocation. (See BLACK HOLE.) Clive soon retook Calcutta with a force from Madras, captured Chandernagore and its French garrison, and after various other successes defeated the subahdar's army in the decisive battle of Plassey, June 23, 1757. In the Carnatic the French were completely defeated by the English on Jan. 22, 1760, in the battle of Wandiwash. After Plassey Surajah Dowlah was dethroned and put to death, and his vizier Meer Jaffier raised to the vacant throne. The new sovereign granted to the English, as the price of their support, an immense sum of money, a large accession of territory, and permission to keep such of the French posts and factories as they could conquer. These transactions involved the English in a war with the emperor of Delhi, and with his vassal the nawaub of Oude. Both the emperor and the nawaub succumbed after a brief contest, and by the treaty of peace the emperor ceded to the British the provinces of Bengal, Behar, and Orissa, together with the maritime districts known as the Northern Circars. The real sovereign of the Northern Circars was a potentate called the nizam of the Deccan, who gave to the emperor of Delhi only a nominal allegiance. At first the nizam declined to acquiesce in the cession, but subsequently he consented to it on condition that the English should aid him with troops against Hyder Ali, the warlike and politic sovereign of Mysore. In the war that ensued the English, notwithstanding some successes, were so hard pressed that they sought to stop the progress of Hyder by negotiation, and at last concluded, in April, 1769, a treaty with him which resulted in a mutual restitution of conquests. In 1772 Warren Hastings assumed the administration of the East India company's affairs in Bengal, and in 1774 received the title of governor general, being the first officer so designated. In return for the cession of Benares, he furnished troops to aid the nawaub of Oude in the subjugation of Rohilcund. The first war with the Mahrattas soon broke out, and considerable conquests were made, which were nearly all given up by a

peace hastily concluded with them in consequence of the breaking out in 1780 of a war with Hyder Ali, who died Dec. 7, 1782, while the war yet raged, leaving his kingdom to his son Tippoo Sahib, who in 1784 agreed to a treaty of peace. In 1781 Hastings aided the nawaub vizier of Oude, then deeply in debt to the Bengal government, in exacting from the begums or princesses of that state at least £760,000 of the apanages which had been allotted to them for their maintenance on the nawaub vizier's accession in 1756. Having resigned, he was succeeded as governor general by Sir J. McPherson in 1785; but before he embarked for England he caused the nawaub to restore most of the amount extorted from the begums. In December, 1789, Tippoo again became involved in war with the English by an attack upon the kingdom of Travancore, which was under their protection. Lord Cornwallis, conspicuous in the history of the American revolution, became governor general of India in 1786, and conducted the contest with such energy, that in 1792 Tippoo was compelled to agree to a treaty by which he ceded to the English about half of his dominions, and paid them £3,300,000 in money. Sir John Shore, afterward Lord Teignmouth, became governor general in 1793, and in 1798 was succeeded by the earl of Mornington. In the latter year Tippoo was incited by emissaries of the French republic, then engaged in hostilities with Great Britain, again to make war on the British, which resulted in the storming of his capital, Seringapatam, and his own death in the conflict, May 3, 1799. His dominions were divided between the English and their ally the nizam, and the earl of Mornington was created Marquis Wellesley in recognition of his successful administration. In 1803 a war broke out between the English and the Mahrattas, which proved to be the most serious ever waged by them in India. It was conducted by Gen. Lake and by Sir Arthur Wellesley, afterward the duke of Wellington, and by the brilliant success of these great commanders was terminated in December with the destruction of the Mahratta power and a vast acquisition of territory by the East India company. In consequence of border forays and outrages, war was declared against the Gorka state of Nepaul in 1814, which resulted in a further augmentation of British territory. The same result followed the war of 1817-'18 with Holkar, the peishwa, and other powerful chiefs, in which the Mahratta power was finally subdued. Much trouble at this period was experienced in central and southern India from a formidable force of mounted marauders called Pindarries, who acted as allies of the hostile Mahratta chiefs, and were defeated with them. A war with the Burmese in 1824-'25 led to large accessions of territory on the eastern frontier, comprising Assam, Aracan, and Tenasserim. The Afghan war, which began in 1839, after great disasters to the English arms, amply redeemed by subsequent successes, terminated in

the withdrawal of the British from Afghanistan. The annexation of Sinde in 1843 was followed by the wars with the Sikhs, who had been organized into a powerful military state by their great sovereign Runjeet Singh. Hostilities began in 1845, six years after his death, and finally resulted in the annexation of the Punjab by the English in 1849. A second war with the Burmese terminated after a short contest, in December, 1852, with the acquisition of the extensive province of Pegu. In 1856 the kingdom of Oude, which had for some years been in a state of confusion, was annexed to the British dominions on account of its extreme and scandalous misgovernment. From 1805 to 1855 the governors general of India, with the respective dates of their accession, were as follows: Marquis Cornwallis, 1805; Sir G. Barlow, 1805; earl of Minto, 1807; Earl Moira (marquis of Hastings), 1813; Earl Amherst, 1823; Lord W. Bentinck, 1828; Lord Auckland, 1835; Lord Ellenborough, 1841; Sir H. (Lord) Hardinge, 1844; Earl (marquis of) Dalhousie, 1848; and Lord Canning, 1855. The next important event was one which attracted the attention of mankind in all quarters of the globe, and forms unquestionably the most impressive incident in the annals of British India. This was the great sepoy revolt. The year 1857-8 was the Hindoo Sumbut 1914, in which fell the centenary of the battle of Plassey; and Hindoo astrologers had long predicted that in this year the power of the East India company would terminate for ever. In the early part of 1857 it became apparent that a mutinous spirit had crept into the Bengal army. The military authorities had resolved to arm the sepoys with Enfield rifles, and a new kind of cartridge, greased in order to adapt it to the rifle bore, was introduced into many of the schools of musketry instruction. A report spread among the native troops that, as the cartridges in loading had to be torn with the teeth, the government was about to compel them to bite the fat of pigs and of cows, the former of which would be defilement to a Mussulman, and the latter would be sacrilege in the eyes of a Hindoo. The wildest excitement prevailed for a time, but the substitution of the old for the new cartridges temporarily prevented an outbreak. Meanwhile, though the greased cartridges had not been used elsewhere, the cry of danger to caste and creed was raised in many other stations. Disturbances occurred on Feb. 19 at Burrampoor; March 29 at Barrackpoor, where the first blood of the revolt was shed, the leader in the revolt being a private sepoy in the 34th native regiment, named Mungul Pandey; and April 24 at Meerut. On May 10 a formidable rising took place at the latter station. The Europeans were massacred, and the mutineers marched to Delhi, where the garrison fraternized with them and a second butchery was committed. The rebels proclaimed the restoration of the Mogul dynasty, and thenceforth acted in the name of

the king of Delhi, though without much deference to his orders. The king thenceforward took an active part in the revolt, and Delhi became a rallying point for the mutineers from other quarters. In the Northwest Provinces risings took place almost simultaneously at Allyghur, Boolundshahur, Minporee, Shahjehanpore, Etawah, and Bareilly. The sacred city of Benares on the Ganges was in revolt on June 4, and on the next day at the military station of Cawnpore several thousand sepoys revolted and placed themselves under the command of the Nana Sahib, rajah of Bithoor, and on June 27 the terrible massacre at Cawnpore took place. (See BITHOOR, and CAWNPORE.) About the same time the ferocious rane (princess) of Jhansi in Bundelcund took the field at the head of two regiments which mutinied at Jhansi June 4. In the course of June and July Jounpoor, Allahabad, Futtehpoor, Nowgong, Bandah, Mozuffernugger, Agra, Jhylum, Saugor, Sealkote, Segowlie, Dinapoor, and Rangurh became the theatres of commotion, and in many instances of massacre. In the recently annexed kingdom of Oude, from which a large proportion of the sepoys in the Bengal army had been recruited, the rising, which elsewhere was purely military, partook of the character of a popular insurrection, the people generally favoring and assisting the rebels. The native troops at Lucknow, the capital, mutinied May 30 and 31, and nearly every sepoy regiment in Oude soon followed their example. The troops proclaimed allegiance to the ex-king of Oude, and gradually closed around Lucknow, where they began to besiege the Europeans about July 1. The Punjab was saved by the administrative capacity of Sir John Lawrence; a few risings took place, but the rebels were nearly all cut to pieces, and the suspected regiments seasonably disarmed. The presidency of Bombay was but little disturbed, and that of Madras was tranquil with scarcely an exception. Lower Bengal was also comparatively quiet, the insurrection assuming the most serious aspect in Behar, Rohilcund, Bundelcund, the Doab, Malwa, Rajpootana, and Oude. The two principal Mahratta chiefs, Sindia at Gwalior and Holkar at Indore, remained faithful, but the revolt of their respective contingents was one of the most serious disasters to the British during the war. In May, 1857, the Bengal army comprised 22,698 Europeans (including the officers of native regiments) and 118,663 natives. The native force was disposed in 167 regiments and irregular corps, of which by the end of December 76 had mutinied and 27 had been disarmed or disbanded. As soon as the revolt broke out the British made strong efforts to suppress it; but the resources of treachery, the paucity of European troops, and the absence of means of transport gave the rebels an immense advantage. In a number of instances, mutineers detected or captured by the British garrisons were executed by being blown away from the mouths of cannon. Gen. the Hon. George

Anson, the commander-in-chief, died May 27, 1857, soon after taking the field, and was succeeded provisionally by Sir Henry Barnard. The first movements were against Delhi, which was stormed Sept. 14, after a siege of three months, which was conducted successively by Gens. Barnard, Reed, and Wilson. The troops entered the city, and occupied a part of it on the first day, but did not subdue the last stronghold until Sept. 20. The king was captured and ultimately sentenced to perpetual exile, but most of the rebels escaped. Two sons and a grandson of the king were made prisoners a short distance outside the city by Capt. Hodson, who shot them all with his own hand. Meanwhile Gen. Havelock, having collected a small force at Allahabad, moved toward Cawnpore, where more than 200 women and children, who had escaped the previous massacre, were cruelly put to death, July 16, shortly before he entered the city. He followed the Nana Sahib to Bithoor, defeated him, and, having been joined by Gens. Outram and Neill, crossed into Oude to relieve Lucknow, where Sir Henry Lawrence, the chief commissioner of Oude, had died of a wound on July 4, and the garrison under Col. Inglis was now reduced to extremities. He fought his way into the city Sept. 25, Gen. Neill being killed in the action; but beyond an accession of numbers his arrival did not benefit the besieged. Sir James Outram assumed command, and their condition remained unchanged until Sir Colin Campbell, who had arrived in India Aug. 14, with the rank of commander-in-chief, relieved them, Nov. 14-19, and enabled them to withdraw to Cawnpore. Gen. Havelock died Nov. 24. On Dec. 6 Sir Colin Campbell defeated the Nana Sahib with 25,000 rebels at Cawnpore, and, making that city a centre of operations, proceeded to attack the rebels of the Northwest Provinces in several quarters at once, with a view of driving them into Oude, where a combined movement could subsequently crush them all together. The brigades of Lugard, Hope Grant, Sir Hugh Rose, Roberts, Steuart, Showers, Stuart, and others, did good service in the disturbed districts, and Gen. Outram continued to hold the Alumbagh fort near Lucknow, which had not been evacuated with the city. By Jan. 1, 1858, 23 European regiments had arrived at Calcutta, besides those which landed at Madras and Bombay; the Nepaulese chieftain Jung Bahadour furnished a valuable subsidiary force of Gorkhas, the Sikhs were enlisted, and Lawrence was able to supply troops from the Punjab. Lucknow was gradually retaken by Campbell and Jung Bahadour (March 2-21), and the army which had been concentrated for this purpose was then broken up into detachments for service in Rohilund and other districts. Sir Hugh Rose, with a detachment from the Bombay army, stormed Jhansi, April 2, and pursued the ranee or chieftainess and the noted rebel leader Tantia Topee to Cal-

pee, where he defeated them, and thence to Gwalior, which had now become the stronghold of the mutiny, as Delhi and Lucknow had been before it. Gwalior was taken, June 20, after the ranee had been killed. This was the last great battle of the campaign, although the rebels, headed by the Nana Sahib, the begum of Oude, Tantia Topee, Maun Singh, and Feroze Shah, a prince of the house of Delhi, maintained an obstinate resistance throughout 1858-'9. Though repeatedly beaten in the field, they always escaped destruction to reappear in another quarter. Oude was gradually pacified, however, in the autumn, and about Feb. 1, 1859, Sir Colin Campbell, whose services had been recognized by the bestowal upon him of a peerage, under the title of Lord Clyde, declared the campaign there at an end. The whole population was disarmed in the course of the spring and summer, 1,327 forts being destroyed and 1,367,406 arms of all kinds surrendered. Tantia Topee was captured, tried by court martial, and hanged. Of the number of Europeans massacred or killed in battle during this mutiny no accurate estimate can be formed. Hundreds of English women and children were put to death after horrible outrages, many stories of which were perhaps fictions or exaggerations, though unhappily the substantial truth of the accounts of these atrocities cannot be doubted. The rigor evinced by the English in punishing the rebels was in many cases almost equally shocking. One very important result of the mutiny was the transfer of the government of India from the East India company to the direct authority of the British crown. This was accomplished by an act of parliament, providing substantially for the system of administration which now exists. Lord Canning, who had continued in office during the whole mutiny, resigned in 1862, and Lord Elgin succeeded him; but the new viceroy died in the following year, and Sir John (subsequently Lord) Lawrence was appointed. A badly conducted war with Bootan, growing out of territorial disputes, was the most important event of 1864 and 1865; its result was not very satisfactory to the British. Owing to the deficient rainfall of the previous year, a terrible famine broke out in Orissa in 1866, and is believed to have caused the death of 2,000,000 persons. Sir John Lawrence was succeeded in 1868 by the earl of Mayo, who was assassinated by a prisoner at Port Blair, in the Andaman islands, while on a visit to the penal colony there, Feb. 8, 1872. No political significance appeared to attach to the crime. His successor, Lord Northbrook, is the present governor general (1874). The resources of his administration have been severely taxed to avert the famine with which Bengal was threatened in consequence of the lack of rain in 1873.—The annual "Statement exhibiting the Moral and Material Progress and Condition of India," which has been furnished to parliament by the authority of the secretary of state for In-

dia since 1864-5, and the various official publications of the Indian government itself, are the principal sources of recent statistics concerning the country. A complete general account of a single province, such as the statistical survey is designed to obtain of every part of India, is contained in "Orissa," by Dr. W. W. Hunter (2 vols. 8vo, London, 1872). The following are noteworthy among the numerous historical and political works relating to India: "History of British India," by James Mill, with continuation by Wilson (9 vols. 8vo, London, 1858); "History of India," by Mountstuart Elphinstone (5th ed., 1866); "History of the British Empire in India," by Edward Thornton (6 vols., 1842-5); Wilkes's "History of Mysore" (3 vols. 4to, 1810-17); "History of the Mahrattas," by James Grant Duff (3 vols. 8vo, 1826); "Memoir of Central India," by Sir John Malcolm (2 vols., 1832); "Life of Lord Clive," by the same (3 vols., 1836); "History of the British Empire in India, from the Appointment of Lord Hardinge to the Death of Lord Canning," by Lionel J. Trotter (2 vols., 1866); "The Administration of the East India Company," by J. W. Kaye (1853); "The Sepoy War in India," by the same (2 vols., 1869-70); "Lives of Indian Officers," by the same (2 vols., 1867); "Indian Polity," by Major George Chesney (1868); "Annals of Rural Bengal," by W. W. Hunter (5th ed., 1872); "Life of Sir Henry Lawrence," by Sir Herbert Edwardes and Herman Merivale (2 vols., 1872); "The Administration of India from 1859 to 1868," by J. T. Prichard (2 vols., 1869); and "History of the Administration of Lord Ellenborough," by Lord Colchester (1874). A concise account of Indian history is contained in "A Student's Manual of the History of India," by Meadows Taylor (12mo, London, 1870). In Alexander Cunningham's work on the ancient geography of India (vol. i., London, 1870) is an elaborate description of the earlier divisions of the country. For an account of the botany of India, see the "First Book of Indian Botany," by Prof. Daniel Oliver (16mo, London, 1869), where it is stated that there is no good work on the general botany of India. A list of the mammalia of India S. of the Himalaya can be found in Blyth's "Catalogue of Mammals in the Museum of the Asiatic Society" (1863), extracted into Andrew Murray's "Geographical Distribution of Mammals" (4to, London, 1866). As to Indian natural history, see also "Wanderings of a Naturalist in India," by A. Leith Adams (Edinburgh, 1867), and "The Highlands of Central India," by Capt. J. Forsyth (London, 1871).

INDIA, Races and Languages of. The population of India, without special reference to the latest intruders who have preserved their original characteristics and imposed their own institutions, may be divided into Aryans and Dravidians. The testimony of history and the internal evidence of Sanskrit literature seem

to establish that the Aryans invaded the land earlier than 1500 B. C. from a N. W. direction, being the kin of the Iranian or Persian races. They first became possessed of the Punjab, and through long ages of warfare advanced ultimately to the lower course of the Ganges. There is no doubt that the original population was in a great measure Dravidian, though, as Huxley says, whether it was already mixed with a Mongoloid element from the north-east or not does not appear. Thus, ethnologically considered, the Aryan races of India form the most eastern branch of the Aryan or Indo-European family of mankind, and the Dravidians or aboriginal races are a group either entirely distinct, or more or less remotely related to the Mongolians or Turanians. Comparing the former with the latter, it is found that constant commingling has rendered them almost undistinguishable; and judging from physical characteristics alone, disregarding the totally distinct forms of speech, both divisions are to all appearance nearly the same. They are rather small, lithe, delicate, and mostly of a yellowish complexion. The aristocracy among them, however, are almost white, and the Deccanese nearly brown. The hair is long, straight, and black; the eyes are black and shaded by long eyelashes; the ears are well formed; the mouth is not very large; the lips are thin; and the hands and feet are small. The various classes of the Aryan population are enumerated as follows by Sherring and Campbell: *a*, Brahmans, originally priests, now of diverse avocations; *b*, Jats, agriculturists; *c*, Rajpoots, originally the conquerors of western India, now agriculturists; *d*, Koorbees or Koonbees, likewise agriculturists; *e*, Goojars, mostly shepherds; *f*, Aheers, shepherds; *g*, Gwalas, shepherds; *h*, Khatrees, tradesmen; *i*, Banyans or Baniyas, merchants; *j*, Kayasth, secular scribes; *k*, Parbhu, clerks; *l*, artisans; *n*, helots, in part rendering menial services, and in part leading a nomadic life.—The Cashmerians are probably the best representatives of the early Hindoos; the bulk of them are now Mohammedans, but all who have adhered to their own faith are Brahmans. In the western hill country are the Mahratta Brahmans, who are mentally and physically very similar to the Cashmerians. Further south, along the slopes of the Ghauts, are Brahmans who follow agricultural pursuits. They are not as numerous on the upper Ganges as in the lower Doab; they are numerically strong in their famous seat Kashee or Benares. Beyond Benares is a race of bastard Brahmans called Bamums or Bhalbuns. Brahmans are the dominant people in Behar and the adjacent countries, and also in the furthest east of Bengal. The Cingalese or inhabitants of Ceylon are in many respects like the Bengalese. They are supposed to be a mixed race, descendants of the aboriginal inhabitants and of an ancient Brahmanical emigration from Bengal. The Khatrees of the Punjab are supposed to be descendants of the ancient Kshatriyas; they are

few in number, but they are intellectually and physically fine men; and it has been said, "Name a distinguished Hindoo, and there is a very great probability that he will turn out to be a Khatree." They are now principally engaged in mercantile pursuits in the Punjab. Although the Rajpoots are now quite Hindooized, it is not generally supposed that they are of a pure Hindoo origin; they have no tribal or caste name, Rajpoots being a title, signifying "sons of rajahs," and their other appellation of Thakoors signifies "chiefs." They were probably in former times in possession of the Punjab, but they have been submerged there by the advancing Jats. A Rajpoot tribe called Dogras still possess the lower hills to the north, and their chief is now lord of Cashmere. The Gangetic basin is the great Rajpoot country of history, and they are still very numerous there. They have never actually conquered the aboriginal people, but Rajpoot families have by mere force of character established themselves as chiefs over many of the hill tribes, and, adopting a feudal system similar to that which once prevailed in Europe, they now rule all the races of Rajpootana. The Jats probably arrived in the country later than the Rajpoots; they seem to have entered by the Bolan pass in the north, where some of their people settled among the hills, and have thence gradually overspread the whole country. They are extremely robust and warlike, excellent subjects, admirable agriculturists, and good revenue payers. Physically there is no finer race in India; they are tall and strong, with fine features, fine teeth, and very fine beards. In their institutions they are democratic, and every village is a complete little republic. Most of the remaining modern divisions may be described as mixed, though Aryan features and institutions prevail among them. The Koorbees or Koonbees are a great agricultural race, occupying large parts of Guzerat, and scattered to some extent over the whole Mahratta country. It is difficult to understand how the quiet and unwarlike Mahratta cultivators could ever have been the warlike people so famous in recent history. It seems, however, that the hardy military Mahrattas came exclusively from the S. W. parts of the country, where they had largely mixed with the aboriginal tribes of the Western Ghauts. The ruling Mahrattas of Nagpore come from the Sattara country. The remainder of the Mahratta armies were made up of adventurers of every caste and creed. In this they differed from the Sikhs, whose forces were mainly their own free people, the Jats. Other Aryan races are probably represented by the more pastoral or cowherd tribes; they are the Goojars of the north, the Aheers of Hindostan proper, the Gwalas of Bengal, and the Goordees of central India. The last three are of a type less alloyed than that of most tribes. Local tradition and general consent attribute to them the old ruins and remains of former greatness so common in this part of the

country, and the curious cairns and stone circles are also supposed to have been erected by them. In every part of India, and forming an essential part in the social structure, are found helot races among the free; they are not slaves, but politically and socially they are the lowest class of subjects. In the Punjab they are the Chooras; in Hindostan, the Choomars; in the Mahratta country, the Mhars. The Chooras are of a fair Aryan type; the Choomars generally have round faces, small features, and dark complexions, and possess only a very slight infusion of aboriginal blood; in the Mhars, and in some of the lower castes of Bengal, the aboriginal features are more decidedly represented. A very remarkable race are the traders known as Banyans, Banees, Wanees, Baniyas, Bunneahs, or Bunijugas; they form an important class of the population of the western countries of India. The North-western Provinces are in respect of commerce entirely in their hands; Guzerat, Malwa, and the Bombay district are full of them, and they are numerous also in the Canarese country. They are famous for their trading acuteness. It is supposed that the Jains also belong to the Banees caste; they are a mercantile body, and conduct almost exclusively the entire banking business of India.—The name of the Dravidians or Dravidas, who are considered to be the aborigines of India, is derived from Dravida, the Sanskrit name of the southern portion of the peninsula. The native Sanskrit lexicons define a Dravida as "a man of an outcast tribe, descended from a degraded Kshatriya." The term Dravidian, therefore, seems to have been applied by the Aryan invaders to the inhabitants of southern India at a very early period, probably about the 6th century B. C. They may also be divided into Kols or Mundas, inhabiting the northern districts, Dravidians proper or those of the south, and Cingalees or inhabitants of Ceylon. The Brahooees of Beloochistan are a Dravidian race. Hodgson designates the Dravidians proper as Tamulians. Campbell has given to the northern Dravidians the name of Kolarians, from the name Kolar by which India was known in ancient times. The term Kol is specially applied to the non-Aryan inhabitants of the hill country of Chota Nagpore, Mirzapoor, and Rewah. Mundas is used instead of Kol by other authorities, as the Mundas were the prior occupants of this region. To the Kols or Mundas belong the Santals, Singhbhoom Kols, Ramoosees, Bheels or Bhillas, Kolees, and other tribes. To the Dravidians proper belong the Tamils, Telugus or Telingas, Canarese, Malayalas, Gonds, Kolhs of the Rajmahal hills, and many others. The Santal or Sonthal tribe appears to be very widely spread; it is found in Chota Nagpore and in the skirts and valleys of the Rajmahal hills; according to Capt. Sherwell, its range is from Cuttack through Chota Nagpore to Rewah. The Kols in the Singhbhoom district are termed Lurka Kols. The tradition among the people is that they came

originally from Chota Nagpore, and are descendants of the old Mundas of that district; they have also the same cast of countenance as the Mundas, though perhaps with a wilder and fiercer expression. The Ramoosee tribes are spread over the central and western parts of the peninsula, and are partly predatory. The Bheels, as a distinct tribe, are found chiefly on the hills surrounding the fortress of Asirgurh in the Central Provinces. The Bheels of Berar occupy the eastern slopes of the Gawilgur range to its western extremity and reaching far into Candeish. The same people are also in possession of the eastern part of the Western Ghats, and all the branches that run out from it toward the east as far south as Poonah; they have even spread over the plains to the east, especially north of the Godavery, and the neighborhood of the Wurda. Latham says that the Bheels seem to have been the aborigines of the hills near Mount Aboo, but at some time or other they mixed with marauding Rajpoots from the plains, and with the workmen who were so long engaged in building the Dilwarra temples. The Kolees are a numerous race on the western side of India, being the laborers and low cultivators in Guzerat; they are also in large numbers in the western part of the Nizam's Dominions. Kolee is also the name given to the lower class of cultivators in the Simla hills. The same race is scattered over a great portion of the Bombay presidency, from the Thur and the neighborhood of Sinde southward to Goa and eastward along the banks of the Beema, the Kistnah, and Tumbuddra, into the centre of the peninsula as far as Kurnool, where they act as ferrymen. The Kolees and Bheels seem to have a similar if not a common origin. In some portions of India they are mixed, and Kolees frequently marry Bheel wives. The most important race of the Dravidians proper are the Tamils or Tamuls, and the name of Tamulian is sometimes used for the whole Dravidian group. Their number is estimated at 10,000,000; they inhabit principally the extreme southeast of the peninsula and N. and E. Ceylon. They are dark brown, very small, lithe, active, social, and more given to seafaring and emigration than any other Indian race. They wander along the coast and to remote islands for employment, and have given the name cooly (Tamil, *kuli*, hire) to the whole class of Indian laborers. The Telugu or Telinga people are estimated at about 14,000,000; they inhabit the eastern borders of the peninsula. They are a taller and fairer race than the Tamil, and equally energetic, though less restless. They are the Andhra of Sanskrit writers, a name mentioned by ancient Greek geographers as that of a nation dwelling on or near the Ganges. They are good farmers, and many of them were formerly seafaring men, undertaking long voyages. They held at one time large islands in the eastern archipelago, where the people of India are still called Kling, from the former Kalinga dynasty. The

people called Canarese are about 5,000,000 in number, and are found chiefly in the centre of the peninsula. They are a tall and singularly graceful race. Their avocations are mostly those of civil life, cultivators and shopkeepers. People speaking Canarese are spread over the plateau of Mysore and the western districts of the Nizam's Dominions, extending as far north as the neighborhood of Beder. The Kotar, who speak a dialect of Canarese have seven villages in the vicinity of Kotagherry, and are supposed to number a little more than 1,000. Dead cattle and carrion of every kind find acceptance among them as food. They are, however, the most industrious of the hill tribes, giving much attention to agriculture, and finding employment as carpenters, smiths, basket makers, and menders of ploughs. They are well built, of a tolerable height, rather good-featured, copper-colored, and may be considered among the fairest tribes of this portion of the country. In the low country and along the Western Ghats, from Cape Comorin to the Chandagiri river, live a people speaking the Malayalam or Malealam language. These inhabitants of Malabar, who probably number about 2,500,000, have from their situation in the extreme southwest been little exposed to external influences. They are of an exclusive disposition, avoid contact with foreigners, and live isolated with their families in their high-walled *parambu*, even where the enterprising Tamil people have opened lines of communication. The race speaking the Tulu or Tuluva tongue live in a small tract of country in the vicinity of Mangalore, and probably number no more than 150,000. Malayalam and Tulu are considered to be in a gradual course of extinction. The Toda, properly Tuda or Tudavera, are a primitive tribe hardly 500 in number, occupying the Neilgherry mountains in the southern part of the Indian peninsula, and commonly believed to be the aboriginal inhabitants of these hills. Logan styles their physical appearance Indo-Semitic. The Kotar tribe ranks next to the Toda in priority of occupation of the hills, but the Badakar, also called Budugur, Budaga, and Vadakar, are the most numerous. The other tribes on these hills live in isolated communities, but the Badakar dwell in villages with streets running in parallel lines, and in thatched houses built of stone and mud, and divided into separate compartments, but strangely enough with no other opening than a doorway about 40 inches high and 25 broad. The Badakar is smaller in stature and lighter in complexion than the Toda. The district of Coorg is inhabited by about 40,000 natives called Koodaga. They are a tall, muscular, somewhat civilized and intelligent race. The Coorgs divide themselves into Coorgs and Amma Coorgs. They have a fair complexion, and wear whiskers and mustaches, but never a full beard. A very important aboriginal tribe is that of the Gonds. (See GONDS.) Mr. J.

Murdock estimates the aboriginal tribes of the northeast at about 300,000, those of central India at about 7,000,000, and the hill tribes of southern India at about 700,000.—Altogether the population of India comprises more than 50 different races, and is characterized by the greatest diversity of appearance, manners, language, and religion. In 1871 the British-born inhabitants, exclusive of soldiers, numbered 64,061. The main division of the native people as to religion is into Hindoos, who form the bulk of the population, and Mohammedans, of whom the estimated number in the entire country is 40,000,000. There are also several millions of Buddhists and about 200,000 Parsees. The Mohammedans are chiefly found in the plain of the Ganges, where for several centuries they held dominion as conquerors and masters of the country, until their power was overthrown by the English. They entered Hindostan in the beginning of the 11th century from Afghanistan, and their numbers were swelled by successive invasions for several centuries afterward. In character the Mohammedans are distinguished from the Hindoos, and especially from the Hindoos of Bengal, by greater energy and frankness, by pride and arrogance, and by their luxurious and dissolute habits. They are of a hasty, revengeful, and fanatical disposition, and do not submit with patience to the domination of their English conquerors. The Parsees are but little darker in complexion than the inhabitants of the south of Europe. They are descendants of the ancient fire worshippers, who fled from Persia several centuries ago in consequence of persecution by the Mohammedans, and are now numerous in Bombay and in some other cities in western India. They form an intelligent, enterprising, and prosperous portion of the native population. The Sikhs, a peculiar religious sect, are numerous in the northwest, and have acted an important part in the history of India. After an existence of 400 years, their numbers are only estimated at from half a million to a million. (See SIKHS.) The estimated number of Jews in India is 10,000; some of those who inhabit Malabar have perfectly black complexions. There is also a large body of native Christians in Malabar, who are believed to be descended from converts made at a very early period of our era. (See CHRISTIANS OF ST. THOMAS.) The native Protestant converts to Christianity in India probably exceed 250,000; and according to a statement prepared for the council of the Vatican in 1870, there are 1,076,102 Roman Catholics in India. The number of Christians in the provinces directly subject to British control is 197,880, according to the latest enumerations, which were made from 1867 to 1872 inclusive. For special accounts of some other classes of the people of India, see FAKIRS, PARIKHS, and THUGS. For an account of the division of the people into castes, see INDIA, RELIGIONS AND RELIGIOUS LITERATURE OF.—

LANGUAGES. The early Aryan invaders spoke a language which has been preserved in the Vedas, and which bears the name of Sanskrit (*saṁskṛta*, perfect), as it is considered to be the most cultivated and perfected. (See SAN-SKRIT.) When this language came to be specially used for literary purposes, colloquial speech soon departed from the standard which was set up for it. It is probable that even in the most remote historical age of the Aryan people different tribes were characterized by dialectical differences of speech. These uncultivated forms of the language received from the Hindoos the name of Prākṛit (*prakṛti*, nature), in distinction from Sanskrit. Prākṛit is therefore the general term for the various dialects which arose during the centuries immediately preceding our era. The rock inscriptions of King Asoka, which record names of Greek princes of about 200 B. C., and the legends on the bilingual coins of Bactria, are written in this language. It also plays an important part in ancient Hindoo dramas; for while the heroes speak Sanskrit, the women and attendants use various forms of the popular dialects, which again appear more or less regular, or like the literary language, according to the rank of the speaker. In course of time it became customary to put the same dialectical variation always into the mouths of certain classes of the population. Whether these dialects were used on the stage in imitation of the real speech of the people, and whether they were strongly intermixed with Sanskrit in order to make them more easily understood by the public, cannot be decided. The rise of Buddhism, which was mainly a religion of the people, rendered one of the popular dialects spoken by Buddha himself of special importance. This Prākṛit language is called Pāli, but the precise meaning of this word is not known. Pāli has long ceased to be spoken, but is still used in the Buddhist scriptures of Ceylon, Burmah, and Siam. "Prākṛit," says E. B. Cowell, "almost always uses the Sanskrit roots; its influence being chiefly restricted to alterations and elisions of certain letters in the original word. It everywhere substitutes a slurred and indistinct pronunciation for the clear and definite utterance of the older tongue." All the modern Sanskrit idioms of India are related to the Prākṛit dialects, and they differ from the ancient mother tongue rather in grammatical forms than in roots and themes. Fr. Müller classifies them into six groups. The eastern group comprises Bangālī or Bengalee, the language of the province of Bengal, Assamī or Assamese, and Oriyā. To the northern group belong the Nipālī or Nepalese, the language of Nepal, Kaçmīrī or Cashmerian, and Panjābī or Punjaabee, the language of the Punjab. The western group embraces the Sindhī, which is spoken in the valley of the lower Indus, the Multanī, and several minor idioms. The central group includes the Hindī, the language of the native Hindoo population of the

central portion of northern India; Urdu, also called Hindústāni, an offshoot of Hindi, the language of the Mohammedan population of the whole of India, and spoken by all the cultivated classes of the peninsula; and Dakhani or Deccanese, also a Hindi dialect. The south-western group comprises Guzarāti or Gujarati, the language of Guzerat and the dialects related to it. The last and southern group is formed by the Marāthī.—All these languages with one exception make use of graphic systems differing from each other, but in common derived from the old Indic Dēvanāgarī alphabet, which in its turn is an adaptation of the Semitic characters, and especially of the Himyaritic. Urdu or Hindústāni, and often also Sindhī, is written with the Arabic-Persian Taliq characters. All the languages possess the same five classes of consonants, corresponding with those of Sanskrit: gutturals, palatals, cerebrals, dentals, and labials. They have also in common the peculiar semi-vowels *v*, *y*, *r*, and *l*, as well as the aspirate *h*. The vowels are *a*, *i*, and *u*, with the extended *ā*, *ī*, and *ū*; the closed diphthongs are *ē* and *ō*, and the open diphthongs *ai* and *au*. Several of these languages also reckon *r* and *l* as vowels. The following are the four principal graphic systems, arranged according to the sounds; the method of transcription employed is that given in Lepsius's "Standard Alphabet," for which see WRITING:

—Bangālī or Bengalee distinguishes the masculine, feminine, and neuter genders, and the singular and plural number. Nouns possess nominative, genitive, dative, accusative, vocative, ablative, instrumental, and locative cases. The mode of declension is as follows: singular—nom. *balād* (বালদ), an ox, gen. *balādēr* (বালদের), dat. and acc. *balādḱé*, voc. *balad*, abl. *balādḱaité*, instr. *baladété*, loc. *baladété*; plural—nom. *baladérá* (বালদেরা), gen. *baladérdigér* (বালদেরদিগের), dat. and acc. *baladérdigḱé*, voc. *baladérá*, abl. *baladérdigété*, instr. *baladérdigété*, loc. *baladérdigété*. Adjectives agree with their nouns only in gender, but not in number and case. The sign of the feminine is *a*, and sometimes *ī*. Bangālī is the only modern language of India which

has special forms for the comparative and superlative, and they have been borrowed from Sanskrit. The pronoun of the first person singular is *ami*, plural *amrá*; second person singular, *tumi*, plural *tómrá*; third person singular, *séi*, plural *táhhára*. The relative pronoun is *yini* in the singular and *yénára* in the plural. The first ten cardinal numbers are *ék*, *dui*, *tin*, *cári*, *pāc*, *chay*, *sát*, *át*, *nay*, and *dag*. No distinction is made between transitive and intransitive verbs. The present participle ends in *-it*, which receives in the present tense an *é*, making it *-ité*, for euphony. The participle of the aorist ends in *-la*, that of the past in *-ya*. The termination for the future is *-iba*. The different persons are indicated by suffixes. The languages of Assam and Orissa, Assamí and Oriya, are closely related to Bangáli. The former, however, has incorporated many elements pertaining to the speech of the neighboring population of Burmah and Thibet, while the latter has a strong admixture of Arabic.—Nipáli or Nepaulese, the language of Nepal, also possesses many Thibetan elements. The neuter gender has disappeared; the plural is formed by adding *héru*, collection, assembly, and the genitive of nouns is considered an adjective, and has an inflection of its own. The general character of the declension may be seen from the following example: singular, nom: *mánis* (मानिस),

a man, gen. *mániskó* (मानिसको), dat. *mánislái*, acc. *mániskan*, voc. *hé mánis*, abl. *mánisdésivátó*, instr. *mánislé*, loc. *mánisvisémá*; plural—nom. *mánishéru* (मानिसहेरु), gen.

mánishérukó (मानिसहेरुको), dat. *mánishéruleái*, acc. *mánishérukan*, voc. *hé mánishéru*, abl. *mánishérudésivátó*, instr. *mánishérule*, loc. *mánishéruvisémá*. The pronoun of the first person singular is *mā*, plural *hāmihéru*; second person singular, *tā*, plural *timihéru*; third person singular, *tun*, plural *tinihéru*. The relative pronoun is *gun* in the singular and *gunhéru* in the plural.—Kashmiri and Panjābī (Cashmerian and Punjaabee) has embodied many Arabic and Persian elements. Only the masculine and feminine genders are distinguished. Feminines generally end in *nī* or *ānī*. Nouns are declined like the following example: singular—

nom. *ghórā* (घोड़ा), a horse, gen. *ghórédā* (घोड़ेरा), *ghórédā*, *ghórédé*, dat. *ghórétāi*, acc. *ghórénū*, abl. *ghórété*, instr. *ghóréné*, loc. *ghórévóic*; plural—nom. *ghóré* (घोड़े), gen. *ghóríāddā* (घोड़ियांदा), *ghóríāddā*, *ghóríāddé*, dat. *ghóríāttāi*, acc. *ghóríānnā*, abl. *ghóríātté*, instr. *ghóríānné*, loc. *ghóríāvóic*. The pronoun of the first person singular is *māi*, plural *asī*; second

person singular, *tā*, plural *tusī*; third person singular and plural, *só*. The relative pronoun is *gó* both in the singular and plural. Verbs form the present participle by adding *-ant*, and the past participle by *-ta*.—Sindhi has been maintained in a comparatively close relation to ancient Sanskrit, and is of great importance for the investigation of modern Indian forms of speech. This language also has lost the neuter gender. The plural case is not formed in it as in the other languages by adding some word signifying collection or assembly, but by a genuine case ending *ū*, or sometimes *ā*. The genitive case of nouns is also used here as a sort of adjective admitting of special inflection. Declension is generally according to the following example: singular—nom. *macharu*

(मकर), a gnat, gen. *macharagó* (मकर जो), *macharagí*, *macharagá*, *macharagū*, dat. and acc. *macharakhē*, voc. *é machara*, abl. *macharakhō*, instr. *machara*, loc. *macharamē*; plural—nom. *machara* (मकर), gen. *macharanigó* (मकरनि जो), *macharanigí*, *macharanigá*, *macharanigū*, dat. and acc. *macharanikhē*, voc. *é macharó*, abl. *macharanikhō*, instr. *macharani*, loc. *macharanimē*. Adjectives are put in perfect agreement with their nouns in number, gender, and case. The pronoun of the first person singular is *āū*, *ā*, or *mā*, plural *asī*; second person singular, *tā*, plural *tavhī* or *tahī*; third person singular, *só*, feminine *sā*, plural *sé*. The relative pronoun is *gó* in the singular masculine, *gá* feminine, and *gē* in the plural. There are pronominal suffixes which are probably due to the influence of the Persian. When added to a noun they have the force of a genitive. They are: *mī*, first person singular; *i*, second; *si* or *āi*, third; *sū*, *sī*, or *ū*, first person plural; *va*, second; *ni* or *āi*, third. The first ten cardinal numbers are *hiku*, *ba*, *tē*, *cári*, *pāga*, *cha* or *chaha*, *sata*, *aṭha*, *nāvā*, and *raha*. The corresponding ordinals are *pérhyō*, *bíó*, *tió*, *cóthō*, *pāgō*, *chahō*, *satō*, *athō*, *nāvō*, and *rahō*. The present participle of intransitive verbs ends in *ādó*, of transitive verbs in *īdó*. The past participle is formed by adding *-yá*. Urdu or Hindústānī is a dialect of Hindī, whose origin dates back to the 11th century A. D. It is strongly mixed with Persian and Arabic, and also to some degree with Tartaric Mongolian elements. It is the current administrative language of India, and spoken by all connected with official circles. It was called Urdu from its having been developed in the camps (*urdu*) of the Moslem conquerors of the country. The best authorities believe that it did not take form as a specific variety of Indian speech before the 16th century. It distinguishes a masculine and feminine gender, and the latter is generally indicated by *i*, as *bētā*, son, *bēti*, daughter; *larkā*, boy, *larkī*, girl; or by *ānī*, *nī*, and *nī*, as *bāgh*,

tiger, *bāghnā*, tigress. The plural of nouns in oblique cases is formed by adding *ḥ*; the nominative of masculine nouns remains unchanged if it ends in a consonant or in *ī*, but if in *ā* or *ah* it receives an *ē*. Feminines in *ī* take *ā*, others *ē*. The sign for the genitive is *kā* masculine, *kī* feminine. This case has also the force of an adjective, and its own oblique cases end in *kē*; as *rāgākā bētā*, the son of the king; *rāgākē bētēkō*, to the son of the king. The form of the other cases will appear from the following paradigm: singular—nom. *ādhā*

(*اندها*), a blind man, gen. *ādhēkā* (*اندهی کا*),

ādhēkē, *ādhēkī*, dat. and acc. *ādhēkō*, voc. *ai ādhē*, abl. *ādhēsē*, instr. *ādhēnē*, loc. *ād-*

hēmē; plural—nom. *ādhē* (*اندهی*), gen. *ād-*

hōkā (*اندهون کی*), *ādhōkē*, *ādhōkī*, dat. and

acc. *ādhōkō*, voc. *ai ādhō*, abl. *ādhōsē*, instr. *ādhōnē*, loc. *ādhōmē*. Adjectives always agree with their nouns in gender and case, but not always in number; as *acēhī larḥkī*, the good girl; *acēhē larḥkē*, the good boys; *acēhī larḥkiyā*, the good girls. The pronoun of the first person singular is *maī*, plural *ham*; second person singular, *tū*, plural *tum*; third person singular and plural, *sō*. The relative pronoun is *gō* in both singular and plural. The first ten cardinal numbers are *ēk*, *dō*, *tīn*, *čār*, *pāc*, *čah*, *sāt*, *āth*, *nav*, *das*. The corresponding ordinals are *pahlā*, *dāsrā*, *tīsrā*, *cauthā*, *pācāvā*, *čathvā*, *sāthvā*, *āthvā*, *navā*, *dascā*. The present participle of verbs ends in *ant*, the past participle in *ta*.—Guzarāṭī or Gujarati distinguishes all three genders. Nouns are declined as follows:

singular—nom. *dēv* (*देव*), a god, gen. masc.

sing. *dēvnō* (*देवनी*), gen. fem. sing. *dēvnī*, gen.

neut. sing. *dēvnū*, gen. masc. pl. *dēvnā*, gen.

fem. pl. *dēvnī*, gen. neut. pl. *dēvnā*, dat. and

acc. *dēvnē*, voc. *arē dēv*, abl. *dēvthī*, *dēvēthī*,

instr. *dēvthī*, *dēvēthī*, *dēvē*, *dēvēkarī*, *dēvēka-*

rīnē, loc. *dēvē*, *dēvmā*; plural—nom. *dēvō*

(*देवी*), gen. masc. sing. *dēvōnō* (*देवनी*), gen.

fem. sing. *dēvōnī*, gen. neut. sing. *dēvōnū*, gen.

masc. pl. *dēvōnā*, gen. fem. pl. *dēvōnī*, gen.

neut. pl. *dēvōnā*, dat. and acc. *dēvōnē*, voc. *ahō*

dēvō, abl. *dēvōthī*, instr. *dēvōthī*, *dēvōē*, *dēvōē-*

karī, *dēvōēkarīnē*, loc. *dēvōē*, *dēvōmā*. The

genitive of nouns can thus be employed as

an adjective and made to agree in gender

and number with the substantive. Adjectives

agree with their nouns in gender, number, and

case. The nominative singular masculine ends

in *ō*, feminine in *ī*, neuter in *ū*; the nomina-

tive plural masculine in *ā*, feminine in *ī*, neu-

ter in *ā*. The pronoun of the first person singular

is *hū*, plural *amē*; second person singular,

tū, plural *tamē*; third person singular, *tē*, plu-

ral *tēō*. The relative pronoun singular is *gē*,

plural *gēō*. The first ten cardinal numbers are

ēk, *bē*, *tan*, *čār*, *pāc*, *čha*, *sāt*, *āth*, *nav*, and

das. The corresponding ordinals are *pēhēō*,

bīgō, *tīgō*, *čōthō*, *pācāmō*, *čhatō*, *sātāmō*, *āthāmō*,

navāmō, and *dasāmō*. The present participle

ends in *tō*, *tī*, *tū*. The past participle is formed

by *yō*, *ī*, *yā*.—Marāṭhī also distinguishes three

genders. Nouns are declined as follows: sin-

gular—nom. *dēv* (*देव*), a god, gen. *dēvācā*

(*देवाचा*), *dēvācī*, *dēvāca*, *dēvācē*, dat. and

acc. *dēvās*, *dēvātā*, abl. *dēvāpāsūn*, instr. *dēvānē*,

dēvāna, loc. *dēvāt*; plural—nom. *dēvā* (*देव*),

gen. *dēvācā* (*देवांचा*), *dēvācē*, *dēvāca*, *dēvācē*,

dat. and acc. *dēvās*, *dēvātā*, abl. *dēvāpāsūn*,

instr. *dēvānē*, *dēvāna*, loc. *dēvāt*. Adjectives

end when masculine in *ā*, feminine in *ī*, and

neuter in *a*, and are connected with their nouns

as if they formed a compound word with them.

Number and case are indicated only when ad-

jectives are used as nouns. The pronoun of

the first person singular is *mī*, plural *āmḥī*;

second person singular, *tū*, plural *tumḥī*;

third person singular, masculine *tō*, feminine *tī*, neu-

ter *tē*; plural for the three genders, *tē*. The

relative pronoun singular masculine is *gō*, femi-

nine *gī*, neuter *gē*; plural for the three gen-

ders, *gē*, but the feminine appears sometimes as

gyā. The present participle of transitive verbs

ends in *it*, of intransitive verbs in *at*. There is

another form ending in *tā*. The past partici-

ple of transitives ends in *ilā*, of intransitives

in *alā*.—DRAVIDIAN LANGUAGES. Excepting

Cingalese, or Singhalese, the language spoken

on the island of Ceylon (which, though possess-

ing some points of similarity with the Dravidian

languages, is nevertheless treated by several

eminent scholars as a language entirely distinct

by itself), the Dravidian group must be divided

into five sections or languages, to which may

be added a sixth, comprising the idioms still

imperfectly known and spoken by the races

which occupy the innermost parts of the moun-

tainous regions. The Tamil language is the

Sanskrit of the whole group. It is spoken

mainly in the so-called Carnatic, or the eastern

coastland below the Ghauts of Palicat as far

as Cape Comorin, and from the Ghauts to the

bay of Bengal. It is heard also in the West-

ern Ghauts and in the northern portion of

Ceylon. There are two dialectical variations

of it. One is the so-called classic or Sen-

Tamil, and the other the colloquial or Kodun-

Tamil. The next highest rank must be assign-

ed to Telugu, formerly called Gentoo. It was

once spoken as far N. as the Ganges, but now

reaches only from Cicacole on the E. coast to

Palicat, and thence as far as Mysore. The

next in order, and nearest related to the two

preceding, is Canarese, whose territory extends

over Mysore and the eastern districts of the

Nizam as far as Beder; it is spoken also in

the district of Canara, on the Malabar coast.

The fourth language is Malayālam or Mala-

yalma, spoken on the coast of Malabar, on the

western side of the Ghauts, between Mangalore and Trivandrum. The fifth and least represented language is Tulu or Tuluva, formerly spoken in Canara, now only in the vicinity of Mangalore, and rapidly dying out. The speech of the Todavars, Kotars, Gonds, Koos, and other races occupying the mountains, is expected to show on further acquaintance an intimate relation with these languages. Max Müller considers the Dravidian languages as a branch of the Uralo-Altaiic, Mongolian, or Turanian; but Fr. Müller and other great authorities consider them a totally distinct and primitive division of human speech. These languages are written in peculiar graphic systems, which are derived like those of the Aryan languages of India from the Dêvanâgari alphabet, but less directly, coming through the Kistnah and Nerbudda characters. The sounds may be grouped in Tamil as follows:

	Tamil.		
	Surd.	Sonant.	Nasal.
Gutturals	க k,	க g,	க n̄.
Palatals	ச c,	ச j,	ச ñ.
Cerebrals, I. . . .	ட t,	ட d,	ண n.
Cerebrals, II. . .	த t,	த d,	ண n.
Dentals	த t,	த d,	டு n.
Labials	ப p,	ப b,	ம m.
Liquids	ய y,	வ v,	ர r,
	ல l,	ள l,	ழ z.
Sibilant	ச s.		
Vowels	அ a,	ஆ á,	இ i,
	ஈ ē,	உ u,	ஊ ū,
	எ e,	ஏ é,	ஐ o,
	ஔ ó,	ஔ au,	ஔ i.

The cerebrals are pronounced with a decided palatalization. The Tamil characters probably represent the oldest of the south Indian graphic systems. In all the Dravidian languages, but especially in Tamil and Malayálam, there is the peculiar law of beginning with surd sounds every word and syllable following one that is closed; and of beginning with sonants every syllable which succeeds another that is open, or that is closed with a nasal or a liquid sound. Tamil adds to this the difficulty of employing the same sign either as a surd or a sonant, leaving it to the reader to decide how it is to be pronounced. Another difficulty arises from the fact that the Dravidian languages absorbed many Aryan words belonging to different periods of the ancient and modern Indian languages. Some of these words were appropriated without alteration, called *tatsama* by native grammarians, and others have been assimilated with Dravidian forms, called *tadbhava*. As the Dravidian alphabets do not represent

all the Indian sounds, it was found necessary either to invent others, which was done in Telugu, Kannadi, and Malayálam, or to change the words so that the alphabet would suffice, which is done in Tamil. Originally, therefore, the Dravidian languages made use only of the number of characters still employed in Tamil; but at present Telugu, Kannadi, and Malayálam have a system of signs which represent also the sounds of the Aryan languages, and which may be grouped in a similar manner. Canarese characters are similar to the Telugu; hence we subjoin only the latter and the Malayálam:

		Telugu.			
Gutt.	క k,	ఖ kh,	గ g,	ఘ gh,	ఙ n̄.
Pal.	చ c,	ఛ ch,	జ j,	ఞ jh,	ఞ ñ.
Cer.	ట t,	ఠ th,	డ d,	ఢ dh,	ణ n.
Dent.	త t,	థ th,	ద d,	ధ dh,	న n.
Lab.	ప p,	ఫ ph,	బ b,	భ bh,	మ m.
Liq.	య y,	ర r,	ల l,	ల v.	
Sib. and asp.	శ s,	ష s,	స s,	హ h.	
Vowels . . .	{	అ a,	ఆ á,	ఇ i,	ఈ ē,
		ఊ u,	ఋ á,	ఎ e,	ఐ ó,
		ఔ o,	ఔ ó,	ఋ au,	ఋ i.
		Malayálam.			
Gutt.	ക k,	ഖ kh,	ഗ g,	ഘ gh,	ങ n̄.
Pal.	ച c,	ഛ ch,	ജ j,	ഞ jh,	ഞ ñ.
Cer.	ട t,	ഠ th,	ഡ d,	ഢ dh,	ണ n.
Dent.	ത t,	ഥ th,	ദ d,	ധ dh,	ന n.
Lab.	പ p,	ഫ ph,	ബ b,	ഭ bh,	മ m.
Liq.	യ y,	വ v,	ര r,	ല l.	
Sib. and asp.	ശ s,	ഷ s,	സ s,	ഹ h.	
Vowels . . .	{	അ a,	ആ á,	ഇ i,	ഈ ē,
		ഉ u,	ഊ ū,	എ e,	ഐ ó,
		ഔ o,	ഔ ó,	ഋ au,	ഋ i.

These systems enable the Telugu, Kannadi, and Malayálam to give Indian words in their own orthography, while Tamil must transform them according to the necessities of its insufficient alphabet. A sentence is in all the Dravidian languages an absolute whole. The words are closely connected, and the junction of vowels or consonants, vowel and consonant, or consonant and vowel, at the end and beginning of two words, produces various euphonic changes. The accent, however, remains always on the root syllable, which is in all cases the first syllable of a word. The parts of speech may be reduced to only two groups of nouns and verbs. There is hardly what is called a gram-

matical gender, excepting in the pronoun of the third person; which belongs mostly to the verb. Nouns are distinguished, however, as belonging either to the higher or to the lower caste, the one comprising rational and the other irrational beings; men, gods, demigods, spirits, and the like, forming one group, and animals, inanimate objects, and subjective ideas, the other. Singular and plural numbers are distinguished, the latter by means of high- or low-caste suffixes. The former was originally called *mār*, and is now chiefly employed as an honorific plural; otherwise it is reduced to *ar*, *ār*, *ir*, and *īr*, appearing in Telugu and Kannadi as *aru*, *uru*, *ru*, *ri*, *āru*, and *ēru*. The latter was originally called *kaḷ* and *gaḷ*, as still clearly seen in Tamil and Malayālam. In Canarese it is *gaḷu*. The cases are indicated by means of suffixes. The declension of nouns is shown in the following examples: 1. *Tamil*. Singular—nom. *rāyaṅ* (ராயன்), a king, acc. *rāyaṅi*, gen. *rāyaṅudīya* (ராயனுடைய), dat. *rāyaṅukku* (ராயனுக்கு), abl. *rāyanilirundu*, instr. *rāyaṅāl*, loc. *rāyaṅiḍattil*; plural—nom. *rāyar* (ராயர்), acc. *rāyarī*, gen. *rāyarudīya* (ராயருடைய), dat. *rāyarukku*, abl. *rāyarilirundu*, instr. *rāyarāl*, loc. *rāyaril*, *rāyaridattil*. 2. *Telugu*. Singular—nom. *gurramu* (గుర్రము), a horse, acc. *gurramunu*, gen. *gurramuyokka* (గుర్రముయొక్క), dat. *gurramuku*, *gurramunaku*, instr. *gurramucēta*, loc. *gurramulō*; plural—nom. *gurramulu*, acc. *gurramulanu*, gen. *gurramula*, dat. *gurramulaku*, instr. *gurramulacēta*, loc. *gurramulalō*. 3. *Malayālam*. Singular—nom. *mala*, a mountain, acc. *malayē*, gen. *malayutē*, dat. *malekka*, abl. *malayilnanna*, instr. *malayāl*, loc. *malayil*; plural—nom. *malakal*, acc. *malakalē*, gen. *malakalutē*, dat. *malakalukka*, abl. *malakaliloninna*, instr. *malakalāl*, loc. *malakalil*. 4. *Kannadi or Canarese*. Singular—nom. *maravu*, a tree, acc. *marava*, gen. *marada*, dat. *marakke*, abl. *maradadeseinda*, instr. *maradinda*, loc. *maradalli*; plural—nom. *maragaḷu*, acc. *maragaḷa*, gen. *maragaḷa*, dat. *maragalige*, abl. *maragaladeseinda*, instr. *maragalinda*, loc. *maragalalli*. 5. *Tulu*. Singular—nom. *mara*, a tree, acc. *marana*, gen. *marada*, dat. *maraka*, instr. *marad̄da*, loc. *marada*; plural—nom. *marakulu*, acc. *marakuluna*, gen. *marakula*, dat. *marakuluka*, instr. *marakuludda*, loc. *marakuluda*. Adjectives remain always unchanged in the Dravidian languages, and always precede their nouns. Personal pronouns, however, are capable of inflection. The pronoun of the first person singular, nominative, is in Tamil *nāṅ*, Telugu *nēnu*, Kannadi *nānu*, Malayālam *nān*, Tulu *yān*; plural, Tamil *nām*, Telugu *mēnu*, Kannadi *nām*, *ām*, and *nāvu*, Malayālam *nān*, Tulu *namma*. In Sen-Tamil the suffix *gaḷ* is added to produce a pure plural form; hence *nāṅgaḷ* instead of *nām*. The first ten cardinal numbers in Tamil are *oṅḍu*, *irāṅḍu*, *mūṅḍu*, *nālu*, *iṅḍu*, *āḍu*, *ēḷu*, *eṭṭu*, *oṅḍadu*, and *pattu*. In Telugu there is no

word for one; the others are *rendu*, *mādu*, *nāḷugu*, *aidu*, *āru*, *yēdu*, *yenimidi*, *tommidi*, and *padi*; in Kannadi the ten are *ondu*, *eradu*, *māru*, *nāḷku*, *aidu*, *āru*, *ēḷu*, *eṭṭu*, *om bhattu*, and *hattu*; and in Malayālam, *onna*, *raṅṅa*, *mānna*, *nāḷa*, *aṅṅa*, *āru*, *ēḷa*, *eṭṭa*, *oṅḍata*, and *patta*. The most peculiar constituent of the Dravidian languages is the verb, which is a mere compound of a form of the noun with a personal pronoun. Caldwell says of it: "When case signs are attached to a root, or when, without the addition of case signs, it is used as the nominative of a verb, it is regarded as a noun; the same root becomes a verb without any internal change or formative addition, when the signs of tense and the pronouns or their terminal fragments are suffixed to it." Further on he says: "The structure of the Dravidian verb is strictly agglutinative. The particles which express the ideas of mood and tense, transition, intransition, causation, and negation, together with the pronominal fragments by which person, number, and gender are denoted, are annexed or agglutinated to the root in so regular a series and by so quiet a process, that generally no change whatever, or at most only a slight euphonic change, is effected either in the root or in any of the suffixed particles. As the Dravidian noun has but one declension, so the Dravidian verb has only one conjugation and but very few irregular forms."—Cingalese or Singhalese, the language of the Elu, the original inhabitants of Ceylon, incorporated a large number of Pāli and Sanskrit words, while the modern modifications of it are tinged with Malay. (See CINGALESE LANGUAGE.) The Elu alphabet has 34 consonants and 12 vowels. This alphabet may be classified as follows:

Gutt.	ක k, ඛ kh, ග g, ඝ gh, ඞ ṅ.
Pal.	ච c, ජ ch, ජ ජ, ඞ gh, ඞ ṅ.
Cer.	ච t, ඩ th, ඩ d, ඩ dh, ඞ ṅ.
Dent.	ඞ t, ඞ th, ඞ d, ඞ dh, ඞ ṅ.
Lab.	ප p, ච ph, බ b, ඞ bh, ඞ m.
Semi-vow-	ය y, ර r, ල l, ඞ l̄, els..... ඞ v.
Sib. and asp.	
Vowels ...	ඞ a, ඞ i, ඞ u, ඞ e, ඞ ai, ඞ o, ඞ au, ඞ á, ඞ í, ඞ ú, ඞ é, ඞ ó.

There is no grammatical gender, though grammarians distinguish between male and female, restricted however to animate beings, and even this is very vaguely applied. Feminines are indicated by the Sanskrit termination *i*, *innī*, or *inna*. The plural is formed either by substituting *ō* for the final *d*, or by dropping the final vowel, and further by one of the four affixes

varu, lā, hu, and val. There are eight cases, and nouns are inflected as follows: singular—nom. *purusayā* (*ପୁରୁଷୟା*), a man, acc. *puru-*

sayā, voc. *purusayō*, gen. *purusayāgē*, dat. *purusayāta*, abl. *purusayāgen*, instr. *purusayāvisin*,

loc. *purusahukerehi* (*ପୁରୁଷହୁକେରହି*);

plural—nom. *purusayō* (*ପୁରୁଷୟୋ*), acc.

purusayan, voc. *purusayeni*, gen. *purusayangē*, dat. *purusayanā*, abl. *purusayangen*, instr.

purusayanvisin (*ପୁରୁଷୟାନ୍‌ବିସିନ୍*), loc.

purusayankerehi. This inflection of nouns varies according to the final vowel. Adjectives precede the substantive, and remain unchanged. The comparative is formed by *vadā, vedīya, or vedīyen*, and the superlative by *atī* or *itā*, which particles are always prefixed to adjectives. In comparing two objects, the object compared with another is put in the dative. The pronoun of the first person singular is *mama*, plural *api*; second person masculine singular *tō*, plural *topi*; feminine singular *tī*, plural *tīlā*. But there are several other forms of this pronoun in use, which are employed according to the rank of the person addressed. The pronoun of the third person singular is *ohu* or *ū*, plural *ūlā*; the abbreviation *ū* being mainly used in formal discourse. The first ten cardinal numbers are *ēka, deka, tuna, hatara, paha, haya, hata, ata, nevaya* or *namaya, and dahaya*. Ordinals are formed by suffixing *veni*. Verbs are divided into transitives and intransitives, and are distinguished as active and passive. The tenses, of which there are eight, viz., two of the present, an imperfect, perfect, past perfect, and future, are formed by means of participial formatives and auxiliaries. Number and person are indicated merely by the personal pronouns used in conjunction with the verbs.—See *Reise der Novara*; *Linguistischer Theil*, by Friedrich Müller (Vienna, 1867), and *Ethnographischer Theil*, by Müller and Seherzer (1868); Beames, "Comparative Grammar of the Modern Aryan Languages of India" (London, 1872 *et seq.*); and the journals of the royal Asiatic society of Great Britain and Ireland, and of the royal Asiatic society of Bengal.

INDIA, Religions and Religious Literature of. In the present state of uncertainty in regard to their chronological order, it seems advisable to treat the comparatively few monuments of the literature of India with which we have become acquainted in connection with the various periods of the religious history of the country for which they form the sources of our information. The character of the first two periods is depicted in several writings which may be classified as monuments of Vedic and of Sanskrit literature. The first embraces the hymns of the Veda, the Brāhmanas, and

the Sūtras. The Veda-Sanhitās or Veda texts exist in four collections: Rig-Veda, Sāma-Veda, Yajur-Veda, and Atharva-Veda. The Rig-Veda is the largest and most valuable collection. The hymns are grouped in it chiefly according to their asserted authors. They comprise 1,028 *sūkta*, hymns, and 10,580 *rik*, verses, which are divided into 10 *mandala*, circles or books. The Sāma-Veda-Sanhitā is a body of verses culled from the hymns of the Rig-Veda, along with a few others, arranged into forms suitable for chanting. It is supposed to be older than the compilation of the Rig-Veda, as it does not contain any of the verses in the latter which appear to be of a late date. The Yajur-Veda gives the verses and formulas of words to be recited during the progress of the ceremonies attending sacrifice. There are two editions of it, which however differ only in arrangement. The black Yajur-Veda or Taittirīya-Sanhitā gives also dogmatic explanations, while the white Yajur-Veda or Vājasaneyi-Sanhitā contains only the verses of the ritual. The Atharva-Veda seems to be a continuation of the tenth *mandala* of the Rig-Veda; it is a collection of hymns of various date and character, but predominantly superstitious. The Brāhmanas furnish descriptions of the ceremonies prescribed in the Sanhitās, and numerous legends bearing on them; but they are full of repetitions. They have an addendum of philosophical speculations, called *Āraṇyaka*, forest portion, probably from the fact that philosophers generally lived as hermits in the woods. A portion of the *Āraṇyaka* is called *Upanishad*, session, and contains speculations depicting the Brahmanical system of pantheism. The Sūtras are collections of practical rules respecting matters of ceremony and worship. Such are especially the *Ṇrauta-Sūtras*, or the revealed, while the *Grihya-Sūtras*, or the domestic, seem to be oral traditions giving rules of conduct and general behavior. Sūtras which explain the language, mythology, or astrology of the Vedas are called *Vedāngas*, or members of the Vedas. Those which attempt to analyze the philosophy of the Vedas bear the name of *Vedānta*, or purpose of the Vedas. Linguistically considered, these last belong to the next, or Sanskrit period, distinguished by a later character of the language. Prof. Max Müller divides the interval in which the books enumerated appeared into four periods. The first of these, the *Chhandas* period, or the period of spontaneous poetic productiveness, he computes to have lasted from 1200 to 1000 B. C., and during that time the most ancient of the Vedic hymns were composed. The second, the *Mantra* or "sacred formula" period, comprises the next two centuries, and its hymns bear traces of the growth of a sacerdotal spirit and system. The third or Brāhmana period closes at 600 B. C., and the fourth or Sūtra period is assigned to the time subsequent to it, and ending 200 B. C. Prof. W. D. Whitney, however, holds that this chronology

is "a mere conjectural hypothesis, which is not fairly entitled even to temporary and provisional acceptance." Among the works belonging to the Sūtra division are sometimes reckoned the Prātiçākhyas, which are treatises explaining the phonetic peculiarities of the text of the hymns, and the Anukramanis, which are indices to the texts, and state the author, theme, length, and metres of each hymn. During the period that Sanskrit gradually ceased to be the national tongue, there seem to have appeared also a number of works which are of considerable importance for the history of the country as well as for its religion. They are the Dharmācāstras or books of laws, 56 in number, of which the famous laws of Manu, which the Hindoos still regard as the standard of their public and social law, are probably the oldest. In its present form, and from the internal evidence of its opposition to Buddhism, this work is supposed to date from about the 4th century B. C. It lays down the rules which are to guide persons of various castes in their behavior toward each other, and contains a multitude of cosmogonic speculations. The chief monuments of this age, however, are two long epics or Itihāsas. One is the Mahābhārata, which describes the feuds between the Pāndavas and Kauravas, royal races, descendants of the Bhāratas. In its present form it consists of more than 100,000 double verses or *ślokas*, of which the best known portions are the Nala and the Bhagavad-Gītā. Lassen places the redaction of this epic between 400 and 350 B. C., Benfey in the 3d century, and Weber in the last two centuries before our era. The other epic is the Rāmāyana, which describes in about 24,000 double verses the great deeds of Rāma, a prince of Ayōdhya or Oude, resulting in the extension of Aryan dominion over the Deccan and Ceylon. Rāma is represented as an incarnation of Vishnu, and Brahmanic asceticism and hierarchy are dominant features in it. As the Rāmāyana contains no allusions to Buddhism, Lassen considers it the older of the two epics; but Duncker assigns it to a later date, as it does not describe an equally well defined priesthood. It is generally believed that both epics were originally oral productions; but they are ascribed to special poets. The Rāmāyana is said to have been sung by Kuça and Lava, the sons of its hero, who had learned it from the Brahman Vālmiki. Their names were subsequently contracted into Kuçilava, which came to be applied to any bard or actor. The Mahābhārata is ascribed to Vyāsa, who is said to have been an eye-witness of the events. Vaiçampāyana, his pupil, recited it for the first time at the great serpent sacrifice of the king Janamējaya. Sūta Ugrāçravas recited it a second time at the sacrifice of Çaunaka. The narratives of the Mahābhārata and Rāmāyana are continued by the Purānas, which are of a much later date, and which are written in the interest of religious sects subsequently developed; they must therefore be spoken of

after an account of the earliest forms of the religion of India.—The Rig-Veda states in several passages that the gods are 33 in number, though according to its own showing this number is far too small. There are three classes of gods: of the heavens, the air, and the earth. The separation of the heavens and the air or atmosphere is based on a distinction between light and air. The home of the gods of light is beyond those of the air. Light is not considered as dependent on the solar body, but as an independent and eternal force. The domain of the gods of the air lies therefore between the earth and the source of light, and their main office is to provide a free passage for the light and rain which the gods furthest off wish to pour upon the earth. The Hindoo idea of what is divine seems to attach itself to that of light. The word for god is *dēva*, which comes from the root *div*, meaning to shine or glitter. Sūrya is the principal godhead in heaven, Vāyu or Indra of the air, and Agni of the earth. The gods of heaven never appear as sensual and mythological as those of the other two spheres. There are some whose symbol of divinity is not limited to a single object of nature; such is Aditi, who is either a god or a goddess, and whose sons are the Adityas. This divinity is rarely mentioned in the older Vedas as a personification, but generally as the abstract idea of the eternal and infinite. The sons of Aditi are Mitra, Varuna, Aryaman, Bhaga, Daksha, and Ança; but in some instances as many as seven, eight, and even twelve Adityas are mentioned. Without the distinction being always clearly maintained, it seems that Mitra is the heavenly light of the day, and Varuna of the night. The latter sometimes appears as the lord of all three regions. The sun has several names. Sūrya is the usual designation, though Savitri also occurs frequently in the Vedas, but he is generally coupled only with the golden and glorious attributes of the sun. Gods of heaven often represent only special phenomena of light. The Açvin are a problematical pair, gods of the earliest daylight. Very circumstantial stories are told of the wonders they have done in healing and saving. Ushas, the dawn, is the beautiful virgin who opens the gate of heaven, chases away the night, and invigorates man and beast. The beneficent effects of solar light are represented by Pūshan. He protects and multiplies all that man owns, guides him on his journeys, protects him against robbers and thieves, and directs departed souls. His chariot is drawn by goats, and he carries a goad. He is sometimes invoked in conjunction with Indra, but has little in common with the gods of the sphere of the air. Vishnu must also be reckoned as a sun god. His name is seldom mentioned in the Vedas. He has passed through the whole universe with only three steps, and has taken his domicile near Indra. He has given the earth to man, the descendant of Manu, as his inheritance. The unbroken order

of the world is principally due to him. In the Vedas he is the friend of Indra, whose place in the worship of the Indian people he afterward usurped.—In the sphere of air there are demons, dark beings, Rakshasas and Asuras. The other gods of this region have to battle with them in order to chase them away. They receive new vigor for these contests from the sacrifices which man offers up to them. In course of time they became more popular than the Adityas, but they grew also more humanlike than they. Their chief was Indra, the god of thunder storms. Though the Maruts and Vishnu were at his side, it was he alone who conquered the demons, and therefore it is he who shields man in battle. His principal antagonist among the demons is Vritra, or he who covers up or hides. This Vritra disposes the clouds so that the waters of heaven cannot descend upon the earth. Pani imprisons the waters like cows in the caverns of the rocks, but Indra liberates them and makes them flow upon man over the corpse of Vritra. Indra moves about in a golden chariot, drawn by reddish horses with golden manes and hair like the plumes of a peacock. Prayer harnesses Indra's horses; Tvashtri, the artist of heaven, fashioned a thunderbolt for him; and heaven and earth, and even Tvashtri himself, tremble when his thunder rolls. The gods of wind and rain compose Indra's suite; they are Vāyu, the Maruts or Rudras, and Rudra himself. Vāyu is the wind, but little else is known of him. He was succeeded in the veneration of the people by Vāta, who is the soul of the gods and the source of the world. There are 27 or three times 60 Maruts or Rudras, sons of Rudra and Priçni, the kind gods of the rain; they form Indra's armed body guard, have iron teeth and roar like lions, and they sometimes darken the sun, but always remove their curtains after a while. Rudra, the strongest of them all, roars the loudest; he is the god of storms, whom man must fear, and whose sacrifices must not be neglected. He is besought to spare the lives of the members of the family, and also of the cattle. In course of time he came to be regarded as the forerunner of Siva (Çiva).—The third division, that of the gods of the earth, is the pantheism of the Hindoo religion. Light is the revelation of the divine, and as far as man can produce light, so far can he attain toward the divine. Agni, the god of fire, was let down from heaven by Mataricvan, the messenger of Vivasvat. The Rishi (pious) Atharvan found him concealed in wood, and by friction induced him to come out. Indra probably begat him between two stones, or perhaps the aurora gave birth to him, or he may be a child of Indra and Vishnu. His origin is threefold: of heaven, of earth, and of air. He has a twofold activity. He is a messenger between the gods and man, not as a low subordinate, but as a viceroy and guardian of the heavenly light on earth; he pierces the

demons with his arrows, and he keeps man from evil; in a word, he is the protector of human beings. His other office is to act as messenger between man and the gods; whenever a fire is lit, the gods must come, for Agni calls them; what the gods do for man is due to his intercession. The consequence was that soon the merits of Indra came to be those of Agni; he became the Vritra-killer. Sôma is also a god. It is a beverage prepared from the plant *asclepias acida* or from *sarcostemma viminalis*; the juice of these plants was fermented, mixed with milk and flour, and offered to the gods. It was the hidden fire, its intoxicating power, which man adored. Sôma lends immortality as well to man as to the gods. His works are as great as those of Agni, for even Indra must first be intoxicated to gain strength to kill Vritra. The gods were thus considered to be in need of the offerings of man to carry out their purpose. In fact, without prayer and sacrifice the gods cannot rule the world. Prayer necessitates their fulfilling man's wishes. Concentrated devotion and penance are mightier than all the gods, and hence the priest, the hermit, the devotee, and the wise are greater and more powerful than the gods themselves. This is the key of Brahmanism. The Vedic hymns speak also of minor gods of nature, like Trita and Sarasvatî, the goddess of the river of that name. The Sindhu, or Indus, is the most impetuous of them all. The Asparasas are female spirits of the air, much to be feared; but like the nymphs of the Greeks they often bring joy and happiness. The great Veda gods must have wives, and accordingly the names Indrâni, Agnâni, Varunâni, Açvini, and Rodasi occur in the hymns. Lakshmi appears in later times as the wife of Vishnu, and acts as a goddess of fortune. The Ribhus are men who have been raised to the nature of gods on account of their great piety. The Atharva-Veda mentions a few names which seem to represent similarly deified personifications. Every object used in sacrificing was considered in some degree divine, and hence the Brahmans came to be looked upon as the real gods of the earth. Brahmanaspati or Brihaspati, the god of prayer, was subsequently turned into the great god Brahmâ. His works are sometimes ascribed to Indra, and also to Agni and Sôma; but he is quite as often said to be the father of the gods. Prayer and sacrifice have a creative power, and thus Brahmanaspati, the personified lord of prayer, is considered to be the father of the gods, or the pantheistic principle of the world. Vâch, the goddess of the word or of speech, plays a similar part. The word, whether spoken by man or by the gods, has also a creative power. Similarly Prâna, life or breath, Kâma, love and desire, Kâla, time and the producer of heaven and earth, and Purusha, the ideal man or the spirit of the world, appear in the Vedas as creative principles. Hiranyagarbha, the golden-wombed, and Prajâpati, the lord of creatures, represent the creator as a

personified god. The two names were originally, it seems, epithets of Savitri, the god of the sun, and they reappear subsequently as epithets of the god Brahmá.—The Vedas adhere to no one settled account of the creation. Its existence is generally attributed to the power of sacrifice brought by the gods. It is Purusha, man as a representative of humanity, the ideal man or the spirit of the world, who takes the place of the sacrificial animal, and Indra and Agni arise from him. This is the account given in the Purusha-Súkta of the Rig-Veda. Another hymn of the Rig-Veda gives a more philosophical reason for the existence of the world. Here it is religious meditation which produces it. First was formed the desire, or *káma*, love, which was the first seed. Fire is the creative element as well in the soul of the world as in the soul of man, and it is love, *káma*, that calls it forth and causes it to create. Two names, Yama and Manu, appear as those of the first man. Yama is the first man who died, and he shows the dead the way into the other world, where he rules. Manu is the first ancestor of mankind; he is Father Manu, and the Aryans are his people; it is he who introduced the rite of sacrifice. The gods nourish and protect him, and Vishnu has assigned to him the earth as his dwelling place. In later times his name is coupled with the legend of the flood, but there are no indications of such revolutions of the earth in the Veda-Sanhitás. Yama and Manu are sons of Vivasvat, one of the Adityas, and of Saranyu, the immortal daughter of Tvashtri. Yama takes the deceased into a world which is as sensual as the Mohammedan paradise, and where they feast with the gods and drink Soma. It is Agni, the god of fire, who in consuming the body recreates it into a celestial form, and it is Soma who gives it immortality. The people must worship their ancestors, for they are not dead, but live with the gods, who share their power with them. There is little in the Vedas to show that the dead were ever supposed to be punished, unless they were hostile races or personal enemies.—The worship of the gods was at first entirely in the hands of each family. There were no temples. Sacrifices were offered under the open sky or at the family hearth. Agni could call the gods wherever his fire was burning; this was fed with clarified butter, of which he was fond. Soma was carefully prepared according to numerous prescriptions. Colebrooke denies that the ancient Aryans offered also human sacrifices; but German scholars, as Weber and others, think that it admits of no doubt. Sacrifice was neither a thank offering nor a sin offering; it was a contract between man and the gods, and the latter were obliged to fulfil the wishes of the former whenever a sacrifice was offered. If any fault had been committed in the ceremony of sacrificing, so that the gods would not accept it, it was simply repeated. The light thrown by the Vedas on the re-

ligious constitution of the ancient Aryans reveals that the poets of the hymns were not all of a priestly caste; but subsequently they were all Brahmans, and the king Viçvámitra, who had composed a number of hymns, including the celebrated Gáyatri, was specially raised to the dignity of a Brahman by a later legend, in order to account for the fact of his having been able to write poems. The Rishi, the pious, Kavi, the wise, and Muni, hermits of old, were therefore not all priests. But the Brahmans very soon formed a special caste. Each sacrifice needed a *hótri*, or caller, who recited portions of the Rig-Veda; an *adhvaryu*, or sacrificer, who performed all the work connected with it; and a Brahman, who watched that all was done properly and in order, and who understood how to right every mistake committed. The Brahman was therefore the high priest, who had the power and wisdom to compel the gods to fulfil all requests. The Bráhmanas were his successors, who came to be regarded as gods upon earth. The personal gods Indra, Rudra, Savitri, and others, were too poetical to be very real in the hearts of the ancient Hindoos. A need was felt for a more substantial authority, and the priests usurped it, and formed the Brahmanical system of castes, which made them like gods themselves. This opens the second period in the history of the Indian religions.—It is noteworthy that in spite of the complete penetration of Aryan culture over the whole of the Indian peninsula and even Ceylon, the Hindoos failed to establish a vast and powerful empire. It seems that the conquests told in the Rámáyana and the Mahábhárata were rather religious than political. When the Aryans mingled with the native population of the peninsula, they held a superior position among them from mere distinction of color. The Sanskrit for caste is *varna*, which originally signified color. The Sudras (Çúdras) therefore form only what Max Müller has called an ethnological caste. They are the dark prior occupants of the land of the Ganges, whom the light-complexioned race considered inferior to themselves. The Vedic books divide the entire Indian population into four castes, but this number is really in comparison as much below the mark as the 33 gods have been found to be. Manu's book of laws states that there were 16 mixed castes, besides the four principal ones. These were, besides the Sudras already mentioned, the Brahmans, Kshatriyas, and Vaisyas (Vaiçyas). The Brahmans were to read and teach the Veda, offer sacrifice, conduct the ceremonies of the sacrifices made by the people, and to receive and make gifts. The Kshatriyas were to protect the people, do charity, offer sacrifice, read the holy scriptures, but without teaching them, and control their desires. The Vaisyas were to raise cattle, cultivate the land, carry on trade, give alms, sacrifice, and learn to say prayers. The Sudras had but one duty, that of doing service to the other castes. The majority of the minor or

mixed castes are names of professions and trades, of which some were indicated by the names of the cities or districts in which they were most largely represented and famous. Thus the caste of singers, who descended, as Manu states, from a Vaisya and a Kshatriya woman, are called Māgadhās, evidently because Māgadhā was at one time the home of the most famous singers. These trades and professions stood in various degrees of esteem, and their origin was accordingly stated to be from various unions between higher and lower castes. The aboriginal population was also gradually classified according to the Aryan system, which gave rise to the other division of unclean castes, whom Europeans call pariahs, from the name of a small Tamil caste of this grade with whom they came most in contact. It is not to be supposed that the castes were established without struggle on the part of those who were reduced to inferiority. For a time kings, nobility, and priests must have worked hand in hand to subjugate the people. The legend of the Paraçu-Rāma shows that the Brahmins did not gain superiority over the Kshatriyas without bloodshed. —Turning to the changes produced in the religious ideas of the Hindoos during this period, it is seen that the Vedic pantheism was gradually absorbed by the one Brahma, and that the character of Hindoo worship is decidedly ascetic. Speculation is no longer intent on solving the mystery of the origin of the world, but on devising a process by which the world is to return to the Brahma from which it emanated. This is the point of contact between Brahmanism and Buddhism. Brahma, in the neuter gender, is an impersonality, the sum of all nature, the germ of all that is, the one that embraces everything. The Kēna or Talavakāra Upanishad says of it: "Eye, tongue, mind, cannot reach it; we comprehend it not; we cannot teach it to any one; it is other than all that is known and all that is unknown." Unmeaning words are therefore applied to it. One of them is the mysterious syllable *ōm*, the wonderful trinity of sounds. A Sanskrit *ō* is a diphthong, and by giving it a nasal utterance it sounds like *ōm*; hence it has three letters, but only one sound. The Māndukya-Upanishad is entirely filled with explanations of this little word. Among others it says: "Om is immortal. Its unfolding is this universe, is all that was, is, and shall be. Indeed, all is the word *ōm*; and if there is anything outside of these three manifestations, it is also *ōm*. . . . For this all is Brahma; this soul is Brahma. This soul has four existences." A is its waking condition, U its dreaming, M its sleep, and the whole is its entire existence. Brahma as the abstract principle of the world reappears in a concrete mythological form as the god Brahmā, the Vedic Brahmanaspati. He is pictured with four heads, probably as lord of the four regions of the world. He is Prajāpati, the lord of all creatures, and Hiranyagarbha,

the golden-wombed, the lord of the sun. Below him are the Lōkapālas, stationed at the eight corners of the world to ward off the evil spirits, the Asuras; they are Indra, Agni, Varuna, Sūrya, Chandra or Sōma as god of the moon, Vāyu, Yama, and Kuvēra. The Vedas do not mention the last, who was originally a man, but who is now a god of wealth, as a reward for his great humility to the Brahmins. Brahmā's wife is Sarasvatī, who has ceased to be the goddess of the river, and is now goddess of order, harmony, poetry, oratory, language, and all intelligence. She has absorbed the attributes of Vātch, and is invoked for the instruction of children. She is depicted with a book or a musical instrument in her hand. It is still believed that prayer and sacrifice called the world into existence, but that existence has no special purpose; indeed, it is of evil, for evil came into the world with the world. As it is impossible that there ever can be a sinless world, so every pious person desires to be taken out of it, and to be relieved of his personal existence. The bright and happy Veda religion has thus been transformed into a gloomy meditation on the wretchedness of human life. Fatalism has come upon the Hindoo people, and they say, "Man's destiny is written on his skull." This laid the basis for astrology, and even Manu's exclusion of astrologists from the sacrifices failed to root out the belief in predestination. A natural consequence was a further development of the doctrine of the transmigrations of the soul. Man was oppressed by the numerous distinctions of caste, and he was taught to consider them as part of the system of the world. Every creature descended from Brahmā had to pass again through all the previous stages of his present existence in order to reach Brahmā again. Manu says: "Man is born according to his deeds, ignorant, dumb, blind, deaf, deformed; whoever has not done penance for his deeds will receive his punishment at his birth." Thus one who stole fruit would be a monkey; one who stole a horse, a tiger; one who stole balm, a rat. When transformation into beasts or plants is not an adequate punishment, the evil doers are sent into one of the eight hells, each of which is more tormenting than the other. Hell is not an eternal punishment, but thousands of years of pain hardly suffice for a complete abolition. When this is attained, then begins the ascending scale of transmigrations, which reach to Brahma; but it is possible that in the renewed existence as a human being man's sins are again so great that he must be thrown back to hell. Manu ranks worms, insects, fishes, serpents, tortoises, dogs, and asses as the lowest order. Elephants, horses, lions, boars, Sudras, and people not speaking Sanskrit are a step higher. The third class comprises thieves, actors, Rakshasas, and Piçāchas; the fourth athletes, dancers, armorers, drunkards, and Vaisyas; the fifth, Kshatriyas, kings, eminent soldiers and orators, the Gandharvas and

Asparasas; the sixth Brahmins, pious penitents, gods, and the great Rishis; and finally above them all is Brahmā. There is no redeemer in ancient Brahmanism; everybody must redeem himself. But sacrifice, asceticism, and philosophy sometimes succeed in reducing the number of transmigrations by leading to higher stages of existence. Most transgressions are of the nature of pollutions. Each caste is within itself a holy, distinct, and pure people, but contact with a person of a lower caste than one's own is unclean. The dead, every excretion of the body, birth, and everything connected with sexual life, are pollutions. Fortunately the cow is so holy that what from all other beings would be the most unclean of all serves the Hindoos as a purifying agent. Water and cowdung purify everything. Penitence consists in fasting for three days, or even for a month, in conjunction with various mortifications of the body or numerous recitations of prayers and portions of the Veda. In Manu's code the penalty for intoxication is dreadful; the drunkard is condemned to drink boiling rice water or boiling juice of cowdung or urine till he dies. The killing of a cow is more criminal than the murder of a person belonging to a lower caste. When a Kshatriya or Vaisya unintentionally slays a Brahman, he shall, without waiting for the sentence of the king, walk 100 *yōjana*, reciting one of the three Vedas, or build a hut in the woods, live on alms for 12 years, and carry in his girdle the skull of the slain. But if the slaying of a Brahman was intentional, then the Kshatriya shall himself demand to be shot, or hold his head three times in a fire and die. Sacrifice was still greatly practised during this period, though modern Brahmanism has for the most part abandoned all but the household sacrifices. Ancient Brahmanism distinguished four kinds of sacrifice: *havis*, *havis-yajna* or *ishtī*, oblation; *paṇu*, or *paṇu-bandha*, animal offering; *sōma* or *saumya-adhvana*, drink offering; and *pāka-yajna*, minor offerings, subsequently called *grīhya-karma*, house-offerings, consisting partly of food and partly of animals. The sacrifice of animals soon fell into disuse, and the Sūtras name the two classes of meat and animal offerings as one. These sacrifices were faithfully performed by the people, but the higher castes began to philosophize on their religion, and added to the Brāhmana scriptures the Āranyakas and Upanishads, as containing the essence or the orthodox interpretation of the entire Hindoo religion. Manu's book of laws sanctioned them. They are mainly expositions of the doctrine of the transmigration of souls. They teach that greater than all gifts to the fire of Agni is internal self-combustion, the *tapas*, glow or fire of asceticism. This is the new basis. Man is, through asceticism, meditation or philosophy, and penitence, mightier than all gods; and if he fulfils the laws prescribed for these exercises, he is immediately released from any further transmigration of

his soul, and he enters at once into Brahma. This asceticism is permitted only to the three highest castes, the twice born, *dvījas*, or Aryans. A Sudra can at best, and with the highest possible degree of self-denial, attain only to a rebirth into these fortunate castes. Legends like those of Viçvāmītra and Vasishtha, which portrayed the wonderful power which the ascetic possessed over the gods, filled the masses also with enthusiasm for the doctrine of asceticism. The great aim of the Aryan race was no longer to conquer the earth, but to subdue every natural impulse, and to be swallowed up by Brahma, as a drop is by the ocean. Though this asceticism caused an enormous waste of human life, it also gave birth to some of the greatest intellectual achievements of which man is capable.—This leads us to a new period in the history of the religion and literature of India, which is eminently one of philosophy. Ancient Hindoo philosophy, the precursor of that of Greece and Rome, was an outgrowth of that meditation which was enjoined as a means of securing a quick passage into the great Brahma. This philosophy is in its aims much loftier and in its processes much more ingenious than that of the Greeks. Indeed, in spite of the wonderful abstruseness in which it is sometimes buried, it might bear favorable comparison with the philosophies of the 18th and 19th centuries. There are especially six philosophical systems which are still considered to be orthodox, as they recognize the authority of the Vedas. They may be reduced also to three, Vedānta, Sāṅkhya, and Nyāya, each of which is represented by two forms. Vedānta signifies the aim or end of the Veda. Its legendary author is Bādarāyana or Veda-Vyāsa, who is said to be the author also of the divine Vedas themselves and of the Mahābhārata. The development of Vedantism, however, reaches into the time of modern Brahmanism. The Vedānta-Sāra, a small book which draws the ultimate conclusions of the system, is probably of a date later than the 8th century A. D. The Pūrva-Mīmāṃsā philosophy is less an independent system than a collection of addenda for the Vedas, showing how they ought to be used. There is a theistic Sāṅkhya or Yoga system by Patanjali, and an atheistic Sāṅkhya system by Kapila. The Nyāya system, by Gautama, is principally occupied with the principles of logic. Gautama lays down a syllogism of five members: Proposition, *pratījñā*, the forest is burning; reason, *hētu*, for it is smoking; example, *udāharaṇa*, whatever smokes is burning; application, *upanaya*, the forest is smoking; inference, *niḡamana*, (hence) the forest is burning. The Vaiçeshika system, by Kanāda, is an independent branch of the Nyāya philosophy. It teaches the eternity of matter in the form of atoms, and also the atomistic eternity of the soul. There is a curious dilemma in the Vedānta, which however is more clearly expressed in the Vedānta-Sāra, viz. : either Brahma

exists, and the world does not exist; or the world exists, and Brahma does not exist. Inasmuch as Brahma exists, and is in fact the only *vastu* or real existence, while all objects, especially individual souls, are only *avastu*, or unreal, it follows that the world does in reality not exist. Other philosophers preferred rather to sacrifice the unity of Brahma than abandon the idea of the reality of the world and of individual souls. Kapila's Sāṅkhya system fell into atheism, but did not therefore lose its orthodoxy with the Hindoos, as with them meditation and penitence are mightier than and superior to the gods. It says that if there were a god, he would be either limited or free, and in neither case could he be a creator. For if he were free from commotions and emotions, nothing could move him to create; and if he were limited, he himself would be subject to illusions. The Sāṅkhya explains the world as a mingling of matter and spirit, and bears in many places a strong resemblance to Aristotle's metaphysics. Its ultimate conclusion is that there is no necessity for a new birth or for trans-migrations. It seems, however, that Kapila did not relinquish the presumption of a personal immortality. He argues that in order to satisfy the longings of the human heart, there must needs be a continuing soul; and if such a soul be denied, there cannot be a highest and final destiny in store for man. The end of all Hindoo philosophy of this period is always, however, that the ascetic, whose mind is above the things of this world and fathoms the reason of the existence of all things, need not wander through other bodies, but is immediately after death absorbed by the one great soul of the world. The masses were not in a condition to find consolation in this doctrine, but had to invent some new method of salvation. The Vedic sacrifices were on the point of falling into disuse, as it had been taught that they were only effectual in proportion to their cost.—Buddha had in the mean time made his appearance, and rejected every kind of sacrifice. This had some effect also on the Hindoos who remained faithful to Brahmanism. Buddhism has a human redeemer in the person of Buddha. Brahmanism, unwilling to reject the ancient gods, but believing in the efficacy of human merits derived from prayer and meditation, seized upon the idea of having human mediators, embodiments of the gods, and ushered in a series of avatars or incarnations. Thus Krishna was worshipped in the 3d century B. C. as an Avatāra of Vishnu. The belief that the gods were bound to fulfil the will of man if expressed in sacrifice and prayer, was naturally succeeded by the belief of this age that the gods could not execute anything upon earth unless they came either in human or animal form. Vishnu, of whom the Vedas had little to say, was probably for this reason singled out of the ancient pantheon to be the divinity specially concerned in the welfare of man. He is described as having four hands,

of which one is free, while the others hold a shell, a discus, and a club. His wife is Lakshmi or Çrī, the goddess of love, grace, marriage, progeny, and wealth; the cow is her holy representative upon earth, and the lotus her symbol. About this time Siva, the Mahādēva or great god of the Dravidians, was introduced into the Brahmanical cycle of gods, by identifying him with Rudra, the god of storms. He holds a trident as the symbol of his power, a lasso or sling, an antelope, and sometimes a flame of fire in his hand. He has a third eye in the middle of his forehead, and around his neck is sometimes wound a necklace of human skulls. His wife Kālī, the black or devouring, also called Umā, Durgā, and Pārvatī, has like him three eyes, a wreath of skulls on her neck, and a club in her hand. Her face is sometimes terrific in appearance, especially on account of the long protruding teeth. Her worship is as important and general as that of Siva himself. His sons Ganēga and Kārttikeya are also objects of veneration. Sivaism as phallus worship became in time widely diffused among the Aryan as well as aboriginal races of India, and will be further discussed below, in the account of the modern forms of the Dravidian religions. Buddhism, though after 1,000 years' struggle overcome by Brahmanism, gave new directions to its doctrines. (See BUDDHISM.) Mohammedanism was less successful in leaving its mark upon it. The doctrine of the incarnation of the gods in human beings and animals now became a prominent feature of the Hindoo religion. It seems that the incarnation of Vishnu as Krishna was taught in opposition to Buddha. An attempt was even made to represent Buddha himself as an incarnation of the same god. Through the endeavor to unite and reconcile all the religious elements inimical to Buddhism, a Trimūrti was invented, or a trinity composed of the great gods Brahmā, Vishnu, and Siva. A new religious literature sprang up in the Purānas, which were not like the Vedas removed from the people as too holy, but were written specially for them. Their contents are mythological, but they served as polemics against Buddhism, and even of one Brahmanical sect against another. There is thus no unity in modern Brahmanism. It has no hierarchy that embraces the entire Hindoo population. In the holy city Benares, for example, worship side by side a number of sects whose doctrines are more or less at variance with each other. Denominations is perhaps a better name than sects for these divisions, as they are not mere deviations from the main Brahman religion, but distinct separations from it. The main divisions are Vishnuites and Sivaites, the former exalting Vishnu, the latter Siva, above Brahmā. Each division has again several divisions within itself, probably caused by influential expounders of the doctrines. These various distinctions of denominations or sects produced a number of subdivisions in the caste of

Brahmans. The other castes were also multiplied. Sects which reject the system of castes, as the Lingaites of Mahratta, constitute each a caste of their own. The gods also have enormously increased in numbers, and they are said to be as many as 330 millions, since it seemed but just that the heavens should be as largely peopled as the earth. The Vedānta philosophy attained the most influential position among the Hindoo systems, and effected a union with Sivaism, while the Vishnuites embraced the deistic Sāṅkhya. The most renowned philosopher was Çankarāchārya, who lived in the 8th century. He was a Brahman of the Namburi tribe, then dominant in Travancore. He recognized, instead of the original four, 72 castes, and founded numerous convents, disputed considerably with the Jains and Vishnuites, and is said to have died in the Himalaya at the age of 32. He revived the Vedānta philosophy, applied it against Buddhism, and wrote among others the Bhāshyas, which are commentaries on the Vedas, but more directly on the Sūtras. The Vishnuites number among their celebrated philosophers Rāmānuja of the 12th, and Madhvāchārya of the 14th century; but their fame is not equal to that of Çankarāchārya. The Vishnuite Vallabhāchārya founded in the 16th century the voluptuous Krishna-shepherd worship, which places Krishna over Vishnu himself. Another enthusiastic Krishna worship was instituted about the same time by Chaitanya in Bengal. In the 12th century arose in the Mahratta country a new form of Sivaism. Basava, its founder, formed monkish brotherhoods in imitation of Buddhism, but he was a bitter enemy to the Buddhists, as represented by the Jains. This sect is the Jangama Lingaism, which uses the Canarese language as its sacred tongue. The Çākta denomination gives adoration not to any of the three great gods themselves, but only to their wives, and especially to the spouse of Siva, and is very sensual in worship. Remnants of the ancient Sudra religion are still to be found in Bengal, and they bear a strong resemblance to the magic worship of savage tribes. Islamism made considerable progress in the mean time, and in 1871 a third of the population of Bengal were Mohammedans. A mixture of Hindooism and Islamism is represented by the religion of the Sikhs, and another of Buddhism and Brahmanism by that of the Jains.—The most important modern religious works known to Europeans are the following. After the Purānas appeared 18 Upapurānas of similar contents. Each temple of importance has its own local Purāna, narrating the story of the god and his manifestations in that place, and often containing items of valuable historic information. The Tantras are productions in which Siva is represented as conversing with Durgā; they are the magic books of the Çaktas. The most important work written in Tamil is Tiruvalluvar's Kural, a collection of sayings of a purely ethical character. The Basava Purānas of the

sect of Lingaites are valuable works for the history of Hindoo sects.—Prominent among the recent developments of the Brahmanical religion stands the idea of the trinity. It was formerly supposed by European scholars that the Trimūrti, or trinity of Brahmā, Vishnu, and Siva, was a primitive doctrine and the basis of the Indian religion; but it is evidently quite a modern conception. This trinity is represented by an image of a body with three heads cut out of a single block of stone. Theoretically, Brahmā is the creator, Vishnu the preserver, and Siva the destroyer; but no cult assigns either temple or feast to the Trimūrti, and it would be greatly unlike the popular conception of Siva to consider him a god of destruction. It would be better, however, to examine first the place which Vishnu occupies in the popular mind. Vishnu pushed Indra back into oblivion. Ten avatars are commonly assigned to him, and they follow each other in an increasing scale of perfection. The first three are incarnations of animals: fish, tortoise, and boar. The fourth is the Manu lion. The human avatars begin with the fifth: first a dwarf, then a hero, and then the still more exalted persons of a Rāmachandra and a Krishna. It is usual to name also an incarnation of Buddha as a concession to Buddhism, but several writings name other forms in which Vishnu appeared, and expect the god finally to come himself. The revelation of the future advent of Vishnu predicts that at a time when the highest age of man will be only 23 years, a portion of the eternal godhead will be born in the village Sambhala to the Brahman family of Vishnuyāça. He shall be called Kalki, and possess eight superhuman powers. He shall destroy all Mlēchas, Dasyus, and unjust persons, and shall restore righteousness upon earth. The spirits of those who are still alive at the end of the Kali-yuga life shall be changed into forms transparent as crystal, and shall produce a race willing to obey the laws of Krita-yuga, who shall be the fathers of a new humanity. Krita-yuga shall come again when sun and moon have disappeared in the moon house Tishya, near the planet Brihaspati or Jupiter. This will occur at the end of 360,000 human years or 1,200 years of the gods, counting from the death of Krishna. The person of Siva was too lofty and powerful to be satisfied like Vishnu to appear as a being of this world. As Vishnu could not, however, be allowed to be considered the only one capable of avatars, it was taught that Siva also occasionally dwelt among men, but only as the incorporation of some attribute of himself. When Nārade, the messenger of the gods, reported to Siva that his worship was falling off upon earth, Siva sent only Nandikēçvara, the bull upon which he rides. The Lingaites also have in their Purānas legends of such descents of divine attributes and symbols among them. One of them gives a most wondrous origin to their teacher Basava. The Yōgins or Gosain, com-

monly known as Fakirs, are worshippers of Siva. Modern Brahmanism has also a female trinity, composed of the wives of Brahmá, Vishnu, and Siva. Sarasvatî, Brahmá's wife, is the only goddess of arts, of which language is one, and she is said to punish liars, but not very heavily. Lakshmi, the wife of Vishnu, is the giver of temporal happiness; it is through her that mortals obtain wives, children, dwellings, friends, harvests, wealth, health, and strength. Párvatî, the wife of Siva, who is the most generally worshipped of the three, has the same attributes as Lakshmi in the Sivaitic Purânas; but in Bengal and in southern India she is, under the name of Kâli, a bloodthirsty goddess, and her images depict her as truly horrid. She is the goddess of cholera and all other epidemics. She can be appeased only with bloody sacrifice, and even human beings are offered up to her wherever the English authorities do not interfere. In the south Brahman mythology represents the aboriginal *grâma-dêvatâs* to be a ninefold development of Párvatî, or rather of the universal productive energy of the deity. The Çakti worship is, like Lingaism, based on sexual relations. The former has chosen the female principle, the lap of the mother of nature, instead of the male, which receives the veneration of the latter. The various sects belonging to it rival each other in obscenity and voluptuousness.—Among the other gods of modern Brahmanism, Ganêça and Kârttikêya, the sons of Siva, are also prominent. The former is the god of wisdom and cunning, on whom it is well to call before undertaking anything. He has the head of an elephant, and his image is found everywhere, even in temples not dedicated to him, by the wayside, and in many private houses. The Gânapatyas are a sect who make him an object of special worship. Kârttikêya or Skanda, called Subrahmanya and Shanmukha in the Deccan, is the six-headed god of war, whose office is to subdue the demon Sûra or Târaka, and who by doing penance for 2,000 years obtained the power of governing the whole world without being put to death either by Siva or by any other god. Six nymphs quarrelled for the privilege of nursing him when he was born on the river Ganges, and in order not to vex any of these Krittikâs he took six heads and fed on them all. His feast in the month of Kârttika or October is principally attended by music, and fires are lit upon the hills as a token of the return of the victorious warriors. Daksha also is important. He is one of the ancient Adityas, and the Vishnu Purâna tells a wondrous story of how he came to be in the train of the Mahâdêva Siva. Gangâ, the celebrated goddess of the river, is a lovely person with a lotus flower in her hand. Bathing in the Ganges cleanses from all sins, and whoever dies in the river is at once dissolved in the great Brahma. Near the source, at the junction of the Jumna near Allahabad, near Benares, and at the mouth of the river,

her powers are especially effective on account of certain legends connected with these places. Among the eight Lôkapâlas or guardians of the world enumerated above, Yama now employs messengers, Yamadûtas, whose duty it is to pull the souls out of corpses and lead them to him bound with ropes. But when people have been very pious Yama himself calls for their souls. The messengers are depicted as deformed, clad in skins of wild animals, and as having eyes of fire and long hair and teeth. When they have brought a soul before the judge of the dead, the first clerk Chandragupta is commanded to read the list of the good and evil deeds of the deceased which is contained in the book Ugrasandhâni. Then sentence is passed whether the soul shall be placed in hell, or reinhabit an earthly form, or rise to a higher sphere. Kuvêra is lord of the treasures hid in the earth, and he resides in the mines of Kailâsa, where his dwarfish, ugly servants keep watch, and can be induced by magic charms to reveal where treasures are concealed. Kuvêra himself is a frightful human form, with three heads, three legs, eight teeth, a single ring through the ears, green eyes, and white sores on his body. Kâma or Manmatha rides on a parrot, and wounds with his arrow those who love. He belongs to the family of Vishnu. The fire of Siva's eye reduced him to ashes, and he will not be born again before Siva marries Párvatî, and then he will be a son of Krishna. His companion is the beautiful Rati, whom he captured from the house of the giant Sambara. In comparison with the dissolute worship of Çakti, the worship of the elevated and poetic side of human love as represented by Kâma is quite insignificant.—The distinctions of caste are rapidly disappearing. The Kshatriyas and Vaisyas long since lost their separate existence, and many of the occupations originally exclusively theirs are now followed also by the Brahmans. Though the superior castes may engage in the pursuits properly belonging to the lower, the latter are not permitted to usurp the functions of the former. Brahmans now hold government offices, act as soldiers, and enter the services of Europeans and Mohammedans, and even of the Sudras. But whatever their position, they try not to transgress the rules and observances anciently prescribed for them. They avoid, for example, trafficking with certain commodities, such as leather, contact with which is considered polluting; they do not eat or touch certain kinds of food, nor eat with or in the immediate presence of one of an inferior caste. There are classes so degraded that their mere shadow falling on a man of higher caste causes pollution. In Malabar when under native rule it was not uncommon for a man of high caste to strike dead on the spot a man of low caste for having touched him, even if accidentally; the act was regarded as justifiable homicide, and was not punished by the authorities. The condition of the lowest castes un-

der native rule was one of the most abject subjection, and so debased were they considered, both socially and spiritually, that it was a crime for a Brahman to read the sacred writings in their presence, or to give them any religious counsel or instruction whatever. Beneath the Sudras there was a numerous class of outcasts and their descendants, who, by forfeiting their standing in their respective castes and becoming polluted, had sunk to the lowest pitch of social degradation, and were regarded as utterly vile. A loss of caste involved a forfeiture of all civil rights and of all property. The British government, however, has prohibited the enforcement of any forfeiture or disinheritance by reason of the renunciation or deprivation of caste; the law has been steadily enforced, and has had an important and salutary effect upon the social state of India.—The Brahmans are now undergoing a religious crisis. The sect of Kâlajñanis, whose sacred book is the Kâlajñana, "Knowledge of the Age," written about 1780, believe that the god of gods himself will descend to earth and raise the dead. The Nudis in South Mahratta entertain a similar belief, but both sects seem to be dying out. There is one sect, however, the Brahmô-Sâmâj, which is steadily increasing in number, and which has attracted considerable attention. Its doctrines are not properly a mixture of Brahmanism and Christianity, but rather a rationalistic development of both. The sect is said to have been founded in 1830 by Ram Mohun Roy. The first converts were pupils of Christian educational institutions. They were joined by Mohammedans and by other Brahmans, and formed together a church whose principal doctrines are the adoration of one God, the loving father of all, and brotherly love toward all men. Their great purpose is to do away with distinctions of caste and religion. The head of the sect is now Babu Keshab Chander Sen, and under his energetic guidance it has been established in all the larger cities of India. It was hoped that they would eventually adopt the fundamental doctrines of Christianity, but at a meeting held in 1866 in Calcutta, Jesus was declared to be a divine incarnation in no higher degree than every distinguished person might be said to be such. Excepting the wonderful mystical word *ôm*, only such portions of the Vedas and the Bible as are merely theistic and not miraculous are admitted into their canon.—The principal recent authorities on the religion and literature of India are: Max Müller, "History of Ancient Sanskrit Literature" (London, 1859); Muir, "Original Sanskrit Texts on the Origin and History of the People of India" (vols. i.-v., London, 1863-'70); Lassen, *Indische Alterthumskunde* (2d ed., 2 vols., Leipsic, 1867-'73); Whitney, "Oriental and Linguistic Studies" (New York, 1872); Duncker, *Geschichte des Alterthums* (vol. i., 4th ed., Leipsic, 1874); and Wurm, *Geschichte der indischen Religion* (Basel, 1874).

INDIANA, one of the interior states of the American Union, and the sixth admitted under the federal constitution, situated between lat. 37° 47' and 41° 46' N., and lon. 84° 49' and 88° 2' W.; extreme length N. and S. 276 m., average breadth 140 m.; area, 33,809 sq. m., or

State Seal of Indiana.

21,637,760 acres. It is bounded N. by Lake Michigan and the state of Michigan, E. by Ohio, S. by Kentucky, from which it is separated by the Ohio river, and W. by Illinois, from which it is partly separated by the Wabash. It is divided into 92 counties, viz.: Adams, Allen, Bartholomew, Benton, Blackford, Boone, Brown, Carroll, Cass, Clark, Clay, Clinton, Crawford, Daviess, Dearborn, Decatur, De Kalb, Delaware, Dubois, Elkhart, Fayette, Floyd, Fountain, Franklin, Fulton, Gibson, Grant, Greene, Hamilton, Hancock, Harrison, Hendricks, Henry, Howard, Huntington, Jackson, Jasper, Jay, Jefferson, Jennings, Johnson, Knox, Kosciusko, La Grange, Lake, La Porte, Lawrence, Madison, Marion, Marshall, Martin, Miami, Monroe, Montgomery, Morgan, Newton, Noble, Ohio, Orange, Owen, Parke, Perry, Pike, Porter, Posey, Pulaski, Putnam, Randolph, Ripley, Rush, St. Joseph, Scott, Shelby, Spencer, Starke, Steuben, Sullivan, Switzerland, Tippecanoe, Tipton, Union, Vanderburgh, Vermilion, Vigo, Wabash, Warren, Warrick, Washington, Wayne, Wells, White, Whitely. Indianapolis, the capital, is near the centre of the state. In 1874 there were 27 cities in Indiana: Columbia, with 1,663 inhabitants in 1870; Connersville, 2,496; Evansville, 21,830; Fort Wayne, 17,718; Franklin City, 2,707; Goshen, 3,133; Greencastle, 3,227; Kendallville, 2,164; Indianapolis, 48,244; Jeffersonville, 7,254; Lafayette, 13,506; La Porte, 6,581; Lawrenceburg, 3,159; Logansport, 8,950; Madison, 10,709; Mount Vernon, 2,880; New Albany, 15,396; Peru, 3,617; Richmond, 9,445; Rising Sun, 1,760; Seymour, 2,372; Shelbyville, 2,731; South Bend, 7,206; Terre Haute, 16,103; Valparaiso, 2,765; Vincennes, 5,440; and Wabash City, 2,881. Michigan City is the only lake port of the state. The

population in 1800 and at subsequent decennial periods was as follows:

CENSUS YEARS.	White.	Free Colored.	Slaves.	Total.	Rank.
1800	5,343	163	135	5,641	20
1810	23,890	398	237	24,520	21
1820	145,758	1,230	190	147,178	18
1830	339,399	3,629	3	343,031	13
1840	678,698	7,165	3	685,866	10
1850	977,154	11,262	..	*988,416	7
1860	1,338,710	11,428	..	1,350,428	6
1870	1,655,837	24,560	..	1,680,637	6

Of the total population in 1870, 857,994 were males and 822,643 females; 1,539,163 were of native and 141,474 of foreign birth; and there were 240 Indians. Of the native-born, 1,048,575 were born in the state, 16,598 in Illinois, 3,483 in Iowa, 76,524 in Kentucky, 3,490 in Massachusetts, 5,693 in Michigan, 6,682 in New Jersey, 29,518 in New York, 24,799 in North Carolina, 189,359 in Ohio, 57,291 in Pennsylvania, 12,276 in Tennessee, and 32,489 in Virginia and West Virginia. Of the foreigners, 4,765 were born in British America, 6,363 in France, 78,060 in Germany, 9,945 in England, 28,698 in Ireland, 2,507 in Scotland, 556 in Wales, 873 in Holland, 2,180 in Sweden, and 4,287 in Switzerland. The density of population was 49·71 persons to a square mile. The state contained 320,160 families, with an average of 5·25 persons each, and 318,469 dwellings, with an average of 5·28 persons each. The increase of population from 1860 to 1870 was 24·45 per cent. The number of male citizens 21 years old and upward was 376,780. There were in the state 567,175 persons from 5 to 18 years of age; the total number of persons attending school was 395,263; 76,634 persons 10 years of age and over were unable to read, and 127,124 could not write. Of the latter, 113,185 were of native and 13,939 of foreign birth; 53,359 were males and 73,765 females; 118,761 were white and 8,258 colored; 11,072 were from 10 to 15 years old, 15,630 from 15 to 21, and 100,422 were 21 and over, of whom 36,331 were white males, 57,651 white females, 3,182 colored males, 3,181 colored females, and 77 Indians. The percentage of illiterates 10 years of age and over to the total population of the same age was 10·61, being 8·71 for males and 12·61 for females. The percentage of illiteracy among male adults was 10·09; females, 16·77. The number of paupers supported during the year ending June 1, 1870, was 4,657, at a cost of \$403,521. On June 1, 1870, 3,652 were receiving support, of whom 2,790 were natives, including 2,583 white and 207 colored, and 862 foreigners. There were 1,374 criminals committed during the year. Of the total number (907) in prison June 1, 1870, 755 were of native and 152 of foreign birth; of the natives, 691 were white and 64 colored. The state contained 991 blind, 872 deaf and dumb, 1,504 insane, and 1,360 idiotic. Of the total population 10

years of age and over (1,197,936), there were engaged in all occupations 459,369 persons; in agriculture, 266,777, including 83,949 laborers, and 181,895 farmers and planters; in professional and personal services, 80,018, of whom 1,787 were clergymen, 22,542 domestic servants, 34,954 laborers not specified, 1,685 lawyers, 3,613 physicians and surgeons, and 5,018 teachers not specified; in trade and transportation, 36,517; and in manufactures and mechanical and mining industries, 76,057. The number of deaths from all causes was 17,661; from consumption, 2,807, being 1 death from consumption to 6·3 from all causes; from pneumonia, 1,514, being 1 from that disease to 11·7 from all causes; from diphtheria and scarlet fever, 594; from intermittent and remittent fevers, 521; from enteric fever, 1,029; from diarrhœa, dysentery, and enteritis, 1,241.—Indiana is entirely wanting in mountains, and at least two thirds of the surface is level or undulating. It has consequently no watershed, but there are continuous slopes of great extent, and the difference of elevation between the highest land and the Ohio river at the falls is nearly 600 ft., and a considerable difference (about 70 ft.) is observed between the level of the Ohio at the falls and at the mouth of the Wabash. The river hills extend at various distances from and parallel to the course of the Ohio and other streams, and enclose bottom lands which are chiefly rich alluvions and thickly wooded. These hills along the Ohio are generally as high as the highest levels of the interior, often of a rugged and broken aspect, and where cut through by tributaries of the Ohio present much imposing scenery. Behind these a table land spreads out and forms the interior, and here every feature is changed; instead of the bottoms, with their forests, the most varied landscape appears—here groves of oak, ash, and other trees, there vast level prairies; and again the surface is undulating, and occasionally rises into hills from 100 to 300 ft. high. For topographical description, however, the state may be divided into the valleys of its rivers. The Ohio valley, including that of the Whitewater, contains about 5,500 sq. m.; this is a limestone region, and was originally clothed with heavy forests. The hills are abrupt and broken, and numerous tributaries of the Ohio break through them. Of this division of the state about two thirds is good farming land, and the residue either too hilly or too sterile for profitable cultivation. White River valley extends from the Wabash centrally through the state to the Ohio line, and covers about 9,000 sq. m. It is almost uniformly level, and heavily timbered, except in the W. parts, where there are large prairies and barrens and ranges of low rugged hills. Limestone beds exist on White river and between its two forks, and are abundant and excellent along the lower part of the river. The soils are of the richest description. Most of the streams are clear and never-failing,

and water power is abundant. The Wabash valley is the largest division, and embraces upward of 12,000 sq. m. It interlocks with that of White river, and the E. portion resembles it. It is equally fertile, but less broken. The middle part of the valley has extensive water power. From the river hills of the Ohio to the Wabash the surface is an inclined plane. The valley of the Maumee occupies about 2,000 sq. m. in the N. E., and carries its waters to Lake Erie. The N. and N. W. part of the state, drained by the St. Joseph's, which flows into Lake Michigan, and the Kankakee, a constituent of the Illinois, in its general character is level, mostly prairie; in parts it is sandy, and along the Kankakee swampy. Near Lake Michigan the country has extensive sand hills, which are covered only with stunted and shrivelled pines and burr oaks; but a few miles back from the lake shore a rich agricultural country is found.—The Ohio, the final recipient of the principal streams, borders the state on the south from the Miami to the Wabash, a distance by the river's course of 380 m. Laughery, Indian Kentucky, Silver, Indian Blue, Anderson, Big Pigeon, Little Pigeon, &c., are its principal tributaries from Indiana, but none of them are navigable. The Whitewater joins the Miami 6 m. above its entrance into the Ohio. The Wabash has its head waters in Ohio; at first its course is N. W. to the middle of Huntington co., thence W. S. W. to Williamsport in Warren co., and the remainder of its course S. to the Ohio. Its length is about 550 m., and it has been navigated about 300 m. by steamboats. Its principal affluents are, from the south and east, the Salamonie, Mississinewa, Wildcat, Sugar or Rock, Raccoon, and Patoka rivers; and from the north and west, Little Wabash and Embarras in Illinois, the Vermilion in both states, and in Indiana Tippecanoe, Eel, and Little rivers. White river, the most important of these, falls into the Wabash 100 m. above its mouth; the West fork, its longest branch, rises near the Ohio line, not far from the S. sources of the Wabash and W. constituents of the Miami, and runs in a S. W. direction, receiving in its course Eel river, Fall creek, &c.; and the East fork, the principal feeders of which are Salt, Muscatuck, Sand, Clifty, Flat Rock, Sugar, and other streams, rises in the S. E. part of the state, and has a W. course to its union with the West fork, the two forming White river proper, 50 m. above its entrance into the Wabash. The St. Joseph's and St. Mary's form the Maumee, which passes into Ohio and to Lake Erie. Another St. Joseph's, with its tributaries the Elkhart, &c., passes into Lake Michigan. The Kankakee, a principal constituent of the Illinois, runs sluggishly through the N. W. counties for 100 m.; extensive marshes everywhere bound its course. The Iroquois or Pickamink rises S. of the Kankakee, runs nearly parallel to it for 50 m., and joins it in Illinois. Deep and Calumet rivers

lie near to and S. of Lake Michigan, and in some places are only separated from it by banks of sand. Numerous lakes and ponds are found, principally N. of the Wabash. Several of them have no outlets; they are generally clear, and have sandy shores and bottoms. They seldom exceed a few acres in extent, though several at the head of Tippecanoe river and Turtle creek, and near the city of La Porte, cover a considerable area. The largest, Beaver lake, near the Illinois line in Jasper co., had a surface of 10,000 acres, and on the south was bordered by an extensive marsh; but most of the land has been reclaimed, and the lake itself nearly drained.—The geological survey of Indiana has been several years in progress under the direction of the state geologist, Prof. E. T. Cox, assisted by Professors John Collett, B. C. Hobbs, R. B. Warder, and Dr. G. M. Levette. The third and fourth annual reports, for the years 1871 and 1872, were published in one volume in 1872. The most valuable mineral found in Indiana is coal, which exists here in great abundance, and forms part of the great coal field which extends through Illinois, Indiana, and Kentucky. The following statement by Prof. Cox shows the extent and character of this important source of wealth: "The measures cover an area of about 6,500 sq. m., in the S. W. part of the state, and extend from Warren co. on the north to the Ohio river on the south, a distance of about 150 m. The following counties lie within its area: Warren, Fountain, Parke, Vermilion, Vigo, Clay, Sullivan, Greene, Knox, Daviess, Martin, Gibson, Pike, Dubois, Vanderburg, Warrick, Spencer, Perry, and a small part of Crawford, Monroe, Putnam, and Montgomery. The coal is all bituminous, but is divisible into three well marked varieties: caking coal, non-caking or block coal, and cannel coal. The total depth of the measures is from 600 to 800 ft., with 12 to 14 distinct seams of coal, though they are not all present throughout the entire area of the field. The seams range from 1 ft. to 11 ft. in thickness, and the field may, from the character of the coal, be divided from north to south into two zones; the western contains the seams of caking coal, and the eastern the non-caking or block coal. There are from three to four workable seams of caking coal, ranging from 3½ to 11 ft. in thickness. At most of the localities where these are being worked, the coal is mined by adits driven in on the face of the ridges, and the deepest shafts in the state are less than 300 ft., the average depth to win the coal being not over 75 ft. The eastern zone of the coal measures has an area of more than 450 sq. m. It is here that we find the celebrated block coal, a fossil fuel which is used in the raw state for making pig iron. In fact this coal, from its physical structure and freedom from impurities, is peculiarly suited to metallurgical purposes. It is likewise valuable for generating steam and for household uses.

There are as many as eight distinct seams of block coal in this zone, three of which are workable, having an average thickness of 4 ft. In some places this coal is mined by adits, but generally from shafts, 40 to 80 ft. deep. The seams are crossed by cleavage lines, and the coal is usually mined without powder, and may be taken out in blocks weighing a ton or more." In 1871 there were 24 block coal mines in operation, and about 1,500 tons were mined daily; in 1873 the number of mines had increased to upward of 50, and the daily production to about 5,000 tons. In 1873 eight blast furnaces in Indiana were using the block coal for smelting ores. The quality of the coal, its vicinity to available iron ore beds, together with convenient railroad facilities, give to Indiana marked advantages for the manufacture of iron and steel. (For an analysis of the coal of Indiana, see COAL.) A seam of superior cannel coal is worked in Daviess co.; the vein is 5 ft. thick, the upper 3½ ft. being cannel coal and the remainder a beautiful jet-black caking coal. Peat or turf exists in considerable quantities in the northern part of the state, but, owing to the abundance of wood, is not much used. There are numerous deposits of bog iron ore in the northern part of the state, and clay ironstones and impure carbonates and brown oxides are scattered over the counties embraced in the coal measures. In some places the beds are quite thick, and, though inferior to the rich pure ores of Missouri, will prove valuable for mixing with the latter and aid in making special grades of iron. Indiana possesses some of the finest quarries of building stone in the west; they include both limestone and sandstone. Gannister rock, used for furnace hearths and for lining Bessemer converters, and fire clays, are also found in great abundance. Salt springs exist on the eastern border of the coal formation. Perhaps the most remarkable natural curiosity in Indiana is the Wyandotte cave, 4 m. from Leavenworth, Crawford co., in the southern part of the state, which in many respects rivals the famous Mammoth cave of Kentucky. (See WYANDOTTE CAVE.)—The climate, like that of all the states W. of the Ohio, is liable to frequent and sudden changes. The prevailing winds in winter are from the north and northwest, and in other seasons from the south and southwest, and from the general evenness of the country have a free passage and are in constant motion. The heats of summer are thus modified; but in winter the cold is extreme, though less so than in Illinois. The mean temperature of the year is 52°; that of winter 31°, of spring 51°, of summer 76°, and of autumn 55°. This is nearly the climate of Bordeaux, France, 5° further N. than Indianapolis and on the seaboard. The rainfall is about 38 in. in the year, viz.: 4·97 in winter, 7·79 in spring, 16·92 in summer, and 7·87 in autumn. The earlier fruits blossom in March.—The soil is generally good, and much of it remarkably fer-

tile. The richest lands are found along the Wabash, White, and Whitewater rivers. Few states have so little unavailable land; even its wet and marshy lands are brought under successful cultivation. About one eighth part of the state is prairie land, and about one third is covered with a fine forest. The forests contain all the trees natural to the climate of the middle zone of the Union, but oak and beech preponderate; next in order are the sugar maple, hickory, ash, black walnut, poplar, elm, sycamore, &c.; and the principal undergrowths are dogwood, pawpaw, plum, thorn, persimmon, and crabapple. In most parts oak and beech mast is found in such quantities as to contribute largely to feeding and fattening hogs.—Indiana ranks high as an agricultural state; in the production of wheat in 1870 it ranked next to Illinois and Iowa, and in Indian corn next to Illinois, Iowa, Ohio, and Missouri. The chief farm productions and live stock, as reported by the federal census in 1870 and the state authorities in 1873, were as follows:

PRODUCTIONS.	1870.	1873.
Wheat, bushels.....	27,747,222	22,149,527
Indian corn.....	51,094,538	51,155,485

Sheep.....	1,612,680	1,235,874
Swine.....	1,872,230	2,999,139
Cattle.....	1,211,246

The returns of live stock for 1870 include only animals on farms, while in 1873 the entire number in the state is returned. According to the census of 1870, there were in the state 10,104,279 acres of improved land, 7,189,334 of woodland, and 826,035 of other unimproved land. The total number of farms was 161,289, including 55,614 containing 20 and under 50 acres; 52,614, 50 and under 100; 29,433, 100 and under

500; 1,004, 500 and under 1,000; and 76, 1,000 and over. The cash value of farms was \$634,804,189; of farming implements and machinery, \$17,676,591; wages paid during the year, including value of board, \$9,675,348; total estimated value of all farm productions, including betterments and additions to stock, \$122,914,302; value of orchard products, \$2,858,086; of produce of market gardens, \$486,477; of forest products, \$2,645,679; of home manufactures, \$605,639; of animals slaughtered and sold for slaughter, \$30,246,962; of all live stock, \$83,776,762. In 1873 there were 6,162,157 acres in cultivation, of which 1,902,599 were devoted to wheat, 2,627,980 to Indian corn, 624,795 to oats, 985,529 to meadow, and 4,511,775 to pasture and woodland. The value of slaughtered animals was \$3,938,754. There were 570,382 tons of coal mined, and 1,167,661 bushels of lime made.—Indiana has no

direct foreign commerce, but it has a vast domestic and inter-state trade by means of its navigable waters and magnificent systems of railroads and canals. Its geographical position is such that the whole land commerce between the manufacturing states of the east and the country west of the Mississippi must pass through its territory. Evansville is a United States port of delivery. In 1873 there were enrolled here 75 vessels with an aggregate tonnage of 11,474. In 1845 there were 30 m. of railroad in Indiana; in 1855, 1,406; in 1865, 2,217; in 1870, 3,177; and in 1873, 3,544. Of the 92 counties of the state, all but five were in the last mentioned year traversed by railroads. The following table exhibits the railroads of the state in 1873, with their termini; also the assessed value, including main and side track and rolling stock, as reported by the state board of equalization:

CORPORATIONS.	TERMINI.	Miles completed in the state in 1873.	Miles between termini when different from preceding.	Total assessment.
Cincinnati, Hamilton, and Indianapolis.....	Hamilton, O., and Indianapolis.....	77	98	\$551,226

The Wabash and Erie canal, the longest in the United States, connecting the Maumee river at Toledo with Evansville on the Ohio, 467 m., has 374 m. of its course in Indiana, and passes through Fort Wayne, Huntington, Wabash, Peru, Logansport, Delphi, Lafayette, Attica, Covington, Montezuma, Terre Haute, Bloomfield,

and Petersburg. The Whitewater canal extends from Lawrenceburg on the Ohio to Hagerstown, 75 m., and takes in its course Brooksville, Connersville, and Cambridge. These canals are little used now. In 1873 the state contained 6,943 miles of telegraph, the assessed value of which was \$807,874. There

were 125 foreign insurance companies doing business in the state; their gross receipts for the six months ending July 1, 1873, amounted to \$1,169,413; losses paid, \$608,950; tax paid, \$17,498. There were 92 national banks, with an aggregate paid-in capital of \$17,611,800, and an outstanding circulation of \$14,536,015. The bank circulation of the state was \$14,706,415, being \$8 75 per capita and 1-2 per cent. of the wealth of the state; ratio of circulation to capital, 81.9. The total number

of manufacturing establishments in 1870 was 11,847, using 2,881 steam engines of 76,851 horse power and 1,090 water wheels of 23,518 horse power, and employing 58,852 hands, of whom 54,412 were males above 16 years of age, 2,272 females above 15, and 2,168 youths. The capital invested amounted to \$52,052,425; wages paid during the year, \$18,366,780; value of materials consumed, \$63,135,492; of products, \$108,617,278. The chief industries are exhibited in the following table:

INDUSTRIES.	No. of establishments.	Steam engines, horse power.	Water wheels, horse power.	Hands employed.	Capital.	Wages.	Materials.	Products.

—The constitution of Indiana is dated Feb. 10, 1851, and superseded that of June 29, 1816. Every male citizen 21 years of age, and who has resided in the state six months, possesses the right of voting. The general assembly consists of a senate of 50 members elected for four years, one half every second year, and a house of representatives of 100 members elected for two years. The legislative sessions are biennial, beginning on the Thursday after the first Monday of January in odd years. Members of the legislature receive \$8 a day during the session. The governor and lieutenant governor are elected for four years; the former has a salary of \$8,000 a year. The other chief state officers are the secretary of state, salary \$2,000; auditor, \$2,500; treasurer, \$3,000; attorney general, \$3,000; and superintendent of public instruction, \$2,000. These officials are elected for a term of two years. A majority vote of each house is sufficient to pass a bill over the veto of the executive. The state election is held on the second Tuesday of October in even years. The judicial power is vested in a supreme, a circuit, and a superior court. The supreme court consists of five judges, who are elected by the people for a term of six years, and receive an annual salary of \$4,000 each. The state is divided into five supreme judicial districts and 38 circuit districts. Each of the 38 circuit judges receives

an annual salary of \$2,500; they are elected by the people for a term of six years. A superior court of three judges elected for four years may be established in any county containing a city of 40,000 inhabitants; the only one yet established is in Marion co., of which Indianapolis is the chief city. Special criminal circuit courts are provided for seven counties of the state: Allen, Floyd, Clark, Marion, Tippecanoe, Vanderburgh, and Vigo. The officers elected by the people in each county are, a clerk of circuit court, auditor, recorder, treasurer, sheriff, coroner, and surveyor—the first three for four years, and the others for two years. Justices of the peace are elected in each township for four years. Indiana is represented in congress by two senators and 13 representatives, and has therefore 15 votes in the electoral college. The system of granting divorces in Indiana, which had attracted wide attention on account of its elasticity, was amended in 1873 and made somewhat more stringent. The causes of divorce under the new law are: 1, adultery, except in certain specified cases; 2, impotency existing at the time of the marriage; 3, abandonment for two years; 4, cruel and inhuman treatment of either party by the other; 5, habitual drunkenness of either party, or the failure of the husband to make reasonable provision for the family; 6, the failure of the husband to make reasonable provision for his fam-

ily for a period of two years; 7, the conviction of either party subsequent to the marriage, in any country, of an infamous crime. Divorces may be decreed by the circuit or superior court on petition of a person who is and has been a *bona fide* resident of the state for the preceding two years, and of the county for at least six months; such residence to be proved by the oath of the petitioner and the testimony of at least two witnesses who are resident freeholders and householders of the state. Murder, treason, and killing in a duel are capital offences, punishable with death. Marriage between negroes and white persons is declared a misdemeanor, the penalty of which is imprisonment from one to ten years. By act of 1873 women are declared eligible to any office the election or appointment to which is vested in the general assembly or the governor. The state debt on Nov. 1, 1873, was \$4,898,657, including \$3,904,733 domestic and \$994,030 foreign debt. The receipts into the state treasury during the preceding year were \$2,875,449, and the disbursements, including several extraordinary items, \$3,445,298. Of the receipts, \$438,191 were from state revenue, \$1,372,993 from the common school fund, \$190,603 from public institutions, and \$1,524,545 from miscellaneous sources. The most important items of expenditure were \$1,361,341 for common schools, \$1,193,442 on account of public debt, \$352,576 for benevolent institutions, \$296,180 for reformatory institutions, \$289,934 for ordinary expenses, and \$278,373 for legislative expenses. The state tax was 15 cents on the \$100 for general purposes, and 16 cents for schools. The total valuation of real and personal property was \$279,032,209 in 1856, \$578,484,109 in 1866, \$662,283,178 in 1870, and \$950,467,854 in 1873, the last including personal property to the extent of \$247,146,331.—The public institutions supported entirely or in part by the state are the hospital for the insane, the institution for the deaf and dumb, and the institution for the blind in Indianapolis, house of refuge at Plainfield, soldiers' home at Knightstown, northern state prison at Michigan City, southern state prison at Jeffersonville, reformatory institution for women and girls in Indianapolis, normal school in Terre Haute, state university at Bloomington, and agricultural college at Lafayette. The state hospital for the insane, which was opened in 1848, had 474 inmates at the close of 1873; during the year 320 were admitted and 314 discharged. The current expenditures for the year amounted to \$155,470. The institution for educating the deaf and dumb is open to all persons of that class in the state between the ages of 10 and 21 years, free of charge for board and tuition. It is not an asylum, but an educational institution, and comprises a manual labor department. In 1873 there were 14 instructors and 331 pupils; the total disbursements on account of the institution amounted to \$73,632. The institute for the education of

the blind is also strictly educational, and is designed for the benefit of those between 9 and 21 years of age. At the close of 1873, 106 pupils were receiving instruction from 11 teachers; the resources of the institute during the year amounted to \$42,174, and the expenditures to \$39,793. The house of refuge, open to boys not exceeding 16 years of age, comprises a farm of 225 acres, a chair factory, and a tailor shop. The number of inmates at the beginning of 1874 was 216; the total expenditures for the preceding year amounted to \$56,244, including \$10,497 for buildings and improvements. This institution is conducted on the "family system," the inmates being divided into families of about 50 each. The plan of the soldiers' orphans' home comprises educational and industrial features. At the close of 1873 the number of inmates was 285; the cost of the institution for the year was \$32,448. In the two state prisons of Indiana the convicts are employed in different branches of industry, prominent among which is the manufacture of agricultural implements and railroad cars. The convicts receive regular instruction in the ordinary English branches, and also have the use of a library. The number of convicts in the northern prison at the close of 1873 was 368; the total receipts of the prison for the year were \$57,465, of which \$50,069 was for labor; the expenditures amounted to \$49,743. The average number of convicts in the southern state prison was 395. The ordinary expenses of the prison for the year amounted to \$66,806, and the total receipts from convict labor and all other sources to \$67,088. Of the 751 convicts in both institutions at the beginning of 1874, 86 had been committed for murder, 18 for manslaughter, 413 for grand larceny, and 21 for forgery; 57 were under sentence for life, and 14 for 21 years. The Indiana reformatory institution for women and girls, which has penal and reformatory departments, was opened in September, 1873. Of the 21 females in the penal department at the beginning of 1874, 5 were under sentence for murder, 1 for manslaughter, 1 for forgery, and the remainder for larceny.—The educational interests of the state are under the general supervision of the state board of education, which comprises the governor, the superintendent of public instruction, the presidents of the state university and the normal school, and the school superintendents of the three largest cities in the state. The more immediate management of the common schools is vested in a state superintendent of public instruction, in county superintendents, and in trustees who have the general charge of educational affairs in cities and towns. The opportunity for obtaining a common school education without charge for tuition is afforded to all persons between the ages of 6 and 21 years; separate schools, however, are provided for negroes, who are not allowed to attend schools designed for white persons. Teachers must be

examined and receive certificates. The permanent common school fund of Indiana in 1874 was greater than that of any other state in the Union; it amounted to \$8,616,931, which yielded an annual interest of \$189,455. This fund consists of a productive portion comprising the congressional township, the saline, the surplus revenue, the bank tax, and the sinking funds; a contingent portion embracing the proceeds of fines, forfeitures, escheats, swamp lands, and taxes on corporations; and a non-productive portion comprising the sixteenth sections (17,882 acres) of the public lands remaining unsold. Besides these sources of revenue, a property tax of 16 cents on the \$100 and a poll tax are levied for school purposes. The income from state taxes in 1873 was \$1,190,626, besides \$530,667 from local taxation. The income from all sources amounted to \$2,276,569, being an increase of \$165,581 over that of the preceding year. The entire school population in 1872 was 640,332; the total enrollment 465,154, of whom 13,895 were in high schools; and the average attendance 298,851. Schools were open in 9,008 districts, the average length throughout the state being $5\frac{1}{2}$ months. There were employed 12,056 teachers, of whom a majority were males. The total valuation of school property in 1872 was \$9,199,480. The normal school was organized in 1867, and in 1873 had 12 instructors and 356 pupils, of whom 228 were in the normal and 128 in the model school. The full course occupies three years. The state university was opened as a college in 1824, and became a university in 1839. It comprises a collegiate, a medical, and a law department, in each of which tuition is free. A department of military science and civil engineering is connected with the collegiate department. Women are admitted to the collegiate course. In 1874 the university had 28 instructors, of whom 12 were in the medical and 2 in the law department, and 371 pupils, including 108 in the medical and 41 in the law department. The 390,000 acres of land granted by congress to Indiana for the establishment of a college of agriculture and the mechanic arts have been sold for \$212,238, which is to be devoted to the support of Purdue university. This institution was founded at Lafayette by Mr. John Purdue, a resident of that city, who gave \$150,000 for the purpose. There are more than 200 acres of land connected with the institution. Among the largest of the institutions of learning not connected with the state are the university of Notre Dame (Roman Catholic) at Notre Dame, St. Joseph co., and the Northwestern Christian university (Disciples') in Indianapolis. The former has a classical and a scientific course of four years each, and a commercial course of two years. It was organized in 1842, and in 1874 had 15 professors, 16 other instructors, and 441 pupils. The Northwestern Christian university, organized in 1854, comprises an academic department which affords a classical

and a scientific course, a business, and a law department. In 1873 there were 13 instructors and 265 students. The Indiana Asbury university (Methodist), at Greencastle, has preparatory, collegiate and law courses. (See GREENCASTLE.) Earlham college (Friends') was founded at Richmond in 1859, and in 1873 had in its collegiate and preparatory departments 11 instructors and 222 students, with 3,500 volumes in the library. Other prominent colleges of the state are represented in the following table:

NAME.	Location.	Date of organization.	Instructors.	Pupils.	Volumes in library.
Salem college.....	Bourbon.....	1870	9

Special instruction in science is afforded at Purdue university and St. Meinrad's college; in theology at Hartsville university (United Brethren); in law at the Indiana university, the Northwestern Christian college, and the university of Notre Dame; and in medicine by the medical department, in Indianapolis, of the state university. Prominent among institutions for the superior instruction of females are St. Mary's academy at Notre Dame, Logansport female college at Logansport, Moravian seminary for young ladies at Logansport, De Pauw college at New Albany, and the Indianapolis female institute in Indianapolis. According to the census of 1870, the total number of educational institutions in Indiana was 9,073, with 11,652 teachers, of whom 4,974 were females, and 464,477 pupils. The income from all sources for educational purposes amounted to \$2,499,511, of which \$50,620 was from endowment, \$2,126,502 from taxation and public funds, and \$322,389 from tuition and other sources. Included in the above were 8,871 public schools, with 11,042 teachers and 446,076 pupils, 16 colleges with 143 teachers and 3,102 pupils, 16 academies with 125 teachers and 3,580 pupils, and 124 private schools with 201 teachers and 6,296 pupils. The total number of libraries was 5,301, containing 1,125,553 volumes; of these, 2,968 with 497,659 volumes were private, and 2,333 with 627,894 other than private, including 20 circulating libraries containing 8,248. The most important libraries are the state library in Indianapolis, which has 15,000 volumes; that of Wabash college, 12,000; university of Notre Dame, 12,000; Whitcomb and college circulating library at Greencastle, 9,000; Hanover college, at Hanover, 7,000; state university at Bloomington, 6,000;

and Northwestern Christian university in Indianapolis, 5,000. The census of 1870 reported 293 newspapers and periodicals, having an aggregate circulation of 363,542 and issuing 29,964,984 copies annually. There were 20 daily, with a circulation of 42,300; 3 tri-weekly, with 2,200; 1 semi-weekly, with 350; 233 weekly, with 239,342; 6 semi-monthly, with 9,200; 28 monthly, with 64,150; and 2 bi-monthly, with 6,000. The statistics of churches were as follows :

—Indiana originally constituted a part of New France, and subsequently of the Northwest territory. The exact period of its first settlement is not ascertained. In 1702 a party of French Canadians descended the Wabash, and established several posts on its banks, and among others Vincennes. The Indians made little opposition to the new comers. Until 1763, when the country was ceded to the English, nothing is known of the early settlers. By the treaty of cession, however, they were confirmed in their possessions. The treaty of 1783 included Indiana in the United States. In 1788 an Indian war broke out, which caused great distress at Vincennes. In 1791 the Indians were attacked at the mouth of the Tippecanoe by Gen. Wilkinson, and by the subsequent victories of Gen. Wayne a dangerous confederacy was broken up and the tribes were obliged to submit. The whole district now began to enjoy that repose of which it had been for many years deprived. By the treaty of Greenville in 1795 the United States obtained several eligible parcels of land, and settlement began to make considerable progress. On May 7, 1800, Ohio was erected into a separate territory, while all the country W. and N. was included in the new government of Indiana. The territorial government was organized July 4, with William Henry Harrison as governor. In

1805 Michigan was also set off, and in 1809 Illinois, leaving Indiana with its present limits. In all this period, however, the Indians had been troublesome, and greatly impeded settlement. Nevertheless the census of 1810 showed a fair increase, the population in that year amounting to 24,520 souls. In 1811 the general government determined to exert its power against the savages, who, excited and exasperated by the eloquence of Tecumseh, a leader of the Shawnees, and the most extraordinary man that had ever appeared among them, had committed grievous depredations. A force of regulars and militia was assembled at Vincennes and placed under the command of William Henry Harrison, then governor. On Nov. 6 of the same year the governor appeared before Prophetstown or Tippecanoe on the Wabash, and demanded restitution of the property which the Indians had carried off. After a conference it was agreed that hostilities should not commence until next morning, that an amicable arrangement might be made; but in violation of this armistice the Americans were attacked before daybreak by a large body of savages. Gov. Harrison, however, knowing the character of the enemy, had so disposed his troops as not to be taken by surprise. The combat that ensued, though short, was unusually severe; the Indians fought with desperate courage, but could not withstand the superiority of the forces arrayed against them, and the fate of the battle was soon decided. After burning the town and laying waste the surrounding country, the victorious army returned to Vincennes, and not long afterward the tribes sued for peace. The war with England now broke out, and gave a fresh impetus to Indian hostility; but again the savages were overwhelmed, and after the close of the war in 1815 finally ceased to molest or trouble the settlers. In December, 1815, the territorial legislature petitioned congress for admission into the Union, and the privilege of forming a state constitution. A bill for these purposes passed congress in April, 1816; and soon after a convention was called, which on June 29 ensuing adopted the first constitution of Indiana. On Dec. 11, 1816, the state was admitted into the Union. A more rapid immigration ensued, and continued without interruption; and though numbers passed westward into Illinois, the new state retained its share. In 1827 the Erie canal opened an outlet for the produce of the west, and the national road was commenced. Both these circumstances naturally stimulated settlement; and the sales of land so rapidly increased that in the ten years ending in 1830 they amounted to 3,558,221 acres. The population in the same year was 343,031, being an increase of 133.1 per cent. over that of 1820. Now commenced that speculation mania which terminated in the financial revulsion of 1837. In 1832 the legislature incorporated eight stock companies for constructing railroads; in 1833 the middle section of the Wabash and Erie

canal was commenced, and in 1834 the state bank with ten branches was incorporated, to which were subsequently added three other branches. The result of these undertakings, and others into which the state entered, was a debt amounting to \$14,057,000 and a general bankruptcy. But in the ten years ending in 1840 the population had doubled, and 9,122,688 acres of public land had been disposed of to individuals; but none of the great works had yet been completed. For the next six or seven years little progress was made, and in no one of these years was 100,000 acres of land disposed of. In 1846 the state debt, on which no interest had been paid since 1839, was consolidated and arranged into two classes, the state debt proper and the canal debt; and means were devised for paying interest on the former. Under the influence of this scheme prosperity returned. In 1851 a new constitution was adopted, and in 1853 the legislature passed a free banking law. The question of holding another constitutional convention was submitted to the people in 1859, when the proposition was rejected.

INDIANA, a W. county of Pennsylvania, bounded S. E. by Conemaugh river and drained by numerous small streams; area, 770 sq. m.; pop. in 1870, 36,138. It has a hilly surface, well timbered, chiefly with white pine, and abounds in iron ore and bituminous coal. The soil is moderately fertile. The Pennsylvania canal passes along the S. boundary, and a branch of the Central railroad extends to the county seat. The chief productions in 1870 were 303,183 bushels of wheat, 97,550 of rye, 652,263 of Indian corn, 906,255 of oats, 71,477 of buckwheat, 77,367 of potatoes, 125,891 lbs. of wool, 1,100,925 of butter, and 38,749 tons of hay. There were 11,586 horses, 12,061 milch cows, 13,844 other cattle, 44,054 sheep, and 17,412 swine; 10 manufactories of agricultural implements, 9 of brick, 14 of carriages, 3 of clothing, 15 of furniture, 10 of iron castings, 1 of machinery, 4 of marble and stone work, 2 of paper, 13 of saddlery and harness, 2 of salt, 4 of sash, doors, and blinds, 11 of tin, copper, and sheet-iron ware, 8 of woollen goods, 8 flour mills, 28 tanneries, 19 currying establishments, 4 planing mills, and 26 saw mills. Capital, Indiana. •

INDIANAPOLIS, the capital and largest city of Indiana, seat of justice of Marion co., situated near the centre of the state, on the W. fork of

White river, 100 m. N. W. of Cincinnati and 165 m. S. S. E. of Chicago, in lat. 39° 47' N., lon. 86° 6' W.; pop. in 1840, 2,692; in 1850, 8,091; in 1860, 18,611; in 1870, 48,244, of whom 10,657 were foreigners (5,286 Germans and 3,321 Irish) and 2,931 colored. The number of families was 9,200; of dwellings, 7,820. The population in 1874 was estimated by local authorities at 80,000. The city is built in the midst of a fertile plain, chiefly on the E. bank of the stream. The surrounding country abounds in black walnut, and in the vicinity is an extensive coal field. The streets are 90 ft. wide, except Washington street, which has a width of 120 ft., and cross each other at right angles; but there are four long avenues radiating from a central square and traversing the city diagonally. There are 200 m. of improved streets, most of them being gravelled, but many paved with stone or wood, and all lighted with gas. A system of sewerage is in progress. The river is crossed by nine bridges (three

State House in Indianapolis.

for railroad purposes), of which all except the old "national road" bridge are of iron. Two others are to be constructed. Street cars accommodate local travel. There are seven parks, viz.: the Circle, in the centre, containing 4 acres and ornamented with shade trees; the state house park, 10 acres; military park, 18 acres; university park, 4 acres; the trotting or southern park, with a course of one mile, 86 acres; a park in the N. portion of the city, embracing 100 acres; and the state fair grounds, with exposition building, containing 40 acres. Greenbaum cemetery is within the city limits, and is coeval with the city itself; 2 m. N. of the city is Crown Hill, which is handsomely laid out and tastefully adorned; and the Catholic cemetery is just S. of the city limits. The state house, in the Doric style, erected in 1835, is 180 ft. long by 80 ft. wide, with a colonnade and dome. The state institute for the

blind was erected in 1847 at a cost of \$300,000; the grounds contain eight acres. The main building has a front of 150 ft. and is five stories high, consisting of a centre and two wings, each surmounted by a Corinthian cupola, the centre also having an Ionic portico. The state lunatic asylum, 1½ m. W. of the city limits, was erected in 1848, and has since been twice enlarged, at an aggregate cost of \$350,000. The principal building has accommodations for 525 patients; the grounds embrace 160 acres, a portion of which is handsomely laid out and adorned. The state institute for the deaf and dumb, just E. of the city limits, was also erected in 1848, and cost \$220,000. The grounds comprise 105 acres, and immediately around the buildings are handsomely laid out, and adorned with trees and shrubbery. The United States arsenal, 1 m. E. of the city, is a handsome building, and is surrounded by grounds containing 75 acres. The union passenger depot, at which all the railroads converge, is 420 ft. long, and is one of the most spacious and convenient structures of the kind in the country. Other prominent public buildings are the post office, governor's residence (occupied by public offices), court house, county jail, city hall, city prison, academy of music, odd fellows' hall, masonic hall, and several of the churches. A new court house, costing about \$800,000, is nearly completed, and the erection of a new state house, to cost about \$4,000,000, has been authorized by the legislature. The city has railroad connection with all parts of the state and with the principal cities of the west. The lines centring here are 10 in number, viz.: the Cincinnati, Hamilton, and Indianapolis; Cleveland, Columbus, Cincinnati, and Indianapolis; Indianapolis, Bloomington, and Western; Indianapolis, Cincinnati, and Lafayette; Indianapolis, Peru, and Chicago; Indianapolis and St. Louis; Indianapolis and Vincennes; Pittsburgh, Cincinnati, and St. Louis; St. Louis, Vandalia, Terre Haute, and Indianapolis; and Jeffersonville, Madison, and Indianapolis. The Indiana and Illinois Central railroad is rapidly approaching completion, and a belt line, encircling the city and connecting all the other lines, is in progress. The number of passenger trains daily leaving and arriving is 78. The number of freight cars forwarded in 1873 was 296,314; received, 286,820. The first impulse to the growth of Indianapolis was the completion of the Madison railroad in 1847. The civil war concentrated a vast temporary business here, the effects of which were largely permanent. The trade is extensive, the aggregate sales of merchandise in 1873 amounting to \$50,830,000. The sales in 1870 were \$36,969,102; in 1871, \$41,851,657; in 1872, \$49,774,789. There is a large grain elevator on the W. side of the river, erected in 1873; several smaller ones have been in operation for some years. The sales of real estate in 1871 amounted to \$7,995,513; in 1872, to \$16,326,450; and in 1873, to \$32,579,253. More than

half of the purchases have been for occupancy. The total cost of buildings erected in 1873 was about \$5,000,000. The manufactures are varied and important. The amount of capital invested in 1873 was \$11,006,000; number of hands employed, 8,175; value of products, \$28,012,740. The statistics of the principal branches are contained in the following table:

MANUFACTURES.	Capital.	Hands.	Products.
Agricultural implements	\$400,000	185	\$955,000
Bakery products	44,500	90	802,700
Brewery products	125,000	45	317,000
Carriages	285,000	310	897,000
Cars	250,000	150	125,000
Clothing	190,000	301	787,000
Confectionery	108,000	73	317,000
Cotton goods	100,000	83	300,000
Flouring mill products	385,000	96	1,926,000
Furniture, &c.	482,000	424	850,000
Glass	185,000	45	250,000
Hog products	2,000,000	500	7,614,000
Iron founderies & machine shops	878,000	633	1,421,000
Iron, malleable	115,000	70	1,175,000
Iron, rolling mills	900,000	475	1,850,650
Oils, linseed, lard, and lubricating	156,000	36	654,000
Planing mill products	482,000	327	879,000
Publishing and binding	600,000	900	1,250,000
Pumps	125,000	128	292,000
Saws	100,000	75	150,000
Starch	25,000	67	100,000
Sewing machines	160,000	200	400,000
Staves	117,000	235	527,000
Stoves	185,000	165	388,000
Tannery products	78,000	22	260,000
Wheels	250,000	300	500,000
Woolens	295,000	118	650,000

The number of hogs slaughtered was 555,766. The value of manufactures in 1872 was \$19,671,832. There are six national banks, with an aggregate capital of \$3,000,000; two state banks, with \$800,000 capital; two savings banks, and three insurance companies.—The city is divided into 13 wards, and is governed by a mayor and a council of 26 members. There is a well organized fire department and an efficient police force, and the city is well supplied with water. The taxable value of property in 1860 was \$10,000,000; in 1865, \$20,144,447; in 1870, \$27,000,000; in 1871, \$27,999,170; in 1872, \$34,760,871; in 1873, \$65,000,000, the large increase being partly due to a change in the system of valuation. The city debt is about \$1,000,000, and the rate of taxation \$1 10 on \$100. The principal charitable institutions are an asylum for white orphans, supported partly by a city appropriation, and partly by donations; an asylum for colored orphans and a "home for friendless women," supported in the same way; a German orphan asylum, with capacity for 300 inmates; a Catholic female reformatory and asylum, a Catholic infirmary for gratuitous relief of the suffering poor, two societies for the general care of the poor, a large, well conducted city hospital, and a pest house. The reformatory for women and girls and prison for female offenders occupies a commodious structure just E. of the city. The Northwestern Christian university, chartered in 1850, occupies a handsome Gothic building in the N. E. portion of

the city; it admits both sexes, and in 1872-'3 had 13 professors (3 in the law school), 265 students (law department, 10; business department, 50), and a library of 5,000 volumes. The medical department of Indiana university (with which is connected a free dispensary), situated here, was organized in 1869, and in 1872-'3 had 12 professors and 101 students. The city possesses an excellent and well organized system of public schools, embracing the various grades from primary to high school, and including a training or normal school. There are 20 school buildings, of which 10 will accommodate 750 pupils each. The high school will accommodate 550. The value of school property in 1864 was \$88,500; number of children of school age, 6,863, of whom 1,050 attended public schools. In 1874 the value of school property was \$691,256; children of school age, 19,125, of whom 9,868 attended the public schools. There are also a Catholic theological seminary, a Catholic boys' school, and a female seminary conducted by the "Sisters of Providence," recently opened and occupying a splendid building. The state library contains 15,000 volumes. A free city library was opened in April, 1873, in the high school building; it now contains over 14,500 volumes, and a separate building is to be erected for its accommodation. There are 6 daily (1 German) and 13 weekly (5 German) newspapers, and 13 monthly periodicals, one of which, the "National Crop Reporter," has recently been removed from Jacksonville, Ill. The churches, 64 in number, are as follows: 8 Baptist, 5 Christian, 2 Congregational, 5 Episcopal, 1 Friends', 16 Methodist, 10 Presbyterian, 4 Roman Catholic, 1 Swedenborgian, 2 Unitarian, 2 Universalist, and the rest miscellaneous, some of which have no church edifice.—Indianapolis was first settled by John Pogue in March, 1819, and in about a year from that time it numbered 15 families. It was chosen as the seat of the state government in January, 1821 (though the capital was not actually removed from Corydon till 1825), and at the same time the legislature gave it its present name and appointed commissioners to lay it off as a town. It was incorporated in 1836, and received a city charter in 1847.

INDIAN ARCHIPELAGO, or **Malay Archipelago**, a vast aggregation of insular groups S. E. of the continent of Asia, lying between the China sea, the Indian ocean, and the Pacific. In the widest sense it includes the Philippine islands and Papua, and extends from about lon. 95° to 151° 20' E., and from lat. 19° 40' N. to about 11° S., being about 2,100 m. wide and upward of 4,000 m. long, and bisected by the equator. With the exception of Australia, the Indian archipelago contains the largest islands of the world, namely, Borneo and Papua. These, together with Gilolo, Celebes, and Sumatra, form a range extending along the equator, and all except Papua crossed by it; a similar but shorter range, further S., is made up mainly of Java,

Sumbawa, Flores, and Timor; and in the north the principal islands are Mindanao and Luzon, of the Philippine group. The seas which separate the islands are variously designated. These are: the Java sea, between Java and Borneo; the Sooloo sea, between Borneo and the Philippines; the Celebes sea, between the Philippines and Celebes; the Flores sea, between Celebes and the Timor group; and the Banda sea, between Celebes and Papua. The depth of water between the Asiatic mainland and Sumatra, Java, and Borneo, respectively, nowhere exceeds 100 fathoms, nor is the sea between Papua and Australia deeper than this; but these shallow seas are divided by a line of deep water in which lie Celebes, the Moluccas, Flores, and the adjacent islands. Wallace regards the archipelago as naturally comprehending the Malay peninsula, S. of Tenasserim, the Nicobar islands, and the Philippines. Exclusive of the latter, he classifies its islands into five groups, as follows: 1, the Indo-Malay islands, comprising the Malay peninsula and Singapore, Borneo, Java, and Sumatra; 2, the Timor group, comprising the islands of Timor, Flores, Sumbawa, and Lombok, with several smaller ones; 3, Celebes, comprising also the Sula islands and Booton; 4, the Moluccan group, comprising Booro, Ceram, Batchian, Gilolo, and Morty, with the smaller islands of Ternate and Tidore, Makian, Kaioa, Amboyna, Banda, Goram, and Matabello; and 5, the Papuan group, comprising Papua, with the Ar- roo islands, Mysol, Salawaty, Waigioo, and several others. The area in English square miles of some of the principal islands is approximately as follows:

Amboyna	300	Ceram	6,500
Bali	2,200	Flores	9,000
Banca	5,000	Gilolo	5,500
Banda	130	Java and Madura	51,200
Batchian	800	Lombok	1,850
Booro	2,000	Sumatra	160,000
Borneo	300,000	Sumbawa	6,000
Celebes	70,000	Timor	11,500

It will be seen that neither Papua nor the Philippines are embraced in this table. The latter islands are chiefly under the dominion of Spain, but in the other parts of the archipelago the government of the Netherlands is the predominant power. According to the latest returns, principally of 1871-'2, the colonial possessions of the Dutch in the archipelago have an aggregate area of about 600,000 sq. m. and a total population of 24,300,000. They comprise the whole of the island of Java, extensive territories in Borneo, Sumatra, and the Moluccas, and about 29,000 sq. m. in Papua.—Physically, the most striking and characteristic division of the archipelago is into volcanic and non-volcanic regions. A long line of active and extinct volcanoes, constituting one of the most remarkable volcanic systems in the world, extends from Sumatra eastward through Java, Bali, Lombok, Sumbawa, Flores, and Timor, beyond which it trends northward through Banda, Amboyna, and Gilolo to the northern

peninsula of Celebes, and thence to the Philippine islands. The islands traversed by this belt are subject to frequent earthquakes. The non-volcanic regions lie on both sides of it. There are no volcanoes in Papua or Borneo, and in the latter island earthquakes are unknown. The loftiest mountains in the archipelago are in Java, Borneo, and Sumatra, where numerous peaks rise to a height of 10,000 ft. and some much higher. The climate is one of almost uniform tropical warmth and moisture, giving rise to a dense and luxuriant forest growth, which overspreads all the islands except Timor and those immediately around it; in these there is a deficiency of rain, which is attributed to the proximity of the arid regions of Australia. The line of separation between the two great zoological provinces, known as the Indian and the Australian, divides the archipelago, passing between Celebes and Borneo, and through the narrow strait of Lombok. This is but 15 m. wide, yet, according to Lyell, the contrast between the animals on the two sides of this channel is as great as between those of the old and new worlds. W. of it the fauna is strictly Indian; E. of it a distinctively Australian fauna is met with; and it is conjectured that the two great regions thus distinguished once formed parts of the Asiatic and Australian continents respectively. The geographical distribution of the two typical races of men inhabiting the archipelago corresponds closely to that of the animals; the Indo-Malays being found in the western islands, while the Papuans dwell further eastward.—Detailed accounts of the principal islands of the Indian archipelago will be found under their respective titles. For their general history, see "The Indian Archipelago, its History and Present State," by Horace St. John (2 vols. 12mo, London, 1853). The natural history of the region is ably treated in "The Malay Archipelago," by Alfred Russel Wallace (London, 1869). See also "Travels in the East Indian Archipelago," by Albert S. Bickmore (8vo, New York, 1869).

INDIAN BEAN. See CATALPA.

INDIAN CORN. See MAIZE.

INDIAN CRESS. See NASTURTIUM.

INDIAN CUCUMBER, a name given to *Medeola Virginica*, a common and striking plant of the lily family, which is found in May and June in rich damp woods from Canada to Florida. The remarkably white tuberous root stock is about 2 in. long and $\frac{1}{2}$ in. thick, and has the taste of cucumber; it is said to have been eaten by the Indians, whence the common name. The simple slender stem, 1 to 3 ft. high, is partly clothed with a whitish wool which readily separates; near the middle it bears a whorl of five to nine obovate, lanceolate, pointed thin leaves; at the summit are the flowers, immediately below which is another whorl of, usually, three smaller leaves. The flowers (three to six) have three petals and three sepals, all of the same greenish yellow color, and recurved;

stamens six, pistil one with three long thread-like brownish styles diverging from the top of the globose ovary, which in ripening forms a dark purple berry of the size of a pea. The

Indian Cucumber (*Medeola Virginica*).

botanical name is the diminutive of *Medea*, the sorceress, probably given to the plant on account of reputed medicinal powers; it really possesses very little activity, though the elder Barton thought it serviceable in dropsy.

INDIAN DYE. See PUCCOON.

INDIAN FIG (*Opuntia vulgaris*). See CACTUS.

INDIAN HEMP. I. A variety of hemp produced in India, formerly supposed to be a distinct species, and called *cannabis Indica*. (See

Indian Hemp (*Apocynum cannabinum*).

HEMP, vol. viii, p. 632.) II. An American perennial herb, *apocynum cannabinum*, of the order *apocynaceae*, or dogbane family. The plant throws up several branching stems, 2 to

3 ft. high, with opposite, mucronate leaves, which are smooth or downy, and numerous, many-flowered cymes. The flowers are small, bell-shaped, greenish white, the corolla with five triangular appendages in the throat; stamens five, inserted on the base of the corolla, and slightly adhering to the stigma by their filaments; fruit of two long slender follicles with silky tufted seeds. It has a milky juice, and the bark has an exceedingly tough fibre, the use of which by the aborigines for making cordage, fishing nets, &c., no doubt gave it the common name. We know of no extensive experiments in utilizing this fibre, which is whiter and stronger than that of hemp. The root of this plant is sometimes used in medicine, it being powerfully emetic and cathartic in doses of 15 to 30 grains of the powdered dry root, or a similar amount in the form of a decoction; it has been found efficacious in dropsy. It grows in most of the states, and has other local names; in South Carolina it is known as Gen. Marion's weed, as that leader is said to have used it in the diseases of his camp. Another species, *A. androsamifolium*, equally common, is a more spreading plant, with much larger pale rose-colored flowers, and used as a prompt emetic; it is known as dogbane and bitter-root.

INDIAN LANGUAGES, American. See AMERICAN INDIANS, LANGUAGES OF THE.

INDIAN OCEAN, the third in size of the oceans of the world. It is bounded N. by Asia, N. E. by the Malay peninsula and the Sunda islands, E. by Australia and the meridian of Cape Leeuwen on the S. W. coast of that continent, S. by the Antarctic circle, and W. by Africa and the meridian of the cape of Good Hope. The south China sea and all the waters south and west of the Philippine isles and New Guinea are sometimes included in the limits of the Indian ocean; but they are much more properly apportioned to the Pacific basin, the Sunda islands and Malay peninsula representing the isthmus connecting the northern and southern halves of the continent of Asia-Australia. The southern limit, and the eastern and western S. of the continents of Australia and Africa, are of course entirely artificial. The northern shore of the Indian ocean is deeply indented by the peninsula of India, forming two large bays, the Arabian sea and the bay of Bengal. Two considerable gulfs, or more properly inland seas, are in communication with this ocean, the Red sea and the gulf of Persia. It is not rich in islands, of which only two, Madagascar and Ceylon, are of considerable size. The smaller ones constitute mostly archipelagoes, such as the Comoro, Mascarene, Amirante, Seychelles, Maldivé, Laccadive, Andaman, Nicobar, Chagos, and Keeling islands, in the tropics, and the Kerguelen, Crozet, and Macdonald islands, in the colder southern part. There are also a few isolated volcanic islands, such as New Amsterdam and St. Paul. Most of the tropical islands are of coral formation; a few

are volcanic with fringing or barrier reefs, such as the Mascarene and Andaman islands. The Asiatic coast is mostly free of coral, but there are some fringing reefs on the coasts of Ceylon and Madagascar, Africa, and the Red sea. The only important African river falling into this ocean is the Zambesi. Asia contributes the united stream of the Euphrates and Tigris, the Indus, Ganges, Brahmapootra, and Irrawaddy; Australia almost nothing. The system of currents is rather complicated, but in its main features resolves itself into a revolving current moving from right to left, as in all the ocean basins of the southern hemisphere. The equatorial part of it, the S. E. trade current moving from E. to W., is very broad, its middle being about lat. 15° S., but it does not really reach the equator. It strikes the coast of Madagascar, dividing into two branches. The one passing N. of that island bends S. through the Mozambique channel, forming the powerful and warm current of the same name; it is joined again by the S. branch near the coast of Africa, forming the Agulhas current off the cape of Good Hope, which after barely passing that cape turns back sharply to the south and east, and forms with the antarctic drift the retrograde current in lat. 37° to 42° S. Before reaching Australia it divides into the S. and E. Australian currents, the latter completing the circuit by re-entering the S. E. trade current after giving off branches running into the Java and Flores seas and Torres straits. The N. equatorial current is overcome by the monsoons, and, under the name of Malabar current, flows westward from October to April, and eastward from April to October. It extends from the coast of Africa around Ceylon into the bay of Bengal. A narrow retrograde current has been observed flowing E. across this ocean, nearly under the equator or a little S. of it. The monsoons prevail from its northern limit to lat. 8° S. North of the equator the N. E. monsoon blows from October, to April, the S. W. prevails in the other half of the year; while S. of it the N. W. monsoon blows while the N. E. is blowing on the N. side, and *vice versa*. Between the limits of lat. 10° and 28° S., the S. E. trade wind blows from April to October. South of these are the constant N. W. winds, which prevail almost in the same latitudes as in the Atlantic and Pacific oceans. The periods at which these winds change are marked by violent tempests, and the region between lat. 5° and 40° S. is greatly subject to hurricanes. They range usually between lat. 9° and 35° S., extending from Madagascar to the island of Timor; they come generally from the N. E. near Java, and travel S. W. and S., returning again E. The depth of the sea is greatest near the S. coasts of Asia; the Arabian sea is from 2,000 to 2,500 fathoms deep; the bay of Bengal averages nearly 2,300 fathoms. Opposite the Hoogly river, in the bay of Bengal, is a sudden and deep depression in the ocean bed, called

"the bottomless pit." Near the S. E. coast of Africa the depth varies from 1,300 to 1,900 fathoms.—The northern part of the Indian ocean is the theatre of an immense navigation, nearly the whole commerce of Europe and America with China and India and the great Malay archipelago passing over its waters; while between Arabia and Persia on the west and India on the east an extensive trade is carried on in native vessels, the origin of which dates from the remotest antiquity. The great Pacific railroad, opened in 1869, has deprived the Indian ocean of some of its navigation; but the Suez canal, which was opened a few months later, is expected to increase it. The European-Indian commercial navigation amounted in 1872 to nearly 12,000,000 tons. The southern part of this ocean is comparatively little frequented, being almost destitute of islands. It is traversed chiefly by vessels going to Australia and New Zealand by way of the cape of Good Hope. The chief ports of the Indian ocean and its tributary gulfs and rivers are Mozambique and Zanzibar in Africa, Aden and Mocha in Arabia, Bassorah in Turkey, Bushire in Persia, Bombay, Surat, Madras, and Calcutta in India, and Trincomalee and Pointe de Galle in Ceylon.

INDIANOLA, a town and the capital of Calhoun co., Texas, port of entry of the district of Saluria, on the W. shore of Matagorda bay, 140 m. S. by E. of Austin, and 120 m. S. W. of Galveston; pop. in 1870, 2,106, of whom 492 were colored. It is the terminus of the Gulf, Western Texas, and Pacific railroad (completed in 1873 to Cuero, De Witt co., 66 m.), which is to connect it with Austin and San Antonio. Steamers run regularly to Galveston and Corpus Christi. The commerce is important. For the year ending Aug. 31, 1872, there were entered in the coasting trade 242 vessels of 188,453 tons, of which 149 of 174,270 tons were steamers; cleared, 250 vessels of 194,896 tons, of which 146 of 170,052 tons were steamers. The receipts were 5,808,000 feet of lumber and 2,750,000 shingles; shipments, 27,461 head of animals, 11,549 bales of cotton, 330,875 hides, and 3,234 bags of wool. The value of imports from foreign ports was \$82,463; of exports to foreign countries, \$58,658. A weekly newspaper is published.

INDIAN POKE. See HELLEBORE.

INDIANS. See AMERICAN INDIANS.

INDIAN SHOT, a popular name for species of *canna*, especially *C. Indica*, which was for a long time the only one generally cultivated. *Canna* (from the Celtic *cann*, a cane) was formerly placed in the same family with the ginger and the banana, but botanists now make an order, the *cannaceae*, which includes this, the arrowroot, and some other less known plants. The cannas have large, fleshy root stocks, tall stems, clothed with large showy leaves, and bearing at the summit a spike of often handsome flowers of various shades of yellow, scarlet, and crimson; the flowers are irregular in structure; they have three outer colored di-

visions or calyx, within which are three parts corresponding to a corolla with a single stamen which has a petal-like filament and bears an anther on its margin; pistil with a petal-like style and a three-celled ovary, which in ripening becomes a several-seeded very rough pod; the seeds are round, hard, and black, and sufficiently shot-like in appearance to warrant the common name. One species, *C. flaccida*, is found in swamps along the coast from South Carolina southward; it grows 4 ft. high and has yellow flowers 3 or 4 in. long. The tubers of some species are edible and used as a table vegetable, while others have slight medicinal properties; the kind of arrowroot called *tous les mois*, chiefly used by the French, is made in the island of St. Christopher from the rhizomes of a canna, supposed to be *C. edulis*. The great interest possessed by the cannas is due to their effectiveness as decorative plants. Since beauty of form and stateliness of habit

Indian Shot (*Canna Indica*).

have come to be properly appreciated in gardening, great improvement has been made in cannas, and cultivators, especially those in the south of France, have by hybridizing and crossing obtained splendid results. In the now valued kinds the original species is lost, and they are known by garden rather than botanical names. There are now varieties from 2 ft. to 8 and 12 ft. high, with a remarkable diversity of foliage; in some the leaves are narrow, stiff, and erect, in others broad, very long, and graceful, while their shades of color vary from light glaucous green to blackish purple. While some are valued for their fine foliage only, others produce an abundance of handsome flowers, which have also been improved, and there can be nothing more effective than a well arranged group of the finer varieties of canna. The choice varieties are multiplied by division, and plants are readily raised from seed, which may or may not be like the parent; the seeds should

be scalded, and sown in a hotbed; they will germinate in the open ground, but the plants will not acquire much size the first year. The roots should be taken up at the first frost and kept in a dry place where they will not freeze; the next spring they are to be divided and set out when the soil has become warm.

INDIAN TERRITORY, an unorganized portion of the United States, situated between lat. 33° 35' and 37° N., and lon. 94° 20' and 103° W.; length E. and W. along the N. border 470 m., and S. of lat. 36° 30' about 310 m.; breadth W. of the 100th meridian 35 m., and E. of that line about 210 m.; area, 68,991 sq. m. It is bounded N. by Colorado and Kansas, E. by Missouri and Arkansas, S. by Texas, from which E. of the 100th meridian it is separated by the Red river, and W. by Texas and New Mexico. The inhabitants are not regularly enumerated in the census of 1870, but the superintendent, from inquiries made through the agents of the Indian office, states the population at 68,152, of whom 2,407 were whites, 6,378 colored, and 59,367 Indians. Of the Indians, 24,967 were on reservations or at agencies, and 34,400 were nomadic. Besides a considerable portion still unassigned, the territory contains 17 Indian reservations. The Cherokees occupy an area of 5,960 sq. m. in the northeast, E. of the 96th meridian, and bordering on Kansas and Arkansas; they also own a strip about 50 m. wide along the Kansas border from the Arkansas river W. to the 100th meridian, about 8,500 sq. m. The Choctaw reservation, 10,450 sq. m., is in the southeast, bordering on Arkansas and Texas. Joining this on the west, and separated from Texas by the Red river, is the Chickasaw reservation, 6,840 sq. m. The Creeks occupy 5,024 sq. m. in the E. central part of the territory, bordering on the Cherokees and Choctaws. S. W. of the Creeks is the Seminole reservation, 312½ sq. m., and N. of this the reservation of the Sacs and Foxes, 756 sq. m. W. of the Seminole reservation is a tract of 900 sq. m. upon which are settled the citizen Pottawattamies and the Absentee Shawnees. The Osage reservation, 2,345 sq. m., is W. of that of the Cherokees, and is bounded N. by Kansas and S. W. by the Arkansas river. N. W. of the Osages, and bounded N. by Kansas and W. by the Arkansas, is the reservation of the Kaws, 156 sq. m., to which they were removed from Kansas in the summer of 1873. In the S. W. part of the territory, and bounded E. by the Chickasaws, are the Kiowas, Comanches, and Apaches, occupying 5,546 sq. m.; and N. of these are the Arapahoes and Cheyennes, with 6,205 sq. m. The Quapaws, the confederated Peorias, Kaskaskias, Weas, Piankeshaws, and Miamies, the Ottawas, the Shawnees, the Wyandots, and the Senecas severally have reservations, with an aggregate area of 297 sq. m., in the N. E. corner of the territory, E. of the Neosho river. The affiliated bands of Wichitas, Keechies, Wacoos, Tawacanies, Caddoes, Ionies, Dela-

wares, and Penetethka Comanches are gathered at an agency on the Washita river W. of the Creek country, but they have no reservation. The Modocs (remnant of Captain Jack's band) and about 400 Kickapoos and Pottawattamies (from the border of Texas and Mexico) were removed to the Indian territory in the latter part of 1873. The former were placed temporarily on the Shawnee reservation, and the latter were settled on a tract on the Kansas border W. of the Arkansas river.—The surface has a general declination toward the east, but the only considerable elevations are the Wichita mountains in the southwest, and a continuation of the Ozark and Washita mountains from Arkansas in the east. Otherwise the E. portion of the territory and that S. of the Canadian river spreads out into undulatory plains, while the N. W. portion consists of elevated prairies. It is watered by innumerable streams, tributaries of the Arkansas and Red rivers. The former flows from Kansas in a S. E. direction through the N. E. corner of the territory into Arkansas, and is navigable in high stages of water to Fort Gibson in the Cherokee country. On the east its principal tributaries are the Verdigris, the Neosho, and the Illinois, which have a S. course. On the west the two principal branches are the Canadian and the Red fork. The Canadian river rises by two forks in New Mexico, which flow E., the S. fork first through the N. W. projection of Texas, traverse nearly the whole length of the territory, and uniting join the Arkansas near the E. border. The Red fork enters the territory from Kansas under the name of the Cimarron, and flowing S. E. joins the main stream N. of the Canadian. N. of the Red fork and having the same general direction is the Salt fork or Little Arkansas. The chief tributary of Red river is the Washita, which rises in N. W. Texas, and flowing S. E. joins the main stream near the S. E. angle of the Chickasaw country. Other affluents of Red river, commencing at the east, are the Kimishi, Boggy creek, Blue river, Mud creek, Beaver creek, Cache creek, and the North fork. Red river is navigable by small steamers in ordinary stages of water along nearly the whole S. border. In the west and northwest are extensive deposits of gypsum, and in the Cherokee country are found coal, iron, good brick clay, marble in places, and yellow sandstone suitable for building purposes. The climate is mild and salubrious, but generally dry. The mean annual temperature in the S. E. is 60°; in the N. W. 55°. The annual rainfall, which in the S. E. extremity of the territory is 52 in., decreases to 35 in. in the central region, and is less than 20 in. in the N. W. corner. The Wichita range is intersected by many fertile valleys abounding in wood, water, and grass, and generally the country S. of the Canadian is interspersed with prairie and timbered land, possessing a fertile soil overgrown with nutritious grasses. The N. E. portion of the territory is well wooded, and while there is consid-

erable arable and productive land, much of it is rocky and only fit for timber or pasture; three fifths of the Cherokee country is of this character. Between lon. 97° and 98° a narrow strip of timber, called the "Cross Timbers," stretches from the Red fork of the Arkansas S. and S. W. into Texas. W. of this and N. of the Canadian is a sterile region, scantily overgrown with grass, producing only a few stunted shrubs, cactuses, &c., and covered in places with saline deposits. The most common trees and shrubs are the cottonwood, oak, sycamore, elm, walnut, ash, yellow pine, pecan, Osage orange, hawthorn, and the grape vine. Indian corn is the chief crop. Wheat is also raised, as well as rye, oats, beans, pumpkins, potatoes, and other vegetables, and upland rice. Cotton was for-

merly largely cultivated S. of the Canadian and on the Arkansas and Red rivers, and is still grown there to some extent. Apples do well N. of the Canadian and Arkansas, and peaches, pears, plums, cherries, and small fruits flourish. Among wild animals may be mentioned the prairie dog, the deer, and vast herds of buffalo and wild horses that roam over the W. plains. Wild turkeys are abundant. Large herds of horses and cattle were formerly owned by the Cherokees and other civilized tribes, but they were dispersed and driven off during the civil war, which prostrated the industries of the Indians, and from the effects of which they have not yet recovered. The following table is compiled from the report of the commissioner of Indian affairs for 1873:

TRIBES.	Acres of land cultivated.	Wheat, bushels.	Indian corn, bushels.	Oats, bushels.	Potatoes, bushels.	Hay, tons.	Lumber sawed, feet.
Cherokees.....	89,250	69,650	629,000	35,000	10,000	50,000	480,000
Chickasaws.....	50,700	10,000	75,000	10,000	35,000	25,000	50,000
Choctaws.....	50,000	10,000	100,000	10,000	60,000	50,000	3,000,000
Creeks.....	31,000	600	500,000	1,000	75,000	10,000
Quapaws, &c.....	4,571	2,134	64,742	3,250	4,110	1,875
Seminoles.....	7,600	150,000	4,000	400	50,000
Other tribes.....	5,369	190	81,210	1,500	10,360	1,470	350,468
Entire territory.....	217,790	92,574	1,599,952	60,750	198,470	188,745	3,930,468

There were also raised 5,000 bushels of barley, 10,936 of beans, 1,534 of peas, 6,500 of turnips, 25 of rice, 4,000 lbs. of sugar, and 5,000 bales of cotton (2,000 by the Chickasaws and 3,000 by the Choctaws). The value of furs sold was \$193,560. The productions in 1872 were 100,420 bushels of wheat, 6,562,540 of Indian corn, 104,939 of oats, 281,000 of potatoes, 700 of beans, 1,000 of rice, 27,624 tons of hay, 1,200 lbs. of tobacco, 36,000 gallons of sorghum molasses, and 570 bales of cotton. The total value of productions was \$4,168,932, viz.: Cherokees, \$1,923,155; Chickasaws, \$219,000; Choctaws, \$1,119,797; Creeks, \$537,325; Quapaws, &c., \$30,881; Seminole, \$159,500; other tribes, \$179,274. There were 2,350,000 feet of lumber sawed (2,000,000 by the Cherokees). The value of furs sold was \$102,020, chiefly by the Cheyennes and Arapahoos, Osages, Kiowas, &c. The number and value of live stock in 1873 were as follows:

which crosses the E. part, and the Atlantic and Pacific, from Pacific, Mo., on the Missouri Pacific, to a junction with the Missouri, Kansas, and Texas, at Vinita in the Cherokee country. The total mileage in the territory is 269.—Indian territory forms the greater part of the central Indian superintendency, and contains 11 agencies, viz.: the Cherokee, Choctaw (including also the Chickasaws), Creek, Kaw, Kiowa, Neosho (Osages), Quapaw, Sac and Fox (including also the Absentee Shawnees), Seminole, Upper Arkansas (Cheyennes and Arapahoos), and Wichita; for each of which an agent is appointed by the president with the consent of the senate, to represent the United States; but each tribe has its own internal government. The jurisdiction of the United States courts for the W. district of Arkansas extends over the territory in civil actions where a white man is a party, in case of crimes committed by or upon a white man, and in proceedings for violation of the laws regulating trade and intercourse with the Indians. The subject of a territorial government has been much discussed both among the Indians, who in a general council in 1870 framed a constitution, and in congress; but difference of views between congress and the tribes has hitherto prevented its organization. The United States have adopted the policy of settling the various Indian tribes in this region as far as practicable upon separate reservations, where they may be free from the encroachment of the whites, and under the general superintendence and protection of the government. The greater part of the inhabi-

TRIBES.	Horses.	Cattle.	Sheep.	Swine.	Value.
Cherokees.....	15,000	103,302	3,050	68,868	\$1,861,638
Chickasaws.....	35,000	50,000	2,000	75,000	1,354,000
Choctaws.....	100,000	100,000	8,000	150,000	3,316,000
Creeks.....	15,000	35,000	100,000	1,150,000

The railroads in the territory are the Missouri, Kansas, and Texas (from Sedalia, Mo., on the Missouri Pacific line, to a junction with the Houston and Texas Central, at Denison, Tex.),

tants have thus at various periods been removed from different parts of the Union, but some are indigenous to the territory. Some tribes, as the Kiowas and Comanches, are still in a wild state, while others, as the Cherokees, Choctaws, and Creeks, are well advanced in civilization. The capital of the Cherokee nation is Tahlequah; of the Chickasaws, Tishemingo; of the Choctaws, Armstrong Academy; of the Creeks, Okmulkee; of the Seminoles, We-wo-ka. The following table from the report of the commissioner of Indian affairs gives the population, value of property, number of schools, &c., for 1873:

TRIBES.	Popula- tion.	Value of individual property.	No. of schools.	Teachers.	Scholars.
Cherokees.....	17,217	\$5,000,000	63	65	1,884
Chickasaws.....	6,000	2,000,000	13	18	430
Choctaws.....	16,000	4,748,000*	50	52	1,129
Creeks.....	13,000	3,113,200*	34	43	700
Quapaws, &c.....	1,219	219,341	4	4	203
Seminole.....	2,438	400,500	4	4	157
Other tribes.....	16,594	1,543,598	8	30	266
Entire territory..	72,468	\$17,022,589	176	216	4,769

The second column does not include the value of land, which is held in common, nor of stocks and funds held in trust by the United States under treaties with various tribes, the interest on which is annually paid to such tribes for the support of schools or for general purposes. Most of the schools are supported by the tribal funds, but some are carried on by the missionaries. In 1872 (no returns from the Chickasaws and Choctaws) there were 598 frame and 8,823 log houses, viz.: Cherokees, 500 frame and 3,500 log; Creeks, 35 frame and 4,200 log; Seminoles, 500 log houses; other tribes, the rest. The Cherokees have an orphan asylum with 90 inmates. Three weekly newspapers are published in the territory, one (English and Cherokee) at Tahlequah, the other two in the Choctaw country, one (English and Choctaw) at New Boggy, and one (English) at Caddo. On March 1, 1873, there were 28 post offices, viz.: Cherokee country, 6; Chickasaw, 4; Choctaw, 12; Creek, 4; Seminole, 1; Kiowa, &c., 1. Under the existing regulations of the Indian bureau, the agents of the Cherokees and Creeks are nominated by the Baptists; of the Choctaws and Chickasaws, and the Seminoles, by the Presbyterians; of the other tribes, by the Orthodox Friends. The Methodists, Presbyterians, and Baptists have each several missions, and one or more are maintained by the Friends, Moravians, and Roman Catholics. According to the report of the board of Indian commissioners for 1872, there were 7,170 church members, viz.: Cherokees, 2,450; Choctaws and Chickasaws, 2,500; Creeks, 2,050; Seminoles, 90; other tribes, 80.—The act of June 30, 1834, regulating trade and intercourse with

* Report of the board of Indian commissioners for 1872.

the Indians, declares that "all that part of the United States W. of the Mississippi, and not within the states of Missouri and Louisiana, or the territory of Arkansas," shall for the purposes of that act be considered the Indian country. The vast region thus defined, identical with the then territory of Missouri, formed part of the Louisiana purchase from France in 1803. Reduced by the successive formation of states and territories, the remainder now constitutes the whole of the district described at the beginning of this article except the narrow strip W. of the 100th meridian, which was ceded by Texas to the United States, and is classed geographically with the Indian territory for convenience. (For further information, see the articles on the different tribes.)

INDICTMENT (said to be derived, through the French *enditement*, *enditer*, from the Latin *indicare*, to point out, or, as some suppose, from *indicare* and *indictus*), a written accusation of an offence, preferred to, and presented upon oath as true by, a grand jury. Indictments are to be preferred in criminal matters only, and they lie for all treasons and felonies, for all misprisions (that is, concealments) of treasons and felonies, and for all misdemeanors of a public nature. The course of procedure is this: Upon information by parties who are cognizant of the criminal acts alleged, an indictment is framed by the proper prosecuting officers, and laid before the grand jury. If the jurors, after hearing the evidence, do not find "a true bill," the party, if in custody, is entitled to be discharged without further answer. If the bill, on the contrary, be found to be a true bill, it is returned into court, and the party stands indicted and may be required to answer to the charges made against him. (See JURY.) In respect to its form, the indictment is intended to be a plain and certain narrative of the offence charged, and of the necessary circumstances that concur to ascertain and define the fact and its nature. It can perhaps be no longer made a reproach to the law that it demands, in the words of Chief Justice Hale, "unseemly niceties" in the framing of indictments, and yet the reason for and requirement of singular exactness still remain. In the first place, it is the plain right of the accused to know that he has been legally indicted. To this intent, the bill must show with reasonable certainty that it was presented to and proceeds from a court of competent jurisdiction in the case; that the place where it was found was within its jurisdiction; and lastly, that it was found upon the oaths of at least 12 jurors, who must further appear to have been of the county or other limits of the court's jurisdiction. The insertion of the jurors' names is not necessary. The indictment must be certain as to the name of the accused, and should repeat it with every

distinct allegation. In general a mistake in the name is fatal, though a mere misspelling of it, if the sound be rendered aright, may not vitiate the indictment. If several joined in the commission of the offence, as in assault or robbery, all may be joined in the bill, or each may be indicted separately. Yet when the crime is in its nature distinct and individual, as perjury or the utterance of blasphemous or seditious words, there can be no joinder, though several were guilty of the same offence. The time and place of every material fact must be distinctly averred. Generally, however, it is not necessary to prove the commission of the offence at the precise place and time laid. It is sufficient if it appear to have been committed within the jurisdiction of the court, and on any day previous to the finding of the bill, if that fall within the period during which the offence may be prosecuted. But if the time or place is an essential element of the crime, a variance in either respect between the charge and the proof is fatal. If it be necessary to cite written instruments, their dates must be truly stated. The date is also material when a period for preferring indictments is prescribed by law, or when statutes of limitations are involved. In the statement of the offence, the indictment must recite explicitly the facts which constitute the alleged crime, and not merely their supposed legal bearing. It is the simple office of the bill to exhibit the facts. If there be sufficient to constitute the crime charged, that will be judicially recognized by the court as their legal consequence. A particular offence must be alleged. To charge the defendant with one of two offences disjunctively, as "forged or caused to be forged," is insufficient; and so it is to describe him as a general offender, as "common thief" or "common slanderer." Yet one may be indicted as a "common barretor," or as a "keeper of a common bawdy house," for in these cases the habitual character makes the particular offence.—In the description of some crimes certain technical words and terms must be employed; thus, "traitorously" in indictments for treason, and "feloniously" in all charges of felony; "kill and murder" in charging murder, and "took and carried away" in a case of simple larceny. In indictments under statutes it is sufficient to describe the offence in the words of the statute. The indictment must conclude in the prescribed form, where that is given by the state constitution. It is generally in the words, "against the peace and dignity" of the state or commonwealth.

INDIES, East. See EAST INDIES, and INDIA.

INDIES, West. See ANTILLES, and WEST INDIES.

INDIGO, a vegetable dyestuff, known to the ancients by the name of *indicum*, from its being brought into Europe from India. The same name appears to have been applied to India ink also, but in this case usually qualified by the epithet *nigrum*. So little was

known of the real nature of this substance, which for centuries had been employed in painting and dyeing, that as late as the year 1705 it was spoken of as a mineral in letters patent issued in Halberstadt, Germany. The use of indigo in dyeing was probably introduced into Italy as early as the 11th century. With the establishment of direct trade with India by sea, supplies of it were more easily obtained, and after the discovery of America a similar product was brought from the new world. Francisco Hernandez speaks of it as in use by the Mexicans, the pigment being called *mohuitli* and *tleuohuilli*, signifying the same as the Latin name for it, *cæruleum*. In the beginning of the 17th century the importations of indigo from the East Indies into Holland assumed no little importance. In 1631 there was brought by seven vessels 333,545 lbs., estimated to be worth \$500,000. Its introduction caused great complaint by the Germans on account of its superseding the indigenous

Indigofera tinctoria.

woad. Its use was prohibited by the diet in 1577, and it was denounced under the name of the devil's dye as a pernicious, deceitful, corrosive substance. The people of Nuremberg, who cultivated woad, enacted a law compelling the dyers to take an oath annually not to use indigo, and this they were still obliged to do long after the dye was in universal use. By the French government the use of indigo was forbidden in the province of Languedoc in 1598, and the law was long enforced. A similar outcry was raised against it in England in the reign of Elizabeth, and in 1581 it was condemned by act of parliament, and persons were authorized to search for and destroy it and logwood also in any dye house. This law remained in force nearly a century.—Indigo is a product of numerous plants belonging to the order *leguminosæ*, and indigenous to the tropical regions of Asia, Africa, and America. The genus *indigofera* contains about 220 spe-

cies, several of which yield the indigo of commerce. *I. tinctoria* is the one most cultivated in the East, and *I. anil* is the most employed in America; these two species are found naturalized in the southern states as remains of former cultivation. *I. Caroliniana* and *I. leptosepala* are indigenous species from North Carolina southward, and are said to be useful in domestic dyeing. Indigo is also yielded by a few other genera of *leguminosæ*. These plants contain the coloring principle in their leaves, in the form of a colorless substance which is brought out and rendered apparent by its oxidation as the leaves dry, or is developed by submitting green leaves to a process of fermentation and oxidation. The *I. tinctoria* is cultivated both in the East and West Indies. It is a shrub, though sometimes cultivated as an annual, 4 to 6 ft. high, with pinnate leaves and rose-colored papilionaceous flowers. The seeds are sown in March and April in a light soil, and harrowed in. Weeds are removed, but after a few showers the plants cover the ground, keeping out all other vegetation. Before they have reached their full height the plants should be cut, always early in the morning, and carried the same day to the factory. Here they are laid at once in a stone cistern 20 ft. square and 3 ft. deep. Hurdles are placed upon them, and heavy beams are laid across these and secured to the sides of the vat, the object being to keep the plants down when they swell. Water is then admitted so as to cover the plants. Fermentation soon commences, and may be allowed to go on for 10 to 14 hours, according to the condition of the plants, the temperature, and the weather. The liquor is in commotion as if boiling; frothy bubbles rise to the surface, and their color, first white, becomes grayish blue and then deep purple, and finally a copper-colored scum covers the surface. When the agitation subsides the liquor is drawn off into a lower vat; and the beams and hurdles being removed from the upper one, the steeped plants are taken out to be dried for fuel, and the vat is prepared for another charge. Several men enter the lower cistern and beat up the liquid with their hands or with paddles till the coloring matter begins to appear in small atoms. This may require an hour and a half. The appearance of a precipitate as fine as small sand, leaving the water clear, indicates favorable progress; the beating is then discontinued, and the vat is left a few hours for the indigo to subside. The liquor is then run off from an upper vent, and after this the indigo from a lower one; or the latter is sometimes left in part as the water is drained away, and is then gathered up by a person entering the vat. Lime and gum have been employed to hasten the precipitation, but their use is considered objectionable from their supposed injurious effect upon the quality of the indigo. The pulpy precipitate is next freed by standing in another cistern from more of the water mixed

with it, and is then passed through a strainer into a boiler, in which it is heated to ebullition, and by some kept boiling for five or six hours. Being freed from scum, it is drawn off into a vat, from which, after subsiding, more water is taken off the top, and the rest is removed to the dripping vat, a wooden case having its floor perforated with holes and covered with a woollen cloth. The liquor passes through this filter, and the operation is completed by subjecting the residue to the action of a press, forming it into a cake, which is cut by a wire into 64 square blocks. These are laid out upon hurdles to dry in the shade, and left for several days or weeks in the drying house before packing. By the other method the leaves separated from the stems are dried in the sun, and then stored. When a large quantity is collected they are infused with six times their bulk of water, and stirred for two hours till the leaves all sink. The liquor is then drawn off, beaten, and further treated as in the process already described.—The Asiatic commercial indigo is brought from the several ports of India, and from Java and Manila. It differs much in quality and in shades of color. The best Bengal indigo shipped from Calcutta is the superfine or light blue, in cubical cakes, so light as to float upon water, friable, soft, of clean fracture, and of beautiful copper color when rubbed with the nail. Other qualities are of shades of violet, red, and copper color. The African indigoes from Egypt and Senegal are fine blues, but generally contaminated with earthy matters. The best American qualities, as some of those from Guatemala and Carácas, are equal to the best Bengal. These countries furnish a considerable portion of the indigo of commerce. The southern portion of the United States exported annually in the early part of the present century about 134,000 lbs. of indigo, worth 62 cts. per lb. Up to the time of the civil war it was cultivated in Florida and South Carolina, where the yield was about 60 lbs. to the acre, and the crop required attention from July to October. In 1871 the United States imported 1,994,752 lbs., about equal portions coming from Bengal and from Central and South America. A very superior quality is now produced at Bogotá.—The coloring matter of indigo, called pure indigo or indigo blue, usually constitutes nearly 50 per cent. of the commercial article, which may be obtained by dissolving out what is soluble in boiling water, then that which alcohol will remove, and finally what hydrochloric acid will take up. The residue is pure indigo and any silica that may be present. Various methods are adopted by different chemists for determining more exactly the proportions of indigo blue in samples of indigo. Some reduce the coloring matter by deoxidizing agents to indigo white, which is supposed to have been its original condition in the plants, and then precipitating and collecting this. Thus Dr. Dana dissolves the indigo by boiling in caustic soda with cau-

tious addition of protochloride of tin; the insoluble portion being then separated, bichromate of potash recovers and throws down the indigo blue, which when washed with hydrochloric acid is collected and weighed. Others adopt the plan of first taking up impurities by a succession of appropriate solvents; these impurities are chiefly resinous and gummy matters. The pure indigo has also been obtained by another process dependent on its property of volatilizing at the temperature of about 550° F., and condensing in needle-shaped and prismatic crystals. The operation is hastened by mixing the indigo with water and twice its weight of plaster of Paris to a paste, which is spread on an iron plate. Heated over a spirit lamp, the steam and vapor of indigo separate together, and the latter collects in beautiful velvety crystals, upon the surface of the mass. The pure substance melts nearly at the temperature at which it sublimes, and is also charred and decomposed at about the same. It also ignites and burns with a bright flame, giving off much smoke. The crystals have a beautiful and intense copper color, and when in thin plates they present by transmitted light a splendid blue. Their composition is represented by the formula $C_{16}H_{10}N_2O_2$. The substance resists in a remarkable degree the action of the ordinary solvents (sulphuric acid excepted), unless it be first deoxidized, when it readily dissolves in alkalies. The conversion into colorless indigo, though called deoxidation, appears to be rather an accession of two atoms of hydrogen, which, according to Liebig, unite with one of the oxygen present, giving to the body the composition of a hydrate, having the formula $C_{16}H_{10}N_2O + H_2O$ or $C_{16}H_{12}N_2O_2$; the indigo blue in this case being an oxide of the same body, $C_{16}H_{10}N_2O$. The facility with which the change is effected, and the readiness with which the indigo regains its blue color and insolubility by exposure to the air, admirably adapt the substance for use as a dye. It is applied in the solvent state to the fabric steeped in the liquid; and when the cloth is exposed to the air, the insoluble substance is developed with its characteristic color and fixed in the fibres.—Sulphuric acid dissolves indigo blue without changing its color to red, the usual action of acids upon vegetable blues; and when the substance is digested for three days with 15 parts of concentrated sulphuric acid, a deep blue pasty mass is obtained, which dissolves completely in water, and under the name of sulphindyllic acid, or more properly hyposulphoindigotic acid, is often used in dyeing, and also in the manufacture of the blue inks. Many other beautiful and highly interesting bodies result from this chemical change, and still more from the oxidation of indigo blue; and still another series from its treatment with the alkalies. These have received much attention from eminent chemists, and are particularly treated in Dumas's *Traité de chimie appliquée aux arts*, vol. viii., in Brande's

"Manual of Chemistry," and in Muspratt's "Chemistry."—Indigo has been somewhat used in medicine, but is not at present recognized as a remedy of value. It sometimes produces nausea and vomiting. It colors the stools bluish black, and also passes into the urine. Indican has occasionally been found in the urine when no indigo has been taken. The dose is from 30 to 120 grains.

INDIGO BIRD (*Cyanospiza cyanea*, Baird), a North American finch, of a blue color, tinged with ultramarine on the head, throat, and middle of breast, and elsewhere with verdigris green; lores and angle of chin velvet black, and wing feathers brown edged with bluish brown. The length is about $5\frac{1}{2}$ in., and the extent of wings $7\frac{1}{2}$; the female is smaller, and yellowish brown with the wings darker. It is found in the eastern United States, as far west as the Missouri, and south to Guatemala; it ar-

Indigo Bird (*Cyanospiza cyanea*).—1. Male. 2. Female.

rives in the southern states from Mexico and Central America about the middle of April with the painted finch (*C. ciris*), and like this is caught in traps for sale. It prefers open places on the edges of woods; perched on the top of a high tree, it delights to sing its clear and sweetly modulated strain, consisting of eight or ten notes. Though less handsome than the painted finch, its shape is elegant and compact, and its manners very lively, so that it is in request as a cage bird. The nest is made among the rankest grass, and the eggs, four to six, are blue, with one or two purple spots on the larger end. They migrate southward in the autumn. The food is small seeds and insects.

IDIUM, a rare metal discovered in 1863 by Professors Reich and Richter of Freiberg, Saxony, by means of spectrum analysis, and so named from two indigo-colored lines in the more refrangible part of the spectrum. It was originally detected in the zinc blende of Freiberg, and has since been found by Böttger in the flue dust of the zinc furnaces at Goslar, by

Winkler in the black blende (christophite) of Saxony, by Hoppe-Seyler in the wolfram of Zinnwald, by Köchler in the blende of Schönfeld, and by Cornwall in the blende of Maine. Indium is more easily prepared from crude metallic zinc than from any of the original ores. The metallic sponge remaining after treatment of the impure zinc with dilute sulphuric acid, or obtained as a residue in the cells of galvanic batteries, is acted upon by strong nitric acid, the excess of which is evaporated and the oxide of tin and sulphate of lead filtered off; the filtrate is treated with ammonia, which precipitates the oxide of indium, and after drying this oxide can be reduced to the metallic state by cyanide of potassium or by hydrogen gas. Indium is a brilliant, silver-white metal, destitute of crystalline structure, very soft and delicate, and easily scratched by the finger nail. It is permanent in the air, and retains its metallic lustre even in moist air and carbonic acid. The specific gravity depends upon the method of its preparation, and varies from 7.11 to 7.42. The melting point is 176° C. Although more easily fused, it is less easily volatilized than zinc or cadmium. At a bright red heat the metal burns with a violet flame and brown smoke. It is slowly dissolved by dilute sulphuric and hydrochloric acid, with evolution of hydrogen; quickly by strong hydrochloric acid. The atomic weight is given by Schrötter as 75.61, by Bunsen as 113.4. Indium monoxide has the formula InO ; its sulphide is yellow, and closely resembles sulphide of cadmium. The chloride is produced by passing chlorine gas over the oxide mixed with coal, or over the metal; it can be easily sublimed to beautiful, brilliant, crystalline scales, and is highly deliquescent. Numerous salts of indium have been prepared, but none of them possess any particular value in medicine or the arts.

INDO-CHINA, or the **Indo-Chinese Peninsula**, the name given to the southeastern portion of Asia, bounded N. by Thibet and China, E. by the gulf of Tonquin and the China sea, S. and S. W. by the China sea, the gulf of Siam, the strait of Malacca, the gulf of Martaban, and the bay of Bengal, and N. W. by Hindostan; area, about 850,000 sq. m.; pop. about 25,000,000. It is also designated as Further India, and as India beyond the Ganges. Andaman, Mergui, Nicobar, Prince of Wales, and other adjacent islands and groups belong to it. The political divisions of this region are: British Burmah, or Aracan, Pegu, and Tenasserim, comprising the W. coast and frontier land; Siam, in the centre, extending to the gulf of Siam, and including the Malay peninsula; Cambodia, and French or Lower Cochin China, on the S. extremity; Anam, including Tonquin and Cochin China, on the east; and Burmah in the northwest, surrounded by British Burmah, Siam, Anam, China, and Thibet. The Laos race, numbering about 1,500,000, occupy a large portion of the interior of Indo-China

between Siam and Anam, in the dominions of China, Siam, Anam, and Burmah. (See the separate articles on the political divisions.)

INDO-CHINESE RACES AND LANGUAGES. The nations belonging to this division of the Mongolian race inhabit southeastern Asia, and speak monosyllabic languages. They may be subdivided into seven groups: the Thibetan and Himalayan or Bhotiya races; the Burmese and Lohita races; the aboriginal races of the Indo-Chinese peninsula; the Thai races; the Anamites; the aborigines of China; and the Chinese. Several ethnologists and linguists prefer various other classifications; but, as has been observed by Prof. Whitney and other authorities, one cannot well resist the conviction that these races, which speak the only languages known of a monosyllabic type, and which are clustered together in one corner of a single continent, all belong to the same family of mankind, and that the dialectic differences, however great, are the result of discordant historic growth.—The Thibetans inhabit Thibet proper, or the elevated region north of the Himalaya mountains. Several races in those mountains, between the Indus and the Brahmapootra, also speak a language related to the Thibetan tongue. They have all remained in a low stage of civilization, retain the superstitions of the ancient north Asiatic races and the custom of polyandry, and have kept aloof from Buddhism. As that religion was carried into Thibet about the 7th century of our era, it is supposed that these tribes separated from the kindred races in Thibet in the 6th century or earlier. The races belonging to this division are the Mishnu, Bors, Dophla, and Aka, between the Brahmapootra and the Chumulari mountains; the Lepchas and Bhotans, in the central region of the watershed of the Teesta; the Kiranti and Limbu, in the region of the Coosey; the Newar and Murmi, between the Coosey and Gunduck; the Sunvar, Gurung, and Magar, in the territory of the river Gunduck; the Rongbo and Gurwhal, in the territory of the Surju river; and north of them the Kohli, Kakka, Bamba, Gakar, Khatir, Avan, and Ganjuh. The lower region is inhabited by the Mecha, Kichak, Tharu, Denwar, Bok-sar, Hayu, Chepang, Kusunda, Durro, and Bramho tribes.—The Burmese inhabit the W. portion of the Indo-Chinese peninsula, where they conquered the aborigines and formed a mighty empire. They are closely related to the inhabitants of Aracan on the coast of the bay of Bengal. With these two races are connected a number of wild tribes, generally designated collectively as Lohita, which is another name for the Brahmapootra; their relation to the Burmese is similar to that of the Bhotiya or Himalaya races to the Thibetans. Each of these numerous tribes speaks a peculiar dialect. The most important of them are the Bodos, Borros, or Kacharis, who were formerly called Rangtsa, and who, according to their tradition, emigrated into their

present country from some place N. of Assam. They were the conquerors of the ancient empire of Kamarupa, and the founders of the dynasty of Ha-tsung-tsa. The Garrows live W. of the Cossyah mountains; the Changlos inhabit the upper valley of the Brahmapoetra; the Miris the hilly country N. of Luckimpoor; the Abors the mountainous region S. of the Himalaya; the Singphos the N. portion of the Burmese empire; and the Mikirs the district of Nowgong in central Assam. To this division also belong the numerous Naga tribes, or Kwaphis according to their own designation; they inhabit the regions W. of the river Kopili, E. of the mountains which separate Assam from the Bor-Khamti country, and N. of the valley of Assam. The Khyeng inhabit the Youmadoung range which separates Aracan from the valley of the Irrawaddy. The Karens live in the mountains of Aracan, in Pegu, and in southern Burmah; also in the valleys of the Irrawaddy and the Salwen. The Sabaing who dwell in the valley of Sittoung, near the city of Toungoo, also belong to this group.—The aborigines of the Indo-Chinese peninsula are probably all the tribes inhabiting principally its mountainous districts and river embouchures. They were driven back to these regions by the Anam and Thai races who immigrated and settled in the valleys. They are barbarous nations, on whom neither Buddhism nor Chinese civilization has produced any impression. Among them may be mentioned the Mons, in the delta of the Irrawaddy, called Talaing by the Burmese; the Khomens or inhabitants of Cambodia, dwelling near the Mekong; the Tsiampas, S. of the Anamese, who call them Lau; the Kwantos, who are the real aborigines of Tonquin and live in the mountains on the frontier of China; and the Mois, W. of Cochin China. Several travellers have described the last as being essentially of a negro type.—The Thai is the dominant race of the Indo-Chinese peninsula. The Siamese are the Thais proper, and the most numerous. The Burmese, Chinese, and Anamese give them the name of Shian, whence comes the Portuguese *Sião*, and our Siam. The Laos inhabit the interior and the north of the peninsula; they are subdivided into white Laos (*Lau-pang-kah*) and black Laos (*Lau-pang-dun*). Other Thai races are the Ahoms, Khamtis, and Cossyahs. The Anamese inhabit Tonquin and Cochin China; they are not as closely related to their western neighbors as to the Chinese.—Several uncivilized races, which differ from the Chinese proper in language, religion, and manners, seem to be, and are called, the aborigines of China. They adhere to the Shamanism of the people of High Asia. The most important races among them are the Sifan, the Miautze, and the Lolo. The Sifans inhabit the mountainous regions W. of the Chinese provinces Shensi and Szechuen on the upper course of the tributaries of the Hoang-ho and Yangtse-kiang.

They are mentioned in the annals of China from A. D. 634, and are at present tributary to the Chinese. They lead a nomadic life, raise sheep, and live in tents. The Miautze are scattered over portions of several provinces, especially in Szechuen, Kweichow, Hunan, Hupeh, Yunnan, Kwangsi, and on the frontier land of Kwangtung. It is supposed that the inhabitants of Hainan are related to them. The Lolos are the aborigines of Yunnan in S. China; they are good miners and skilled forgers of weapons. In the ancient annals of China two barbaric races are mentioned, the Man and the Y; but it has not been determined whether they were distinct races, or related to those already described.—The Indo-Chinese languages, if we include those spoken in Thibet and China, comprise all the monosyllabic languages known. The language now spoken in Cochin China is to be considered, according to Max Müller, as a dialect of Chinese, at least as much as Norman French was a dialect of French. The Chinese was grafted on the Anamitic, the native language of Cochin China; yet few Chinese scholars would recognize their language in that of Cochin China. For instance, it is one of the most characteristic features of the literary Chinese, the dialect of Nankin, or the idiom of the mandarins, that every syllable ends in a vowel, either pure or nasal. In Cochin-Chinese, on the contrary, we find words ending in *k*, *t*, *p*; thus ten is *thap*, at Canton *chap*, instead of the Chinese *tschi*. In Chinese, Anamitic, Burmese, Siamese, and all other monosyllabic tongues, there are six or eight musical accents or modulations by which the different meanings of the same monosyllabic root are kept distinct. The Chinese has no more than about 450 distinct sounds, and with them it expresses between 40,000 and 50,000 words or meanings. Thus, in Anamitic, *ba* pronounced with the grave accent means either a lady or an ancestor; pronounced with the sharp accent, the favorite of a prince; with the semi-grave accent, what has been thrown away; with the grave circumflex, what is left of a fruit after it has been squeezed; with no accent, three; with the ascending or interrogative accent, a box on the ear. Thus the series *Ba*, *bà*, *bá*, *bá* means, if properly pronounced, "Three ladies gave a box on the ear to the favorite of the prince." The difference between the speech of the Siamese and their neighbors the Burmese is very marked. The Burmese use an excessive number of triple consonants, *mlw* and similar combinations; but in nothing is the difference more noticeable than in the frequent use by the Burmese of the *th* sound, uttered with a strong guttural breathing, where the Siamese use *s*. The two alphabets also are very dissimilar in form, the Burmese using a round character derived from Ceylon, while the Siamese have a comparatively square character supposed to be derived from the ancient Cambodian letters still used for their sacred books, and generally for the

Pali language, and which in turn appears to be a form of the Devanagari. The Laos in N. Siam speak a mixed dialect of which Siamese is the principal component, and use the Burmese alphabet.—See De Carné's "Travels in Indo-China and the Chinese Empire" (London, 1872), and Vincent's "Land of the White Elephant" (London, 1874).

INDO-EUROPEAN RACES AND LANGUAGES. See **ARYAN RACE AND LANGUAGE**, and **GERMANIC RACES AND LANGUAGES**.

INDORE. I. A native state of India, constituting the dominions of the Mahratta chief, the maharajah Holkar, and consisting of several isolated tracts scattered over a large part of central India; aggregate area, 8,318 sq. m.; pop. about 850,000. It is bounded S. and W. by Dhar and the territory of the Bombay presidency, and N. and E. by Sindia and the rajahship of Dewass. It is traversed E. and W. by the Vindhya mountains, and the Satpoora range runs in the same direction along its S. border. The valley between these ridges is watered by the Nerbudda flowing W. The N. part of this tract, and most of the other portions of Holkar's territory, belong to the great table land of Malwah. The N. districts are watered by the Chumbul and its feeders. The soil is generally fertile, producing wheat and other grain, opium, pulse, sugar cane, cotton, and tobacco. The inhabitants comprise Mahrattas, the dominant race, Bheels, Gonds, and a few Mohammedans. The Bheels are supposed to be the aborigines. The Gonds or Khoonds are numerous in all this part of India, and have given their name to the region of Gondwana, which extends S. from Indore. (See **BHEELS**, **GONDS**, and **MAHRATTAS**.) Like all states in subsidiary alliance with the British government, Indore is occupied by British forces, which protect it against invasion, and maintain the authority of the maharajah. The British government receives in return an annual subsidy, which may be paid, if preferred, by cession of territory, and reserves the right of interference in cases of bad government on the part of the native chief.—In 1733 the town and district of Indore were given by the peishwa to Mulhar Row (or Rao) Holkar, a Mahratta leader, born a shepherd, who had risen by his courage and talents as a soldier. He died in 1766, and was succeeded by a grandson, who soon died insane, leaving the sovereignty to his mother, Alia Bacc, who retained it for 30 years. In 1797 the commander of her forces, Tookajee Holkar, died, and his illegitimate son, Jeswunt Row Holkar, seized the government. He was expelled by the Sindia family, but reinstated himself in 1802. He inaugurated an extensive system of plunder, for which the British authorities made war on him. He advanced on Delhi at the head of 60,000 horse, but was defeated by Lord Lake in two engagements. In 1805 he entered the Punjab with a new army, but was closely followed by Lake, and in December concluded a treaty which left him in possession of nearly

all his dominions. He died insane in 1811, and his mistress Toolsee Bye acted as regent for Mulhar Row Holkar, his natural son by another woman, until she was murdered in 1817, and young Mulhar was seized by the army, which, ostensibly under his command, began hostilities against the British. After a decisive battle at Mahidpoor, Dec. 21, 1817, a treaty was signed in January, 1818, by which the Mahrattas ceded a large part of their territory and retained the rest under British protection. Mulhar Row died in 1833; his successor, Martund Row, was dethroned to make room for Hurree Row, an imbecile prince, who left the government to his adopted son Kumdee; and when the last named died without heirs, the East India company assumed the right of nominating as his successor Mulkerjee Row Holkar, who took the reins of government in February, 1852. At the outbreak of the mutiny in 1857 he attempted to take the field for the British; but many of his troops deserted, and the remainder held him a prisoner in his palace and massacred a large number of Europeans. **II.** A town, capital of the state, situated in a plain on the left bank of the small river Kutki, 13 m. N. W. of the British military station of Mhow, and 317 m. N. E. of Bombay; pop. about 15,000. It is an ill-built place, contains a few mosques, several Hindoo temples, and the palace of Holkar, and has no handsome edifices except the houses of the English inhabitants. The palace, of granite, which fronts on an open place, is over 300 ft. square and six stories high, enclosing a court surrounded by pillars of black wood. Its style of architecture is impure Saracenic. The town is walled, but its defences are of no great strength. There is a British resident here. The present town is comparatively modern, the ancient Indore being on the opposite side of the river. Indore was plundered in 1801 by Sindia, and in 1804 it was occupied by a British force under Col. Murray, who surrendered it on the conclusion of peace in the following year.

INDORSEMENT, or Endorsement. See **EXCHANGE**, **PROMISSORY NOTE**, and **NEGOTIABLE PAPER**.

INDRE, a central department of France, formed chiefly from the old province of Berry, bordering on Loir-et-Cher, Cher, Creuse, Haute-Vienne, Vienne, and Indre-et-Loire; area, 2,624 sq. m.; pop. in 1872, 277,693. The surface is mostly level, and presents three marked and distinct divisions: Bois Chaud, where the farms are small, and the scenery varied from the number of its hedges, hedge rows, and woods; Champagne, a flat treeless region, without hedge or shrubby enclosure of any kind; and La Brenne, a low district, covered in part with shallow ponds, the mephitic exhalations of which are very unhealthy. The principal rivers are the Indre, Creuse, Claise, Arnon, and Fouzon. The Indre rises in the department of Cher, and joins the Loire after a N. W. and W. course of about 130 m.,

for the last 44 of which it is navigable. The climate, except in the district of La Brenne, is mild and healthful. The soil is rather light and gravelly, but not ill adapted for the growth of cereals. Nearly two thirds of the whole area is arable. Grain is raised for exportation; next in importance are the crops of hemp and flax. The wine produced is not highly esteemed. There are large numbers of sheep with a very fine quality of wool. Iron mines are worked, and there are a few quarries of marble, millstones, granite, and mica. Linen cloths, hosiery, scythes, paper, porcelain, and earthenware are the principal manufactures. The department is divided into the arrondissements of Châteauroux, Le Blanc, Issoudun, and La Châtre. Capital, Châteauroux.

INDRE-ET-LOIRE, a central department of France, in the old province of Touraine, bordering on Sarthe, Loir-et-Cher, Indre, Vienne, and Maine-et-Loire; area, 2,361 sq. m.; pop. in 1872, 317,027. It is named from the rivers Indre and Loire, which unite within its limits. The Vienne and the Creuse water it in the south. In the N. districts are several arid wastes, and all over the department many extensive forests, the largest of which are those of Amboise, Loches, and Chinon. The climate is remarkable for its mildness and salubrity. The soil is in general extremely fertile. The land on both sides of the Loire is called the garden of France, and consists of a light but deep vegetable loam. Grain, hemp, flax, anise, and coriander are grown on a large scale. Fruit is very abundant, and the Tours prunes are largely exported. Much wine is made, some of which bears a high reputation. Bees and silkworms are carefully tended; game and fish are abundant. The chief industrial products are bar iron, hardware, powder, woollen cloth, silk, leather, paper, and pottery. The department is divided into the arrondissements of Tours, Chinon, and Loches. Capital, Tours.

INDRI. See LEMUR.

INDULGENCE (Lat. *indulgere*, to yield, to grant), in the Roman Catholic church, the remission of the temporal penalty to be undergone by the sinner, after his sin has been forgiven in confession. The term originated in the discipline of the early church, when notorious sinners were sentenced, after they had been absolved in confession, to periods of public penance sometimes extending to the hour of death. The sincere sorrow of the offenders, the intercession of those who were imprisoned or about to suffer death for the faith, and occasionally even the prayers of the civil magistrates, induced the bishops to be indulgent to the penitents, by granting them a remission of the imposed canonical penance, or by relaxing its rigor. The use of public penances passed away with that of public confession, and was replaced both in the eastern and western churches by good works, private austerities, and devotional exercises. When Christianity spread among the northern nations of

Europe, the canonical penances were found to be inapplicable to their condition. Their pagan jurisprudence had accustomed them to pecuniary mulcts, so that persons guilty of theft or murder could purchase exemption, and compound with the injured parties or their relatives, by paying a stipulated fine. This system was applied by the church to penitential atonements; and the money thus contributed was employed in almsgiving, or for the redemption of captives, the freeing of slaves, or the expenses of public worship. The directions drawn up by Theodore of Canterbury and Egbert of York in the 8th century, and by Halitgar of Cambrai in the 9th, were framed for the purpose of administering penance in conformity with these national customs. But this substitution of pecuniary fines gave rise to serious misapprehensions and gross abuses. It was easy for the unlettered multitude to confound the remission of the canonical penalty thus obtained for money with the purchase of pardon for sin. Many councils and ecclesiastical writers of these times either denounced the practice altogether, or urged upon the clergy the duty of instructing the people on the true nature of penitential satisfaction. The synod of Cloveshoo or Abingdon in 742 stigmatized the prevalent error that almsgiving releases the sinner from the more stringent kinds of penance; and in 813 the second council of Châlons uttered a similar warning. In 1095 the council of Clermont, by the authority of Pope Urban II., offered a "plenary indulgence" to all who took the cross for the purpose of delivering Jerusalem. It was enacted that all who, having confessed their sins with true repentance, might engage in the expedition, should be exempted, in consequence of the labor and dangers to which they voluntarily exposed themselves, from the canonical penances to which they were otherwise liable. The council of Lyons in 1274 extended the same indulgence to all who, unable to join the crusade in person, should by voluntary donations contribute to its success. From that period indulgences began to be multiplied, and as often as money was required for any object connected with the interests of the church, they were offered to the people. Out of this practice grew abuses of two kinds. The money thus obtained was frequently diverted from its original destination; and the office of collecting it being committed to inferior agents, secular as well as ecclesiastical, it became their interest, as they received a percentage on the amount, to exaggerate the advantages of the indulgence, and to impose upon the credulity and simplicity of the people. Severe constitutions were enacted by several popes to prevent such abuses, and to punish the rapacity and impiety of the collectors; but these laws were not enforced, and fell into disuse. Besides, during the great western schism the rival pretenders to the papacy lavished indulgences among their supporters. This brought both the

indulgence and the authority which dispensed it into discredit. The crisis came when Julius II. proposed the erection of the new basilica of St. Peter's on the Vatican hill, and published an indulgence in Poland and France in favor of all who should help defray its cost. His successor, Leo X., added to this object a crusade against the Turks, and extended the indulgence to the northern provinces of Germany. The papal commission for this purpose was issued to the archbishop of Magdeburg, who delegated it to the Dominicans, among whom was the notorious Tetzl. They spread themselves rapidly over Saxony, and, according to Luther, offered indulgences in the streets, markets, and taverns, teaching that every contributor, if he paid on his own account, infallibly opened to himself the gates of heaven; if on account of the dead, instantly liberated a soul from purgatory. These abuses were subsequently condemned by the council of Trent, and measures were prescribed for suppressing them or preventing their recurrence in each diocese. Since that period, though no such general abuses have been noticed by historians, yet in many Roman Catholic countries indulgences have continued to be published in forms which give great offence, especially to Protestants.—The expressions used, and the local customs relating to indulgences, can only be rightly understood from a clear statement of the doctrine of the Roman Catholic church on this subject. She teaches that by sacramental absolution the guilt of sin (*reatus culpe*) committed after baptism is taken away, together with the eternal punishment it deserves, by virtue of Christ's sufferings; but that the pardoned sinner remains liable to the *reatus pænæ*, or to a temporal penalty to be paid in this life or the next. This penalty is not to be confounded with the "canonical penances" of the primitive church. It is held by Catholic theologians that St. Paul showed indulgence to the incestuous Corinthian before the institution of the system of canonical penances. These were established gradually by local usage in the East and West, without the authority of any general ecclesiastical law; and the penitential canons which regulated the application of such penances varied, like the usage itself, in different countries. As this whole system had been introduced by custom, so it fell into disuse without ever having been repealed by any general council. The church, meanwhile, never ceased to exact of the penitent the satisfaction due primarily to the divine law violated by his transgressions, and secondarily to the community scandalized and disturbed by them. So long as the penitential canons remained in vigor, the fulfilment of their prescriptions was held to be satisfactory before God and the church, releasing the penitent from the *reatus pænæ* both here and hereafter. A true satisfaction to the church meant a true satisfaction to God. In like manner, since the disuse of canonical penances, the fulfilment of those imposed by the church is to

be taken as the payment of what is due to God as well as to herself. Moreover, penitential works derive their worth and efficacy from their being performed in union with Christ's atonement. He and his sanctified members, whether in heaven, on earth, or in purgatory, form in the view of the church one moral person; and his Spirit imparts to the virtues and acts of his saints all the supernatural merit which they possess. Their merits added to his, like a finite quantity added to the infinite, do not increase the latter, but are only merged in it. These united merits of Christ the head and of all his true members constitute the property of regenerated humanity; they form a treasury committed to the guardianship of the church, of which she as his spouse is the dispenser. Out of this she sets apart a portion for her needy children, which they may make their own by the performance, in a state of grace, of specified good works, and with this acquired treasure purchase for themselves or for the dead perfect reconciliation and communion with God. The Christian who, by gaining an indulgence through the accomplishment of certain outward acts, thus becomes master of a portion of Christ's redeeming merits, purchases his own soul's perfect peace with "a price" which he presents to the divine justice through Christ; and if he offer the whole fruit for the release of a soul in purgatory, he does so through the church, *per modum suffragii*, as an intercessory offering, which God may or may not accept, but which the church assumes he actually does accept in ratification of her action. In both cases, when every prescribed condition for the gaining of an indulgence has been fulfilled, God remits in heaven what Christ's spouse remits upon earth. The nature and existence of this treasury of merits, its application, as here explained, to the living and the dead, and the ratification by God of the acts of the church relating to indulgences, are, without being defined as of faith, considered as *proxima fidei*. As the temporal satisfaction or penalty due by the sinner after sacramental absolution is a consequence of the sin itself, it has always been called sin in the style of the Roman chancery, and in the papal bulls which treat of indulgences and jubilees. Hence the phrase "full and complete remission of sins" is to be understood as meaning the full and complete remission of the temporal penalty secured by the fulfilment of the conditions prescribed for an indulgence, a necessary but tacit preliminary to which is sacramental absolution to the truly contrite. In no supposable case can indulgence be a pardon for the guilt of sin even to the most heart-stricken penitent, still less a prospective pardon of future sins, or a license for committing them. A plenary indulgence is the remission of the entire satisfaction due to God and subject to the power of the church. The indulgence of a jubilee differs from this, not in a fuller relaxation of penalty, but in the wider

absolving faculties granted on such an occasion to confessors. A partial indulgence, specifying any limited time, alludes to the forms of the old penitential canons, which enjoined for each sin a penance proportioned in rigor and duration to its gravity. The inscriptions to be found in Rome or elsewhere in Catholic churches on what are called privileged altars give much offence to Protestants, because the words denote that "these souls are delivered from purgatory." Benedict XIV. explains them by saying that "whenever a pope declares an altar to be privileged, he sets apart, each time the eucharistic sacrifice is offered on it for a departed soul, a sufficient portion of the church's treasure of merits to obtain from God, if it so pleaseth him, the release of that soul from purgatory." This explanation also applies to the indulgences attached to certain festivals, to privileged pilgrimages, to visiting certain churches, or to the performance of such devotions as the "way of the cross." All can be appropriated to the souls in purgatory in the way mentioned above.—The Scriptural grounds to which Roman Catholic theologians appeal in support of their doctrine of satisfaction and indulgences are: 1, for satisfaction, the examples of Adam, Moses, Aaron, and David, who, though pardoned, were subjected to most grievous temporal punishments; 2, for indulgences, the power of the keys bestowed on Peter (Matt. xvi. 19), and on the apostles collectively (Matt. xviii. 18), and their exercise in binding (1 Cor. v. 4) and in loosing or remitting (2 Cor. ii. 6). Moreover, they contend, the doctrine of the church in this matter rests on tradition, which is interpreted by the perpetual usage of the church and the writings of the fathers.—See Wiseman's "Lectures on the Doctrines and Practices of the Catholic Church" (London, 1844; Baltimore, 1852); Bergier's *Dictionnaire de théologie*; Hirscher's *Lehre vom Ablass* (Tübingen, 1844); Neander's "History of Doctrines," vol. ii., 594, and "Church History," vol. iii.; and Hodge's "Systematic Theology," vol. iii.

INDUS, or **Sinde** (Sans. *Sindhv*, river; Pers. *Ab-Sind*), a river of Asia, rising on the N. side of the Himalaya, in Thibet, and discharging into the Arabian sea. Its three remotest feeders are the Senge-khabab ("sprung from the lion's mouth"), also called the Singi-choo ("lion stream"), the Lang-choo, and the Gartung-choo. All three have their sources N. of the Kailas range. The first named is the largest, and is considered the beginning of the Indus. It rises near the Kailas Parbat mountain, at an elevation of about 18,000 ft., about lat. 31° 10' N., lon. 81° 20' E., not more than 100 m. from the sources of the Sanpo, one of the principal feeders of the Brahmapootra, and of the Ganges. The Lang-choo flows into the Senge-khabab before the Gartung, and 50 m. further, flowing N. W., the river enters Ladakh. At Raldang, 100 m. from the confluence, it can still be crossed without

boats during the greater part of the summer. At Ranag, 9 m. below Raldang, it is passable for horses during the whole year. The extreme width of the river at this point, however, is remarkable. The water surface, measured in summer, was 2,158 ft. across, and left nearly in the middle of the river a bank 1,155 ft. wide entirely uncovered. It is presumed that in seasons of flood the Indus attains here a width of 3,313 ft. The depth is only 2 or 3 ft. The width of the river decreases very rapidly from this point, and about 450 m. from its source, near the city of Leh, it is reduced in the summer to 75 ft., with a depth of 8 ft. The valley of the Indus is here only 10,723 ft. high, the river having fallen nearly 5,300 ft., or at the rate of 12 ft. to the mile. Continuing its N. W. course through the valley S. of the Kailas range, 50 m. below the town of Kalatse it is still 75 ft. wide, but on only one third of the surface are signs of a steady flow; the remainder is either in a state of stagnation, or moves on very slowly. The river is however very deep in its main channels, measuring from 18 to 22 ft. About 55 m. below it receives the river Dras from Cashmere, and at Kiris, 47 m. further, it is joined on the right by the large river Shy-yok. At the mountain Mendok-kar, near Iskardoh, the chief town of Bulti, which the river reaches by a circuit of 50 m., it is no more than 7,255 ft. above the level of the sea. The name Senge-khabab disappears here, and the river begins to be known as the Ab-Sind, or Indus. About 60 m. below Iskardoh it changes its course suddenly from N. W. to S., and crosses the Himalaya a few miles above the E. end of the valley of Gilgit, from which it receives the river Yasan. It descends in a torrent to Bunji, a town 20 m. further on and only 4,870 ft. above the sea. A few miles below this it leaves the territory of Bulti and enters that of Kafiristan, through which it flows for nearly 170 m. in a tortuous S. W. and S. course. The character of this portion of the river is almost totally unknown. It returns to the British territory at Derband, measuring in August nearly 300 ft. across, but without much depth. There are five fords between here and Attock, 60 m. below; they are at times somewhat treacherous, and it is related that at one of them, just above the influx of the Cabool, Runjeet Singh lost 7,000 men in trying to cross with his army. Although the Cabool is navigable for 40 m., the navigation of the Indus terminates just above its confluence. Attock is situated 1,049 ft. above the sea, or 9,674 ft. below Leh. The course of the river between these two cities is 470 m. long, which shows a fall of nearly 21 ft. to the mile over this distance, or of a little more than 16 ft. to the mile from the source. From Attock to the sea the Indus is 942 m. long. It moves at first impetuously through high cliffs of slate, which contract it to a width of 250 ft., but render it 180 ft. deep. Near Kalabagh it enters a plain, takes up the Swan or

Soochan, and expands again to 1,500 ft. with an average depth of 60 ft. For the next 350 m., to Mittun Kote, the Indus takes a more southerly course, and separates into numerous arms, enclosing fertile islands, which are covered during the summer inundations with an immense sheet of water, extending over the level country of the E. bank. The main channel near Kaheree is 3,000 ft. wide and 12 ft. deep. Near Mittun Kote occurs the influx of the Punjnd, which carries into it the waters of the Jhylum, Chenaub, Ravee, Beas, and Sutlej, the five rivers of the Punjaub. The Indus swells here in its lowest stage to a width of 6,000 ft., and spreads in times of inundation over 20 m. on the W. and 10 or 12 m. on the E. side. A S. W. course of about 50 m. carries it into the arid, rainless, alluvial plain of Sinde, where extensive irrigation works have been constructed by the British government, and others are in progress. The river has so frequently changed its direction in flowing through this region that traces of ancient channels are very numerous, the main channel being now considerably further W. than formerly. Its banks are higher than the adjacent tracts, the surface of which slopes away from the river. This peculiarity is due to the silt brought down by the waters of the Indus and deposited in consequence of the decreased rapidity of its current in this nearly level country. These silt deposits are constantly forming new land in some localities and causing the river to break through its banks in others. From Mittun Kote to the sea the Indus flows over a distance of about 450 m. The East Narra is an ancient channel which separates from it near Soodaja, and extends S. E. through the desert of Thur; it is now supplied with water by canals connecting with the Indus. The West Narra branches off 18 m. below Roree, follows a tortuous S. course of about 160 m., forms the Mantchoor lake, and returns to the Indus near Sewan, 10 m. below. From this point the bed of the Indus is depressed 16 to 18 ft. below the adjacent lands. The Fulalee was originally a natural branch of the Indus on the E. side, returning to it about 16 m. below Hyderabad, the capital of Sinde, which is situated on the tract of land thus turned into an island. It has been converted into a main feeder for irrigation canals, S. and E. of that city. The delta of the Indus consists of numerous mouths between Hyderabad and the Arabian sea, and is about 100 m. long and 130 m. wide. The principal mouths are the Koree, the Seer, the Mooll or Maw, the Kookeewarree, the Kedywarree, the Rechel, the Pinteeancee, and the Pittee. The last is at present the widest and deepest, and always navigable; the Hujamree was the most important till 1838, when a sudden change in the channel rendered it entirely useless. The tide rises as far as Tattah, about 70 m. from the sea. The Indus is not navigable above Roree for vessels of more than 4 ft. draught. The entire length of the Indus is

about 2,000 m., and the area of its drainage basin is estimated at 312,000 sq. m. The rise of the river commences in May, and its waters subside in the latter part of August.—The 1,700 m. of railroad now in operation through Bombay, Sinde, and the Punjaub render the Indus less important as a means of transportation than as a means of irrigation in a sultry climate where rain seldom falls. The water is very unwholesome in the early part of the inundation, and at other times it is wholesome only if kept until the earthy and vegetable admixtures subside. Fish are abundant, and form a large portion of the sustenance of the population of the adjacent country. The alligators in it are long-snouted, of the kind called gavial. In the Vedic writings the Indus is called the king of rivers, and the Ganges as well as the other streams sing praises unto it. It is generally designated in them as Sindhu, "the river." The ancient inhabitants had no more definite name for their country bordering on the Indus than Sapta Sindhavas, "the seven rivers," counting with it the Cabool and the five chief streams of the Punjaub.

INDUSTRIAL EXHIBITIONS, public competitive displays of products for the encouragement of arts and manufactures, local, national, and international. The first industrial exhibition was held in Paris in 1798, and comprised chiefly specimens of French art manufactures, not contributed by their producers, but loaned by owners. This display led in the same year to a larger exhibition of all kinds of French manufactures, and the utility and success of the show prompted the more extended exhibitions, under the consulate of Napoleon, in 1801 and 1802. Thereafter exhibitions intended to be triennial, but interrupted by political causes or by war, were held from 1806 to 1849, the 11th and last exceeding all former ones. The first industrial exhibition in Great Britain was opened under royal patronage in London in 1828, but was not successful. Local exhibitions of the industry of manufacturing districts were held at Manchester in 1837, at Leeds in 1839, and at Birmingham in 1849. The royal society of Dublin began in 1829 a series of triennial exhibitions of Irish manufactures. Similar local exhibitions were held at Ghent in 1820, at Berlin in 1834, and at Vienna in 1835.—The first international exhibition at Paris in 1844 was so successful as to commend the scheme to the London society of arts, and in 1849 it matured a plan for a "world's fair," which was presented to the public by the president of the society, Prince Albert, who declared that the time had come to prepare for a great exhibition, "not merely national in its scope and benefits, but comprehensive of the whole world." A royal commission was issued Jan. 3, 1850, and the queen headed a subscription list with £1,000. A building popularly known as the "crystal palace" was erected in Hyde Park, from designs of Mr. (afterward Sir Joseph) Paxton, composed, excepting the floor-

ing and joists, wholly of glass and iron. It was 1,851 ft. long and 408 ft. wide, with an extension on the north side 936 ft. long and 48 ft. wide; height of central portion 64 ft., and of transept in the centre 108 ft.; entire area covered, about 19 acres. Portions of the palace were assigned to different countries and colonies according to the space required by each. The articles, excepting heavy machinery, were arranged in four principal sections, viz.: raw materials, machinery, manufactures, and fine arts. The paintings, however, were mostly assembled together; but some of the prominent pieces of sculpture were placed in different parts of the building, in order to attract special attention and to add to the beauty of the interior. The building was begun Sept. 6, 1850, completed Feb. 3, 1851, and cost £176,000. On May 1 the queen opened the exhibition, which continued till Oct. 11. The number of visitors was 6,170,000, an average of 43,500 a day, and the greatest number in one day (Oct. 7) was 109,915. No record was kept of the number of articles exhibited. There were more than 17,000 exhibitors. The prizes, including council and prize medals and honorable mentions, were 5,084, and the foreign exhibitors, occupying two fifths of the space, took three fifths of the honors. In machinery and in metal, glass, and porcelain manufactures, the British received the majority of prizes; in miscellaneous manufactures, textile fabrics, and fine arts, the foreign awards were one fifth more than the native; in raw materials the foreigners took nearly four times as many prizes as the natives (988 to 262). The popularity of the world's fair was largely due to the great number of gems, including the Koh-i-noor, and the works of art exhibited. The financial results were: receipts from subscriptions, £67,800; admissions, £425,000; refreshments, &c., £13,200; total, £506,000; expenditures, £330,000; the balance in favor of the commission was increased by interest and small receipts to £186,436. Those who were on the guarantee list were not called upon for their subscriptions. The final balance, with additional parliamentary grants, was applied to a scheme for the advancement of the fine arts and of practical science. The "crystal palace" was sold to a company, its reconstruction at Sydenham on an enlarged plan began Aug. 5, 1852, and it was reopened by the queen June 10, 1854. Since then it has been devoted to horticultural shows, monster concerts, and other public amusements.—There was a successful exhibition of Irish arts and manufactures at Cork in 1852, which led to the much larger international one at Dublin in 1853. This exhibition owed its origin to Mr. William Dargan, who advanced £80,000. The building, 425 ft. long, 100 ft. wide, and 105 ft. high, with adjoining smaller halls, cost £48,000. The exhibition was opened by the lord lieutenant May 12, and continued till Oct. 29. The value of the contents was £500,000, of which the fine arts rep-

resented £200,000. Up to that time no finer collection of pictures had been assembled in the kingdom. The exhibition was popular, and had 1,150,000 visitors; but it was not financially successful, and entailed a heavy loss on the projectors.—The New York world's fair of 1853 originated with a company incorporated in 1851. The city gave a lease of Reservoir square for five years rent free, upon the conditions that the building should be constructed of glass and iron, and that the admission fee should not be more than 50 cents. Congress also passed an act constituting the building a bonded warehouse, into which foreign goods might be brought free of duty. In March, 1852, the company issued shares to the amount of \$300,000, afterward increased to \$500,000 and readily subscribed. The building was in the form of a Greek cross, 365 ft. long each way, and 150 ft. wide, with a central dome 123 ft. high and 100 ft. in diameter; and on one side another building, 450 ft. long and 75 ft. wide, was erected for machinery. The president of the United States, Gen. Pierce, opened the exhibition July 14, and it continued 119 days. There were 4,800 exhibitors, more than one half of whom were foreigners. Among the many causes which operated against the success of the enterprise were the Dublin exhibition of the same year, the long delay in opening, the distance of the locality from the then centre of the city, and the inadequate means of access. The principal feature of the exhibition was the fine display of American machinery and agricultural implements. The financial results were: cost of building, \$540,000; fitting and furnishing, \$100,000; receipts from admissions, sale of catalogues, &c., \$340,000. The exhibition was reopened in 1854, and in that and the following year the company expended \$200,000, thus exhausting the capital, receipts, and two loans. The building was afterward leased to the American institute and used for its annual fairs, during the progress of one of which, on Oct. 15, 1858, it was burned with all its contents.—The Zollverein exhibition at Munich, from July 15 to Oct. 15, 1854, was held in a building of glass and iron, 800 ft. long, 280 ft. wide, and 87 ft. high, covering 250 sq. ft. of flooring, and costing \$450,000. From 33 Zollverein states there were 6,800 exhibitors of goods, worth about \$7,500,000; but the advent of cholera in the autumn and other causes reduced the number of visitors, and the Bavarian government was obliged to make up a deficiency of \$1,000,000.—The Paris international exhibition of 1855 was organized as follows: the government was to bear the cost and appoint the commission. A joint-stock company erected in the Champs Elysées a main building of glass, stone, and brick, 800 ft. long and 350 ft. wide, and other buildings for machinery, paintings, &c., were added. In the main building the goods were arranged by countries, and were classified nearly as in the London exhibition of 1851. But

besides the machinery and art buildings, it was found necessary to erect smaller buildings for carriages, agricultural implements, and cheap articles. Spaces in the open ground were also devoted to the exhibition of certain articles. The government guaranteed 4 per cent. on the outlay, and a share of the profits, if there were any; but as there were none, all the receipts for admissions went to the company. The cost of the buildings and other expenses amounted to about \$5,000,000. The emperor opened the exhibition May 15, and it continued till Nov. 15, during which time there were 4,533,464 visitors, one third fewer than to that of London in 1851, though the Paris exhibition was open on Sundays. There were 10,691 exhibitors from France and her colonies, and 10,108 from 53 foreign countries and 22 colonies. As a grand display the exhibition was very successful, and it was estimated that the money spent in Paris by foreign visitors compensated for the financial failure of the exhibition itself. In 1861 there were important exhibitions at Haarlem of the industries of Holland; at Nantes of the manufactures and fine arts of France and Algeria; and at Florence of Italian silk in all stages of its culture and of silk goods in every variety of manufacture.—The second London international exhibition, in 1862, started with a guarantee fund of £450,000, to which Prince Albert subscribed £10,000. A building of brick, glass, and iron, with flooring and galleries covering 1,400,000 sq. ft., was erected at South Kensington. This exhibition was intended by the society of arts to follow the great exhibition of 1851 as the second decennial in 1861; but the Italian war postponed it a year. The exhibition continued 177 days, during which there were 6,211,103 visitors; the largest number in one day (Oct. 30) was 67,891, and the daily average 36,329. There were in the industrial division 17,861 foreign exhibitors, who took 9,344 prizes, and 8,487 British and colonial, who received 4,071 prizes. The total expenditures were £460,000; receipts from admissions, &c., £448,000; the deficiency of £12,000 was wholly due to the great cost of the building, which was designed to be permanent, but was subsequently demolished, and the materials were used in the construction of the Alexandra palace, destroyed by fire June 9, 1873.—In 1863 an exhibition was held in Constantinople, national for Turkish manufactures, and universal for foreign implements and machinery. It was not important, but was made attractive by the display of jewels from the imperial palace and seraglio. The exhibition at Amsterdam in 1864 was devoted to the display of Dutch industry, and in the same year smaller local industrial shows were held at Malta, at Calcutta, and at Lucknow, and a combined French and Spanish exhibition was held at Bayonne. The South London and North London working-class industrial exhibitions began in 1864; the latter was the most important, having 934 exhibitors, 200,000 vis-

itors in the 18 days of the show, and a clear profit of £800. The international exhibition at Dublin in 1865, from May 8 to Nov. 9, had 770 British and 288 colonial and foreign exhibitors; but the visitors numbered only 600,000, a little more than half of the number in 1853, and financially it was a failure. In 1865 there was an exhibition at Oporto, confined chiefly to Portuguese industry, though there was a show of British agricultural implements and machinery. In the same year there was a show of New Zealand manufactures at Dunedin; an international exhibition, chiefly agricultural, by Germany, Holland, and Belgium, at Cologne; and an interesting international display of fishing tackle, &c., at Boulogne. Working men's local exhibitions were also held at Birmingham, Nottingham, Manchester, Preston, &c., and one at Vienna which distributed 613 prizes to 1,025 exhibitors, and made a profit of 2,000 florins, which was given to city charities. Several comparatively small working-class industrial shows were held in London, but only one of them was financially successful. Of two similar exhibitions in London in 1866, one, by having a hall rent free, secured a small surplus, which was distributed in prizes; the other had 1,492 exhibitors and 53,000 visitors, and, with £1,066 rent, made £900 profit. In 1866 Sweden, Norway, Denmark, and Finland combined in a show of Scandinavian industry at Stockholm, in which manufactures in iron, steel, woollens, and earthenware were principal features. The Melbourne exhibition of the same year assembled 3,360 exhibitors from South Australia, Victoria, New Zealand, New South Wales, Queensland, and Tasmania. The Brazilian exhibition of 1866, first at Pernambuco and afterward at Rio de Janeiro, was mainly of raw produce, which was subsequently sent to the Paris exhibition.—The Paris universal exhibition of 1867 was held in the Champ de Mars, in an oval building 1,550 ft. long and 1,250 ft. wide, covering 11 acres, while smaller buildings increased the area to 35 acres. Seventy surrounding acres, partly laid out as a garden, were covered with all kinds of buildings, including model cottages, restaurants, theatres, and even places of worship. The main building was a series of ovals one within another, starting from a central pavilion containing the coins, weights, and measures of all nations. The ovals were devoted to the following uses: 1, to works of art; 2, to materials, &c., of the liberal arts, printing, books, stationery, surgical, scientific, mathematical, and musical instruments; 3, to furniture and household goods; 4, to clothing; 5, to raw materials; 6, to tools and light machinery; 7, to cereals, vegetables, food preparations, &c. There was also a gallery which exhibited the progressive history of labor. From the central pavilion avenues radiated like spokes through the ovals, and the spaces between the avenues were assigned to different countries, so that visitors making the tour of

each oval could compare the productions in each class of the different nations. The exhibition was open from April 1 to Oct. 31; there were 50,226 exhibitors and 10,200,000 visitors; the medals and honorable mentions numbered, with 44 grand prizes for especial merit, 12,944, of which United States exhibitors received 3 grand prizes, 17 gold, 66 silver, and 94 bronze medals. The exhibition expenses, including buildings, were about \$4,000,000, of which the government and city paid \$2,500,000; the receipts for admissions, &c., were \$2,000,000; and there was a claimed profit of about \$600,000. A fishery exhibition at Havre in the same year included fishing boats and all the appliances for curing fish, making fishermen's clothing, &c. A still more important international maritime exhibition of marine engines, nautical instruments, ships' fittings and furniture, fishing boats and tackle, life-saving apparatus, &c., was held at Havre in 1868.—There was a local exhibition of the industries of the Northwest Provinces of British India at Agra in 1867, and local industrial exhibitions were held in St. Petersburg, Ghent, and Berlin in 1868. The Amsterdam international exhibition of 1869 had 2,325 exhibitors, and was remarkable for its display of cheap clothing, prepared foods, house fittings, furniture, and other articles of domestic economy. The St. Petersburg industrial exhibition of 1870 was local, to show the Russian progress in the manufacture of steel guns, armor plates, rails, locomotives, &c. The intercolonial exhibition at Sydney, New South Wales, in 1870, was important in the exhibition of raw products, preserved meats, &c. It had 2,914 exhibitors, was open 29 days, and there were 184,000 visitors. The London annual international exhibition of 1871, from May 1 to Sept. 30, was the third in the originally proposed decennial series, but was made the first of an annual series, each to be devoted to specified branches of industry. It had 1,142,154 visitors; there were about 4,000 fine-art and 7,000 industrial entries, and 33 foreign countries were represented. There were no prizes, and the receipts were equal to the expenses. The Italian industrial association began at Milan in 1871 a series of annual exhibitions, each year to be devoted to specialties. Naples held an international maritime exhibition in 1871. Minor exhibitions were held in 1871, at Jersey, of the products and industry of the Channel islands; at Lima, of the products and manufactures of the South American Pacific states; and at Cordova, of Argentine industry and of foreign implements adapted to the development of local resources. The London annual international exhibition of 1872 was devoted principally to the show of arts connected with printing, paper, music and musical instruments, jewelry, cotton goods, and fine arts. The Dublin exhibition of the same year comprised chiefly Irish produce and manufactures, and was held in the building erected

in 1853, which had been purchased by Sir Arthur Guinness, and was given rent free for this exhibition. Other exhibitions in 1872 were the international one at Moscow, intended to compare the progress of Russian industry with that of other nations; the show of Scandinavian industry, with 4,000 exhibitors, at Copenhagen; the universal exhibition of silk, silk goods, furniture, machinery, tools, fine arts, &c., at Lyons; and the display of Colombian products and manufacture at Bogotá. In 1873 the London annual international exhibition made a feature of cooking science and apparatus. There was a school of popular cookery, with lectures which from April 14 to Aug. 15 were attended by 31,784 persons.—The Vienna international exhibition of 1873 was opened by the emperor May 1; the prizes were distributed Aug. 18; and the exhibition closed Oct. 31. The main building, of brick and glass, erected on the Prater, was 2,985 ft. long, 82 ft. wide, and 52½ ft. high, with a central dome; and opening out from this hall were 32 transverse galleries 250 ft. long and 49 ft. wide, the whole presenting a form which was compared to a gridiron, or to a fish's spine with the projecting bones. There were also a machinery annexe of brick 2,614 ft. long and 155 ft. wide, a large fine-art hall, and numerous smaller buildings. The transverse sections were devoted to different countries in the order of their geographical position, beginning at the southwest main entrance with North and South America, thence in succession to Great Britain, France, Spain, Scandinavia, Germany, &c.; China and Japan occupying the remotest sections at the northeast end. The exhibits were classified into 26 groups, following nearly the plan of the divisions in the great exhibitions of London and Paris; but there were such special features as group 16, devoted to the art of war, and including everything for the equipment of an army and the care of the sick and wounded; 17, covering everything relating to sea, lake, and river navigation, ship building and fitting, construction of harbors and lighthouses, &c.; 19, private dwelling houses, inner arrangements, and decorations, to illustrate the domestic economy of different nations; 20, farm houses, furniture, and utensils of different countries; 23, art applied to religion in all the industries and fine arts employed in public worship. There were efforts also to show a history of prices of various important articles, at average periods of five years, as far back as possible, and the gradual conversion of waste into use in manufactured articles. The industries of nearly all the world were represented. The prizes were: 1, grand diplomas of honor; 2, bronze medals for progress, merit, fine arts, good taste, and coöperators. Of these, 349 were awarded to 643 exhibitors from the United States. The total number of visitors was 7,254,687. The exhibition cost more than \$12,000,000; the original gov-

ernment appropriation was \$3,000,000, accompanied with a provision that it was not to be exceeded; and as the receipts from visitors barely paid the running expenses, there was a deficit of about \$9,000,000. Among the causes which contributed to this failure were the financial panic and the comparatively small number of visitors during the summer months, which was due partly to apprehensions of the cholera, and especially to the utterly inadequate accommodations and the extravagant prices of living. But the industrial benefits of the exhibition to the Austro-Hungarian dominions, in bringing their productions to the notice of the world, and especially in the introduction of American agricultural implements and other foreign labor-saving inventions, were regarded as more than compensating the loss. The advantages gained by foreign exhibitors of valuable productions were also very great.—Of other industrial exhibitions in the United States, besides the world's fair in 1853, the most important are those of the American institute of the city of New York, founded in 1828, and incorporated in 1829, for the encouragement of commerce, manufactures, and art. For several years the annual fairs were in part agricultural and horticultural, but lately they have been almost wholly industrial, and are open to exhibitors from all parts of the Union. The large space required for the fairs has compelled the use in successive seasons of such places as Castle Garden, the crystal palace (1854-'8), and now (1874) the premises known as the "Rink," near the Central park, which the institute has purchased. The association has a fund of \$75,000 in government bonds, and owns real estate in New York renting for \$12,000 a year. Its fairs are profitable. The 42d exhibition, in September and October, 1873, had 1,146 exhibitors and more than 600,000 visitors; the receipts from admissions and other sources were \$63,322 32; expenditures, \$48,675 94; profit, \$14,706 38. The Franklin institute of Philadelphia, similar to the New York American institute and founded about the same time, is especially devoted to the mechanic and inventive arts, and has held occasional exhibitions; it also publishes a valuable journal, which at the close of 1873 had reached the 93d semi-annual volume. An association in Cincinnati has held four industrial exhibitions, and the fifth is announced for September, 1874. The ninth industrial exhibition of the mechanics' institute of San Francisco, from Aug. 18 to Sept. 18, 1874, is announced as "open to all the world." Baltimore, Boston, and Buffalo have held successful local industrial exhibitions. For several years past nearly all the county and state agricultural societies throughout the Union have made annual exhibitions of local manufactures, industries, and arts, as well as of agricultural products, with liberal prizes to competing inventors, manufacturers, and exhibitors.—Among important industrial exhibi-

tions that are now projected may be mentioned an international one of female industry at Florence, probably in 1874. The announcements of special industries to be exhibited at the annual internationals in London are made for each year from 1874 to 1880. A law of congress, March 3, 1871, authorizes "the celebration of the centennial of American independence by an international exhibition of the arts, manufactures, and natural resources of this and other countries." The proposed exhibition is to be held in Philadelphia from April 19 to Oct. 19, 1876. An act of congress, June 1, 1872, fixed the capital at \$10,000,000, which the commissioners apportioned among the states according to population. Up to June, 1874, New Jersey had appropriated \$100,000, Pennsylvania \$1,000,000, Philadelphia \$1,500,000, and local subscriptions, together with individual subscriptions throughout 25 states and territories, brought the sum total to about \$4,000,000; and an effort was in progress to procure private subscriptions for the balance.—Among the more important works relating to the principal exhibitions are: "The Official Catalogue of the Great Exhibition of 1851" (4 vols. 4to, London, 1851); "Official, Descriptive, and Illustrated Catalogue" of the same (3 vols.); "Reports by Juries" (6 vols.); "First Report by Commissioners" (1852); the elaborate work printed for the commissioners (13 vols. fol.), and the same in French (13 vols. 8vo, Paris, 1857-'66); "Report of the World's Fair" (New York, 1853); *Exposition universelle de 1855*, by the French commission (3 vols. 8vo, Paris, 1857-'8); "Reports of the International Mixed Jury" (in French, 2 vols. 4to, Paris, 1856; in English, London, 1856); the reports of the royal commissioners on the exhibition of 1862 (4 vols., London, 1862); "The Exhibited Machinery of 1862," by D. K. Clark (London, 1862); the reports of the French and English commissioners on the Paris exposition of 1867 (Paris and London, 1867); reports of the United States commissioners on the same (6 vols., Washington, 1870); the special report on "Machinery and Processes of the Industrial Arts and Apparatus of the Exact Sciences," by F. A. P. Barnard, LL. D., a commissioner for the United States (Washington, 1869); and "Reports of Artisans selected by the Society of Arts to visit the Paris Universal Exhibition of 1867" (London, 1867). No comprehensive work on the Vienna exposition of 1873 has yet appeared (1874), though several minor reports have been published.

INES DE CASTRO. See CASTRO, INES DE.

INFALLIBILITY (later Lat. *infallibilis*, not liable to be deceived, from *in*, privative, and *falli*, to be deceived, to err), a doctrine of the Roman Catholic church, which attributes to that church as the divinely appointed teacher of mankind, and to the Roman pontiff as pastor of the whole church, the privilege of being preserved from teaching error. Infallibility is not to be confounded with impeccability, which means im-

munity from sin. The special assistance of the Holy Spirit which preserves a person from error in the discharge of a certain office is a grace of the supernatural order, called by theologians *gratia gratis data*, a grace bestowed for the benefit of others than the recipient, such as the power of the priesthood bestowed on good and bad alike, and the gift of prophecy found in such men as Balaam and Caiaphas. It is thus distinguished from graces which are vouchsafed to sanctify their possessor, like that by which John the Baptist and Jeremiah were sanctified before their birth; a grace of this sort is called *gratia gratum faciens*. The privilege of infallibility is also to be distinguished from inspiration; because inspiration in many cases means a new revelation, whereas both the church and the pontiff are only witnesses, teachers, and judges of the revelation already made, and are merely preserved from error in guarding, expounding, and defending the deposit of revelation. By the dogmatic decree of the council of the Vatican, the infallibility traditionally ascribed to the church by Catholics is declared to have been directly and immediately conferred on St. Peter, and in him on his successors the bishops of Rome. I. Roman Catholic theologians ground the infallibility of the church principally on the texts of Matt. xxviii. 19, 20: "Go ye, therefore, and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost; teaching them to observe all things whatsoever I have commanded you: and, lo, I am with you always, unto the end of the world;" and Mark xvi. 15, 16: "Go ye into all the world, and preach the gospel to every creature. He that believeth and is baptized shall be saved; but he that believeth not shall be damned." These words of Christ, constituting the great commission or charter of the church, as they maintain, established her as the universal and perpetual teacher of mankind, gave into her keeping the deposit of the divine faith and law, declared her office to be that of sole interpreter of the same, bestowed on her the sole jurisdiction existing upon earth in matters of salvation over the reason and will of man, and assured her that in the discharge of this office she will have the Lord with her until the end of time. Faith in Christ through her teaching, and obedience to her in the fulfilment of her office, are required under pain of damnation. Now, it is held to be repugnant alike to the nature of God and to that of man, that God should compel the assent of the reason and submission of the will to a teaching liable to error. The object or matter embraced by this infallible teaching is the whole body of revealed truth written and unwritten, and all that is so connected with it that without treating of it the Word of God could not be guarded, expounded, and defended; such would be the declaring of the canon, authenticity, and true interpretation of Scripture, and the like. Further, the church claims an infallible guidance

in discerning and defining all matters which are opposed to revelation; for, it is argued, she could not discharge her office of teacher of mankind, unless she were able to proscribe with infallible certainty all doctrines at variance with the Word of God. Hence, the direct object of the infallibility of the church is the revelation or Word of God; and the indirect object is whatever is necessary for its exposition and defence, or contrary to the law of faith and morality. II. Pontifical infallibility is thus defined in chapter 4 of the constitution *Pastor æternus*, July 18, 1870: "We teach and define that it is a dogma divinely revealed, that the Roman pontiff, when he speaks *ex cathedra*, that is, when, in discharge of the office of pastor and doctor of all Christians, by virtue of his supreme authority, he defines a doctrine regarding faith and morals to be held by the universal church, by the divine assistance promised to him in blessed Peter, is possessed of that infallibility with which the divine Redeemer willed that his church should be endowed for defining doctrines regarding faith and morals; and that, therefore, such definitions of the Roman pontiffs are irreformable of themselves and not by the consent of the church." This definition declares that the pope is infallible when speaking from his seat of authority, in discharge of his office of pastor and teacher of the entire Christian fold, and challenging the assent of the universal church. The doctrinal point defined or finally decided must relate to faith and morals, and in such definitions, it is declared, he is divinely guided by virtue of the promises made to him in the person of Peter. This infallibility of the pontiff has the same extension as the doctrinal office of the church, and the final judgments pronounced in its exercise are in themselves irreformable or irreversible, even before the church has accepted them. The definition limits the infallibility and the divine assistance which secures it to the pope's official acts as pastor and doctor of all Christians. It thus excludes all his acts as a private person, doctor, theologian, local bishop, or ruler. He is exempt from error in only one capacity, that is, when as teacher of the whole church in faith and morals he speaks from the chair of Peter. The phrase doctrine of faith and morals signifies the whole revealed Word of God, the whole way of salvation through faith, or the whole supernatural order with all that is necessary to the salvation of mankind through Jesus Christ. The efficient cause of this infallibility or immunity from error is declared to be the divine assistance promised to Peter, and in Peter to his successors. This, it is asserted by Catholic theologians, is contained explicitly in the words of Christ to Peter, Luke xxii. 32: "I have prayed for thee, that thy faith fail not: and when thou art converted strengthen thy brethren;" and implicitly in Matt. xvi. 18: "And I say also unto thee, That thou art Peter, and upon this rock I will build my church; and the

gates of hell shall not prevail against it." The assistance thus promised and its effect are a divine ordinance. It is further affirmed that before the definition of the Vatican council, the infallibility of the pontiff was a doctrine revealed by God, delivered by the constant tradition of the church, recognized in œcumenical councils, presupposed by the acts of the pontiffs in all ages, taught by all the saints, defended by every religious order, and by every theological school except the Gallican, and in that school only disputed by a numerical minority and during one period of its history, and believed at least implicitly by all Catholics. The definition, Catholics believe, has added nothing to the intrinsic certainty of this doctrine, which is derived from revelation. It has only added the extrinsic certainty of universal promulgation, binding the whole church to believe the dogma explicitly.—The doctrine of pontifical infallibility, theologially considered, is intimately connected with the pontifical supremacy; and, considered historically, it is seen that from the exercise of the supremacy was gradually evolved and finally asserted the prerogative of infallibility. The bishops of Rome at a very early period claimed a supreme and final authority in deciding all ecclesiastical disputes; and this claim they founded on the fact of the see of Rome being the seat of Peter's authority, and of their being his successors with supreme jurisdiction over the entire church. On the other hand, the opposition to the exercise of this supremacy forms a parallel and continuous record in the early church down to the consummation of the Photian schism. Thus, in the ante-Nicene period Pope Victor I. (about 193) claimed to decide finally the controversy about the proper day for celebrating Easter, and excommunicated the Asiatic churches which refused to abide by his decision; and Pope Stephen I. (253–257) decided against St. Cyprian and the churches of northern Africa, that baptism performed by heretics should not be repeated, and annulled the sentence of a Spanish synod against two bishops. But the decision of Victor was set aside by the Asiatic bishops; and in like manner the bishops of Africa and Spain persisted in upholding their own local customs and established rights. Earlier still Tertullian, in his treatise *De Pudicitia*, complained that the Roman pontiff issued peremptory edicts, as if he were "bishop of bishops." From the time of Constantine the Great this exercise of supremacy, and the right on which it was founded, were brought into greater prominence by the part taken by the Christian emperors in convening councils and enforcing their decrees, by the conflicts which occurred between the councils themselves and the authority of the popes, and by the contests for preëminence waged by the see of Constantinople with the patriarchal sees of the East, and with Rome herself. Thus Leo the Great received the appeal of Celidonius, bishop of

Besançon, deposed by Hilary of Arles, and restored him to his see; thus, also, it is maintained, his doctrinal letter was received as a final decision by the council of Chalcedon (451). Another document quoted by ultramontane theologians as pointing to an exercise of supremacy, is a letter of Pope Gelasius in 493, in which it is said: "The canons themselves refer the appeal of the whole church to the examination of this chair. They decree that from it there is no further appeal, and by it the whole church is judged; it goes for judgment to none, nor can its judgment be judged, nor its sentence reversed." (Labbe, vol. iv., p. 1169.) Against this claim of deciding all ecclesiastical causes without appeal, thus distinctly formulated in the 5th century, is quoted the recently established fact of the Roman presbyter St. Hippolytus having been at the time of his death in opposition to the pope, his superior, as well as the instances in which popes fell into heresy or encouraged heretical opinions. Such were the cases of Zozimus, who commended the Pelagian teaching of Celestius; Julian, who affirmed the orthodoxy of the Sabellian Marcellus of Ancyra; Liberius, who subscribed (359) the Arian creed of Rimini; Vigilius (547), who contradicted himself thrice on a question of faith; and Honorius, who lent the whole weight of his authority (633) to the support of the nascent Monothelite heresy, and was solemnly excommunicated by an œcumenical council for doing so. Still the bishops of Rome persisted in their claims, while in the East the resistance to them grew as the patriarchs of Constantinople rose in power and influence among the eastern hierarchy, until the conflict of jurisdiction ended (879) in the disruption of Christendom. In western Europe the primacy of the Roman bishops continued to be universally acknowledged after the separation of East and West; but their personal infallibility was never maintained in a formal theological thesis till the time of Thomas Aquinas. He however does not employ the term infallibility; he says that the same security from error in teaching, judging, and determining all that pertains to faith, which is ascribed to the church, belongs also to the Roman pontiff, by virtue of the promise made to Peter. The thesis, thus placed in distinct form before the great theological schools of Europe, soon acquired increased definiteness and interest from the contests between temporal princes and the popes, and between rival claimants for the papacy and the ecclesiastical assemblies convened to heal the great western schism. Philip the Fair in 1303 declared his intention of calling a general council to judge Pope Boniface VIII. In the council of Constance, where the French clergy largely predominated, the French theologians D'Ailly and Gerson proposed the framing of a decree declaring an œcumenical council superior to the pope. In the council of Basel, soon afterward, this superiority was urged against Euge-

nus IV., particularly after he had dissolved that body. The superiority of œcumenical councils to papal authority was embodied in the pragmatic sanction of Bourges in 1438, both as a theological maxim and as a rule of national jurisprudence. Thenceforward the theologians in France who maintained this superiority were called Gallicans, and their opponents ultramontanes. Gallicanism, considered as a system of jurisprudence and theological doctrine, comprised the liberties or franchises of the Gallican church, and the peculiar tenets of its churchmen with regard to the nature and limits of the pontifical supremacy. These Gallican franchises were understood in one sense by the churchmen, and in quite another by French magistrates. In reality they affirmed that the pope had no right, by virtue of his supremacy, to interfere with the king in the holding of his crown or the lawful exercise of his power; that the election of ecclesiastical dignitaries, the collation of benefices and the disposition of their revenues, the imposition and collection of taxes on church property, belonged by inherent right and custom exclusively to the church of France, under the protection of the king. These franchises, and the peculiar doctrine of the Gallican church concerning the pope's inferiority to a general council, were formulated in six articles presented by the Sorbonne to Louis XIV., May 8, 1663, which were reaffirmed with greater solemnity in 1682. The famous "four articles" then proclaimed by the assembled clergy, besides the absolute independence of the civil power, declared that the plenitude of power in spirituals possessed by the successors of St. Peter is to be limited by the decrees of the council of Constance, which have ever been in force in the Gallican church; that the use of the pope's apostolic power is to be regulated by the canons, and within the kingdom of France by the received rules, customs, and constitutions; and that, although the pope has the chief authority in questions of faith, and his decrees regard all the churches, and each church in particular, nevertheless his judgment is not irreformable until the consent of the whole church supervenes. The whole question of infallibility continued to be vehemently discussed by Jesuits and Jansenists, Gallicans and ultramontanes, down to the French revolution. When public worship was restored by Bonaparte, the concordat concluded with him by Pius VII. abolished the old French hierarchy with all its privileges, and established new sees and new ecclesiastical dioceses. But Bonaparte inserted in the concordat, on its publication, what is known as the "organic articles," which among other things reaffirmed the offensive portion of the declaration of 1682. This was maintained as the law of the land and a rule of state policy through every change of government, although Gallicanism itself was constantly on the wane. In 1867 it was resolved by Pius IX. and the bishops assembled in Rome

that an œcumenical council should be convened without delay; and it soon became generally known that one of the doctrinal questions to be decided in the council was that of pontifical infallibility. A warm discussion immediately began as to the opportuneness as well as the possibility of such a definition. Conspicuous among the opponents of the contemplated measure was Dr. Döllinger of Munich, and among its promoters Archbishop Manning of London. The Jesuits, always the most strenuous advocates of papal prerogative, used all their influence to secure the definition. In France the bishops were divided; in England, Ireland, the United States, Germany, and Austria, a majority would have preferred delay; but Italy and Spain were for instant definition. Among the European governments a strong diplomatic effort, originating with Bavaria and seconded by France, was made to dissuade the court of Rome from a step deemed full of danger. On Dec. 8, 1869, the council was opened by Pius IX. in the Vatican basilica of St. Peter's. A first doctrinal constitution on Catholic faith, having been elaborated and accepted, was officially proclaimed, April 24, 1870. Then began the discussion of a second constitution "on the church," ending with the decree on pontifical infallibility. Outside the council itself, the dogma in its theological and historical aspect, and its bearing on the relation of the church to civil governments, was vehemently discussed in the press. A correspondence between Bishop Dupanloup and Archbishop Manning, and the publication of an exhaustive Gallican argument by M. Maret, bishop of Sura, had created much interest just before the opening of the council; and this was largely increased by the appearance during its sittings of a series of letters in the Augsburg *Allgemeine Zeitung* signed "Janus," afterward published in book form with the title of "The Pope and the Council." (See DÖLLINGER.) Another series of letters from Rome were printed in England from the pen of "Quirinus," while two more issued from the French press entitled *Ce qui se passe au concile* and *La dernière heure du concile*. Within the council itself every portion of the *schema* or draught was warmly discussed. On July 11 the *schema* of the chapter on infallibility was discussed in detail and adopted in a general congregation; and the whole *schema* was put to the vote in another congregation held on the 13th. Each prelate voted *placet*, if content; *placet juxta modum*, if only content with a part; or *non placet*, if not content. The register showed 451 as voting *placet*, 62 *placet juxta modum*, and 88 *non placet*. On July 18, in solemn session, 534 prelates answered *placet*, 2 *non placet*, and 65 were absent, of whom a majority did not wish to vote favorably.—See Archbishop Manning's *Petri Privilegium* (London, 1871), and "The Pope and the Council," by Janus (Boston, 1870). (See also OLD CATHOLICS.)

INFANT. All persons are called infants, by the common law of England and America, until the age of 21, though in Vermont, Maryland, Illinois, and perhaps some other states, by statute, women are of full age, for most purposes at least, at 18. An infant becomes an adult, or of full age, at the beginning of the last day of his 21st year, or the day before his 21st birthday, upon the ancient principle that the law knows no parts of a day, and when the last day of infancy begins, it is considered as ending. The most general principle in reference to the legal condition of an infant is his inability to bind himself by his contract. The law asserts this inability for the sake of the infant, not as a restraint, but as a protection to him, and finds that upon the average of mankind this protection should be extended until the age of 21. This inability being intended for his protection only, in legal phrase it is said to be his shield, and he must not use it as his sword. Because it is for his benefit, the first and most important exception is, that he may bind himself by his contract for necessities; for it might harm and could not help the child if he were unable to pledge his credit for shelter, clothes, or food. At first the exception was confined to strict necessities; but it has been gradually extended, until now it is frequently said to mean all those things which it is perfectly proper for the infant to have, taking into view his age, his means, and his condition or circumstances. Thus he may make a valid bargain for clothes, or even ornaments or furniture, as well as food and lodging, more expensive than another may need, but not extravagant or superfluous for him. In England it has been held that instruction in reading and writing is among these necessities for every one who could pay for it. In the United States it is held that the full benefit of a good school education is among these necessities; and there seems to be no reason to doubt that a collegiate education will be held within the rule. So, as an infant may lawfully marry, necessities for his wife and children may be lawfully contracted for by him. The line is drawn so as to exclude quite distinctly all trade or business bargains; for the whole legal doctrine of infancy rests on the assumption of the infant's inability to carry on the business of manhood until he has the maturity of at least 21 years. And it should be noticed that not all his contracts even for necessities are, strictly speaking, valid. Thus, if he buys suitable food or clothing, and agrees to pay a certain price therefor, or gives his note therefor, he is not bound to pay that price or that note; but if sued on the promise, he may defend so far as to show that the food and clothing were not worth as much as he promised to pay, and then he will be held only for their value. But he cannot avoid his obligation to pay their full value, merely because he promised to pay too much. Formerly the distinction was, that an infant's contracts, not for

necessaries, were entirely void, if the court saw that they could not be beneficial to him, but only voidable by him if this were doubtful. Now, however, the prevailing rule is, that all contracts of an infant, not for necessities, are voidable by him, but that none are void; because all may be made valid by his ratification after full age, which could not be the case if they were wholly void at their inception. Any acts or words of affirmance on his part have the effect of this ratification, if they are made after majority; but a mere acknowledgment that when he was an infant he made such a promise, does not bind him when adult. The mere fact that, after full age, he does not disaffirm his contract made in infancy, does not amount to a ratification; but it may be made to have this significance and effect by circumstances, and certainly has this effect if after majority he voluntarily continues for any considerable time in use, possession, and ownership of property acquired by his contract made while an infant. A distinction is taken here between an infant's real estate and his personal estate; and it is said that he may ratify a contract for the latter with much less of formal and positive ratification than is necessary for the confirmation of his conveyances of real estate. Still, a silent acquiescence in the possession of his grantee, if long enough, and with full knowledge of his rights, may amount to ratification.—As the disability of an infant is only for his personal benefit, no one can take advantage of it but himself or his legal representatives. Therefore, if an adult makes a business contract with an infant, the adult is bound, although the infant is not. Thus, an infant may sue an adult for a breach of promise of marriage; but neither an adult nor an infant can sue an infant for such breach. So an infant may bring an action on a mercantile contract, although such an action cannot be brought against him. It is sometimes important to determine whether an infant is bound by the obligations which attach to property that he acquires by his contract. If he takes the property by direct operation of law, as by descent or marriage, there is no question, for the rule *transit terra cum onere* would apply, and be extended even to property that was not land. But if he acquires the property by his own act, the law may not be so certain. Thus, an infant who takes a lease of land, and holds possession until rent is due, is bound to pay the rent, like any other person; but he may, when he will, disclaim the land and annul the lease, or rather suspend the lease; for it is said that when he is of age he may avoid his disclaimer. So, if he buys stock in a corporation, he is liable like an adult for assessments and calls, but may waive his contract and give up his stock. While an infant is protected against his contracts, he is not protected against his acts; that is, he is answerable in like manner as any other person for the injury he inflicts by his wrong doing, excepting so far as actual infancy or im-

maturity tends to make him irresponsible, or to excuse him, as an equal amount of actual incapacity would excuse any one. But, in the case of tort, as before in the case of contract, if he gives his promise or his note as a compensation for the wrongs he inflicts, he would be held not on his promise, but only to the extent of his original liability. The most interesting and the most difficult application of the rule, that an infant is liable for his wrong doings, occurs in relation to his frauds in representing himself as of full age. Where his tort is merely the breach of his contract, he cannot be sued on the tort, for this would be holding him indirectly to his contract. But if there is a distinct wrong for which he is responsible, he is answerable, although it be connected with the contract; and this, whether it be before or after the contract. Thus, if he hires a horse for an unnecessary ride, he is not liable for the hire; but if in the course of the ride he abuses and injures the horse, for this we should hold that he would be liable; and if he should sell the horse, an action for its value would lie, nor would his infancy be a bar. So if he falsely and fraudulently represents himself as of full age, and on the strength of these representations his note or bond is received in payment for a purchase, he cannot be held on the note or bond, nor as purchaser for the price of the goods; but the purchaser may have redress in the proper action for his fraud. And it would seem that infancy should not be a bar to an action founded upon a false and fraudulent warranty, although on this point the authorities are in conflict. So if goods are sold to an infant on his fraudulent representation that he is of age, we should say that the seller might consider the sale null and void, and reclaim his goods as soon as he discovers the fraud; but perhaps not until his refusal to pay, or some other indication of his intending injury. We do not think, however, that his mere silence, and his permitting the seller to act on the supposition that he was of full age, would have this effect. When goods are sold to an infant with no fraudulent representation on his part, and with a knowledge of his infancy on the part of the seller, and the infant subsequently refuses to pay for them, and avails himself of his infancy, as he certainly may, to refuse payment of the price, some doubt, or at least some conflict, exists as to the rights of the seller. Some authorities hold that the seller is remediless, because the privilege of the infant protects him altogether. Other authorities hold that this privilege goes no further than to permit him to cancel the sale if he will, for this is quite enough for his protection; and when the sale is cancelled, its effect is wholly destroyed, and the thing sold becomes again the property of the seller, who may repossess himself of it at his pleasure. It seems to be universally admitted that if the infant has received the goods and paid for them, he may return the goods and recover the money, but

cannot recover the money without returning the goods.—A very important part of the law of infancy, and that which perhaps gives rise to more disputes and litigation than any other, is that which determines the obligation of the parents in respect to infant children. Unfortunately, a part of this law is not quite settled. In some form or other, and in some degree, the obligation of a father to maintain his infant child is acknowledged by the law of all civilized communities. For the infant cannot support himself, and therefore some one must do it; and then the only question is, whether this obligation falls directly on the state, or in the first place on the father. Justice and reason and all the best feelings of human nature would seem to answer that it is primarily the duty of the parent. But in England, after some uncertainty, and with some reluctance, and perhaps some tendency to make this moral obligation of the father a legal one also, it seems now to be the prevailing and perhaps established rule, that there is no other foundation for the liability of the father for necessities supplied to the child, excepting the principle of agency; that is, the father is liable only when the child contracts for them, and may be deemed the agent of the father in making the contract. In a number of our states this doctrine has been very positively asserted. But in England, and in all of the United States which require the father's authority to be proved, this authority is inferred from very slight evidence. Perhaps no case goes so far as to say directly, that if a father sees or knows that goods are supplied to his infant child, and he does not signify his dissent, his assent and responsibility may be inferred; but some of them go, in fact, to almost this extent. But the question occurs: How would these courts decide where the case was one which made agency or authority impossible? As if an infant of a month old, or an older child reduced to utter incapacity by starvation or illness, were lost in a wood, and found by a person who supplied him with strict necessities; would he have no claim on the father? Perhaps the law on this subject cannot be said to be determined either in England or America; but as prevailing rules, in this country at least, derived from an investigation and comparison of the authorities, we should say: 1, where goods are supplied to an infant which are not necessities, the father is not answerable unless his authority can be proved in the common way; 2, where necessities are supplied, his authority will be presumed, unless he either supplied them himself, or was ready to supply them; 3, where an infant lives with the father or under his control, the father's judgment as to what the child should have will be so far respected, that he will be held liable only for those things which were strictly necessary to preserve the child from absolute want and suffering; 4, where the child has voluntarily left the father, and does not live with him, the

father's authority must be strictly proved, unless in case of extreme youth, or perhaps of absolute necessity; 5, where the child has been cruelly driven away by the father, he carries with him the father's credit for necessaries; 6, in all these rules, "necessaries" mean strict necessities; and if the child is able to earn or provide them in part, this must be taken into consideration. Where a child has an independent property of his own, courts now go, in general, very far in requiring this to be made the fund for his support, before the father is called upon. Whether the mother is under the same liability as the father may not perhaps be certain; but we consider the decided weight of authority as qualifying the mother's liability importantly, even where its existence is admitted.—The father thus liable for the child is entitled to its custody (unless for special reasons), and is also entitled to all the child's earnings; but he may agree with his minor child to relinquish his right, and thereafter to have no responsibility for his support. Such agreements are common in the United States; but if a stranger supplied a minor child, at a distance from home, with strict necessities, to save his life or health, even with knowledge of this bargain, we are not disposed to believe that it would bar his claim against the father. If a child is of full age, the obligation to support him is so entirely gone, that even if a father, after necessities are supplied to an adult child without his request, promises to pay for them, he cannot be held on this promise, because there is no legal consideration for it. It may be added that if an infant, while under his father's care, and actually supported by him, makes a contract even for necessities, and gives his own promise to pay for them, the infant is not liable on this contract or promise, because, as it is said, this would interfere with the father's right to judge what is necessary for him. Perhaps a better reason is, that in such a case these things are not necessary in any proper sense of the word, for the very reason that the child derives a sufficient support from the care of the father.—A father is never liable for the wilful tort of an infant child; nor has he a right, merely as father, to bring an action in his own name for an injury to his child, unless in some way, as by the necessary expense or otherwise, he is himself injured. Neither can he give a valid release for an injury to his child.

INFANTE (Lat. *infans*, infant), a title given in Spain and Portugal to the royal princes, the eldest of whom, the heir apparent to the crown, is alone called *el príncipe*, the prince. The feminine form of the word, *infanta*, is applied to the royal princesses. The term *infante* occurs in documents of the 10th century.

INFANTE, José Miguel, a Chilean statesman, born in Santiago in 1778, died April 9, 1844. He was one of the earliest leaders of the revolution of 1810, which ended in the independence of Chili; contributed to organize the *junta gubernativa* in the same year, and the

first congress, which assembled on July 4, 1811; and was a member of the new junta of 1818. In 1818 he became minister of finance under O'Higgins, against whom on Jan. 2, 1823, he delivered a noted speech. O'Higgins shortly afterward resigned, and the country was then governed by a junta, of which Infante was the first member, until the election of President Freire, by whom Infante was called to organize a senate. During the first session of that body, his bill for the abolition of slavery was enacted, June 24, 1823. Freire being absent in 1825, the government was reposed in a dictatorial council with Infante at its head. He advocated the formation of Chili as a federal republic, and founded a newspaper, the *Valdiviano Federal*, which he published from Jan. 1, 1827, till near his death. In 1831 he was appointed member of the congress of plenipotentiaries, and in 1843 chief judge of the supreme court of justice, and member of the faculty of law of the university of Chili. He was influential in establishing primary schools, and has been called the "father of his country."

INFANTRY, the foot soldiers of an army. The term is comparatively modern, having been first used by the Spaniards in the wars with the Moors, to designate the body guard of a royal prince or *infante*. It was gradually extended to the entire body of foot soldiers, and finally adopted throughout Europe. (See ARMY.) The infantry, from its powers of endurance, its capabilities for battle on all kinds of ground, and its independence of those casualties by which other arms may be completely paralyzed, is, and with few exceptions always has been, considered the first arm in importance. All other branches are subsidiary to it, and are employed for special purposes to supplement its final effects; and the fate of nations in war at the present day is decided by the discipline and efficiency of their infantry. The service of skirmishing and light infantry operations, as they were formerly called, which now devolve upon all infantry alike, demand great individual address, intelligence, and well developed physical power. It is generally conceded that against infantry operating with the modern breech-loading weapons, and with the improved system of tactics and defence, cavalry is powerless, except when operating dismounted and armed with breech-loading magazine rifles, or mounted to complete a victory already won, and to charge the disorganized and flying ranks. (See CAVALRY.) Artillery is of the utmost importance to cooperate with infantry, in opening engagements and in demoralizing the enemy with persistent shelling until the infantry is within firing distance. (See ARTILLERY.) The relative number of field guns varies with the ground and the special objects to be secured; from three to five guns to 1,000 men is the number adopted in most army organizations of the present day.—The lessons taught by history applicable to infantry of the present day are few and simple, but seem to

be forgotten or ignored by those in authority at the outbreak of almost every great war. They are, that the infantry soldier should possess the highest attainable mental, moral, and physical development; be governed by the strictest discipline, and show implicit and unquestioning obedience to the superior officer; be controlled by the simplest possible manœuvres in the field or in presence of the enemy; and be loaded as little as possible either with arms or equipment. From the Napoleonic period to within the last 12 or 15 years some modifications had been made with reference to infantry, but they were comparatively unimportant. Within this period, however, the invention of the rifle with the conical ball of Minié, the breech-loading needle gun of Dreyse, and a number of other modern improvements, have caused a very considerable change in the organization and manœuvring of infantry; and now the general introduction of the breech-loading rifle, with the improved system of field defences, has completely altered the phenomena of the battle field.—*United States.* The infantry of the regular army of the United States since the civil war has been reduced in numbers several times, and now consists of but 20 regiments, each composed of 10 companies, and each company on the peace establishment of 53 enlisted men. The officers of the regiment are a colonel, a lieutenant colonel, a major, a regimental adjutant, and a regimental quartermaster. Each company is commanded by a captain, and has one first and one second lieutenant, and may have an additional second lieutenant, a graduate of the military academy. The non-commissioned staff consists of a quartermaster sergeant and a sergeant major. Each company has one orderly sergeant, three common sergeants, and four corporals. Congress, when the necessity arises, authorizes the president, as commander-in-chief, to increase the army to the maximum standard. In each state there is a militia, in time of peace under the command of the governor, in time of war in certain contingencies, under that of the president of the United States, which conforms in all respects to the regular army in tactics and arms. (See MILITIA.) The arm of the United States infantryman is the Springfield breech-loading rifle. (See RIFLE.) The equipments are a knapsack with greatcoat straps, a haversack, a canteen, a cartridge box, and a bayonet scabbard. The uniform, for privates, consists of a single-breasted dark blue basque coat, sky-blue trousers, blue cloth cap with a white pompon; for officers, a double-breasted frock coat of dark blue cloth, the rank to determine the number of buttons, and light blue trousers with black stripes. The overcoat is a dark blue double-breasted surtout. (For detailed description, see general orders No. 92, war department, adjutant general's office, Oct. 26, 1872.) Privates and non-commissioned officers are liberally supplied with underclothing, blankets, and

waterproof blankets. They can either draw their clothing in kind or commute it. Officers and men are allowed a definite amount of camp equipage, consisting of wall tents, shelter tents, mess pans, camp kettles, hatchets, axes, and spades. In the field, officers are allowed a definite amount of baggage transported at the expense of the government. Privates are obliged to carry their personal effects on their person. The pay of the United States infantry is as follows: colonel, \$3,500 per annum; lieutenant colonel, \$3,000; major, \$2,500; captain, \$1,800; adjutant, \$1,800; regimental quartermaster, \$1,800; first lieutenant, \$1,500; second lieutenant, \$1,400; chaplain, \$1,500; first sergeant, \$22 per month; sergeant, \$17; corporal, \$15; private, \$13. An increase of 10 per cent. is allowed for every five years' service, provided the total amount of increase does not exceed 40 per cent. of the whole pay. Mounted officers are allowed forage for their horses. If quarters are not furnished by the government, commutation is allowed. An increase of \$1 a month for the third, fourth, and fifth years of the first enlistment is allowed to non-commissioned officers and privates.—The great lesson taught by the civil war in America was, that the defence derived an immense benefit from shelter, however slight. The rifle pit in the last years of the war was perhaps the most marked feature in the American system. Though generally not armed with a breech-loading weapon, but simply with the Springfield muzzle-loading rifle, experience showed that, so long as the men behind intrenchments preserved their *morale*, the damage inflicted on the enemy was frequently nearly ten to one. Skirmishing, which was adapted to the character of the American hunter and backwoodsman, and which was first introduced to general notice in the war of the revolution, received a new impetus in the civil war, and was constantly employed on both sides. The character of the ground, broken and timbered, also generally favored this system of warfare. The Prussians have since adopted the skirmish line as the normal formation for battle, having been compelled during the Franco-German war to abandon the attack in masses in consequence of the destructiveness of the breech-loader. They have since adapted their tactics to the new method of fighting. Cavalry cooperating with infantry was rarely used; but field artillery was brought to a state of great perfection, and was extensively used to open engagements and cooperate with the foot. The infantry was generally drawn up in one or two lines of battle in two ranks, with a reserve at a proper distance in the rear to supply gaps and strengthen that portion of the line most heavily pressed. The skirmishers were in advance whenever the enemy's position was not known. The attack was generally opened by a fire of artillery, followed by a gradual advance of the whole line, and finally a charge at a run. The system of

tactics used was that known as Casey's. It was an improvement on Scott's "Tactics," which was substantially a translation of the French *Ordonnances* of 1831 and 1845. Casey's system, which was succeeded by that of Hardee, was in turn superseded by that of Upton in August, 1867. This system, which is based upon a front of four men as a unit, seems the best adapted to meet the requirements of infantry manœuvres of the present day. To give the breech-loader its maximum effect, it provides a single-rank formation, and also a new method of deploying skirmishers by numbers, by means of which, without destroying the manœuvring unit of four, a battalion in line, in double rank, can promptly furnish one, two, three, and even four successive lines of skirmishers, each equal in strength to one eighth of the battalion. The first line, if too weak, may thus be reinforced by successive lines till one half of the battalion is engaged, leaving the other half in line in single rank, ready to advance to the support of the skirmishers if successful, or to receive them if repulsed. If necessary, the entire battalion may be advanced in successive lines or united into a single line of skirmishers. The term regiment is used in the United States for administrative purposes, and tactically is interchangeable with battalion, as it generally consists of but one, differing in this respect from most European armies, where a regiment is composed of two, three, and sometimes as many as seven battalions.—*Germany.* The highest division of infantry solely is the brigade, composed of two regiments, each regiment, with one or two exceptions, of three battalions of four companies each. Each regiment has a colonel, lieutenant colonel, and adjutant, besides a commander who is an officer of the staff, and one major as fifth officer of the staff. Each regiment has a band, varying in number. Each battalion, in war, has one wagon with munitions, containing from 16,710 to 16,940 cartridges and 1,290 explosive cartridges, 12 axes, 10 spades, &c.; one wagon containing the cash box of the battalion and accounts, articles of uniform in reserve, and the tools requisite for the shoemakers and tailors of the battalion; one cart containing drugs and medicines; one wagon for officers' equipage; and four horses with pack saddles. There are some slight changes in the arrangement for the fusileer and jäger battalions. There is little more than a nominal distinction between the different regiments of foot, those called fusileers and the battalions of jägers forming the light infantry. The fusileers have no bayonets on their guns, but use short swords instead. The jägers are, as far as possible, recruited from persons who wish to become game keepers and foresters, and have been assistants to such before entering the army. Each battalion has a major and an adjutant, a surgeon and one assistant surgeon, a paymaster, a quartermaster, and two non-commis-

sioned staff officers. Each company is composed of one captain, one first and one second lieutenant, and 250 enlisted men. The following table gives the numbers of the German infantry on a peace and on a war footing:

PEACE FOOTING.

The gun of the German infantry during the Franco-German war was the needle gun of Dreyse. It admits of firing five times in a minute, and carries well 800 yards. It is being superseded by the Mauser rifle, sighted up to 1,600 yards, which is capable of being fired 18 times a minute, and the adapted French Chassepot, 400,000 of which were captured in the war. The prevailing color of the Prussian uniform is blue, and the coat is much like that of our own troops. For infantry the coat is a dark blue frock, with a single row of eight buttons, the collar and cuffs faced with red; pantaloons dark gray, with red cord down the seam; the boots have tops about 6 in. high; the cap for undress is of blue cloth, flat topped, with patent leather visor, and red band lace half an inch wide. The helmet is of glazed leather with a front and rear visor, a brass-scaled chin strap, a brass Prussian eagle displayed in front, and terminates at the top in a brass-pointed spike about 2 in. high. The overcoat is long and of the same color as the pantaloons. In addition the men have for fatigue and drill common cotton pantaloons and short cloth jacket. The dress of officers is very similar to that of the privates; the texture of the cloth is better, and their rank is determined by a system of braids and shoulder straps; a sword like the cavalry sabre of the American service is worn. The Prussian soldier ready

* Including the troops of Hesse, Mecklenburg, &c.

for marching looks very much like the American under the same circumstances. His overcoat is made into a long slender roll and hung on the left shoulder, the two ends coming together, and being fastened on the right hip. His haversack of coarse white linen, and glass canteen covered with leather, are slung from the right shoulder. Around the flask are buckled two broad straps, used in peace to cover the sights of the gun. He wears no shoulder belt, but a pipe-clayed waist belt, on which are slipped two cartridge boxes of black leather, carried on either side, each box holding 20 cartridges. The knapsack is of calfskin, tanned with the hair on, and is slung by two pipe-clayed leather belts. The knapsack is made to keep its shape by a light wooden frame. On each end outside is a deep box in which is carried a case of 20 cartridges. On top of his knapsack is strapped a galvanized iron pot, holding about three quarts, with a tight-fitting cover, which is used separately for cooking. He wears on his waist belt a strong sword 15 in. long, which can be used for defence or for cutting wood or material for fascines and gabions. His gun is unburnished, so that it may not attract attention by flashing in the sun, and is pretty well coated with grease. He carries no blanket. A leather pouch for money is hung around the neck, and also a zinc plate attached to a card on which are engraved the soldier's regiment, company, and number. The whole weight of arms and equipments is 50 lbs.—The tactics used by the German infantry through the war of 1870 was an adaptation of the French tactics of the Napoleonic period. The ordonnance was issued in 1847 by the predecessor and brother of the present emperor; but certain modifications have been made, from the experience of the late war, which are embodied in the royal Prussian order dated March 19, 1873. (See article by Capt. Branckenburg in "United Service Magazine" for 1873, No. 74.) The Prussian system is now, or probably will be, the model for the rest of the world. The general theory is that every means must be adopted to increase the effect of fire on the enemy's troops and to diminish that effect on our own. The tactical formation up to a recent period had been based upon the fire of the Napoleonic era. This for the infantry was slow and very inaccurate, effective up to 200 or at most 250 yards; artillery fire was effective up to about 1,500 yards, but shell power comparatively feeble, the greatest effect being really within the case zone of 500 to 200 yards, before effective infantry fire was reached. Under these conditions we see French troops attacking in such formations as that of Macdonald's column at Wagram, consisting of three divisions, one of which had its battalions deployed in one great column, the others being in contiguous columns of battalions on the flanks; or as D'Erlon's columns at Waterloo, four divisions, each advancing in column on a front of a deployed battalion; or

as Ney's right column at Friedland, with a front of some 66 files and a depth of 80 ranks. The British troops used the line formation, at times two deep and at times four deep, in which latter formation both the guards and the 52^d regiment moved at Waterloo to repulse the last attack of the French imperial guard. Passing through the skirmishers, who ran in, they advanced over the comparatively short distance which separated the contending bodies of troops, and fired upon the enemy. The attack of Longstreet's corps on the left flank of the Union army at Gettysburg is also a case in point. Such a system of tactics would be utter suicide with the weapons of to-day; and the column of attack, which has played so famous a part in modern military history, may be said to belong to the past as completely as the Macedonian phalanx or the wooden line-of-battle ships. The Prussians now employ a system of opening engagements with heavy fire of artillery, then attacking with a cloud of skirmishers, who take advantage of every hollow in the ground, tree, fence, &c., followed by columns to supply gaps. This shooting line no longer merely covers the fighting line as before, but it is the fighting line. Fed by small bodies successively brought up in extended order, their places as supports being taken by fresh bodies drawn from the rear, the fighting line may be brought to great strength. Little by little it is fed by troops not in close formation; little by little it works its way up close to the enemy; and by this feeding system of the shooting line a superiority of infantry fire is established, and the enemy's troops are demoralized. When the final attack is made, this shooting line has become much stronger, for whole battalions may have been absorbed. It is a line, but not a rigid one, depending on conditions of ground, and one which has worked its way to this point in small bodies in fighting order, without that fearful loss and consequent demoralization which must inevitably attend the advance of a rigid line of anything like its strength. Then comes the final attack, the rush of this reënforced line, this fighting division closely followed by the nearest supports. The Prussian instructions thus describe it: "If the enemy's line appears to be shaken in its holding of any part of its position, the shooting line, with the nearest but hitherto concealed supports, rush forward in quick, concentrated assault on this point; while these draw together in close division, it must be the officers' endeavor to get them quickly in hand, in order to be able to resist the enemy's counter-attack. In the mean while, the divisions in rear follow up quickly." This system of fighting requires great intelligence, individual judgment, and at the same time thorough discipline and subordination on the part of the private soldier. It is secured in Prussia by the compulsory system of education, and by the elaborate character of the military training which every soldier is obliged to undergo.—*Russia*. The Russian

army is at present (1874) undergoing a complete reorganization, and trustworthy statistics concerning its present condition cannot be obtained. The following table is derived from official statistics for 1871:

RUSSIA IN EUROPE.

Besides the army of Russia in Europe, there are the army of the Caucasus, that of Turkistan, and that of Siberia. When the Russian army is completely reorganized it will consist in time of peace of about 750,000 men; in time of war the armies of Russia and the Caucasus will reach the number of 2,085,000 men. The proportion of artillery to infantry in the field will be about $3\frac{1}{2}$ guns to 1,000 men; there will also be one mitrailleuse to every $4\frac{1}{2}$ guns. The regiment is commanded by a major general in the guards and by a full colonel in the army. Each battalion has a lieutenant colonel at its head. The regimental staff consists of a regimental adjutant, a regimental quartermaster, a musketry instructor, and an officer in command of the non-combatant company. The non-commissioned staff consists of a drum major, a trumpet major, a sergeant major, three assistant sergeants, one or two chaplains, and non-combatant clerks, mechanics, &c. The battalion staff consists of a battalion adjutant, a battalion drum major, a battalion trumpet major, and an apothecary. A company has a captain, three lieutenants, and 211 non-commissioned officers and men on a war footing, as follows: 1 junker (candidate for admission), 4 senior sergeants, 12 junior sergeants, 20 lance corporals, 148 privates, 1 pay sergeant, 3 drummers, 3 buglers, 1 armorer sergeant, 12 privates in reserve, 1 apothecary, 1 assistant apothecary, 4 officers' servants. The Russian infantry has been armed with the Krinck converted rifle, but the Berdan breech-loader will shortly be issued to the whole army. The weapons are adjusted up to 600 yards, except those of rifle companies and eight picked shots in each com-

pany, whose sights are adjusted to 1,200 yards. Ninety rounds of ammunition are carried in the cartridge boxes; 40 more rounds are carried for each man in the company transports. Bayonets are always fixed. The weight of arms and equipments is 68 lbs., including three days' provisions. The infantryman has also a short sword. The uniform is gray; small shako hat; belts and straps white in the guard, except rifle companies; in the infantry of the line the belts are all black. The tactics are similar to those of the other great powers. The unit of administration in everything is the regiment. To make the infantry wholly independent of other arms, 10 men of each regiment are annually attached to the artillery, so there are always 80 men with eight years' service to help that arm in case of need. Eight men of each company carry intrenching tools, and are instructed in throwing up temporary works. There are schools in which the non-commissioned officers of the regiment are carefully trained, and they in turn teach the men. The standard is very high, and after their term of enlistment has expired they frequently decline commissions which they might obtain by passing a sufficiently high examination, and become schoolmasters and sometimes professors. The men receive but one new uniform a year. The companies make their own clothing entirely, even to the spinning of the braid. Army transportation is regimental; every company has a provision wagon with six days' rations, and a wagon with 40 rounds of ammunition to each man, with three horses driven abreast. Each regiment has an orderly wagon with lithographing press, &c., four ambulances, one hospital car, and one medicine cart; each brigade one band wagon, none in time of war. In some regiments the senior surgeon gives occasional lectures to the officers and men on the first steps to be taken when wounded in case skilled assistance is not at hand. Thus the regiment is an administrative unit, independent of extraneous aid. The private soldier is intelligent, though generally uneducated; but under the new system there will be a continual improvement.—*Austro-Hungarian Monarchy.* Military service is obligatory upon all citizens of Austro-Hungary, as in most other European nations. There are 36 divisions of infantry, each consisting of two brigades. Each regiment comprises in time of peace five battalions of four companies, with the skeleton of a supplementary battalion; in time of war, three battalions of four companies, two reserve battalions of four companies, and one supplementary battalion of five companies. The regiment of Tyrolese chasseurs has seven battalions of four companies, seven supplementary companies of reserve, and one supplementary battalion of seven companies in time of war. Each battalion of chasseurs has four companies, one company in reserve, and one supplementary company. The numbers in 1873 were as follows:

AUSTRIAN INFANTRY.

TROOPS.	PEACE FOOTING.		WAR FOOTING.	
	Batt.	Men.	Batt.	Men.
In the field. } Line.....	400	148,820	480	485,440
} Chasseurs.	40	21,451	41	58,753
Garrison, &c.....	..	8,315	..	16,215

} Hungarian.	86	9,244	126	150,220
Total.....	612	190,277	758	849,602

The battalion is commanded by a major or lieutenant colonel; its strength on a peace footing is 14 officers and 372 men. A company has 3 officers and 95 non-commissioned officers and men. On a war footing a battalion has 18 officers and 734 men—a company has 4 officers and 236 non-commissioned officers and men, 4 pioneers, and 3 bearers of wounded. The Austrian infantry is to be armed with the Werndl patent rifle, of which 400,000 had been issued in 1873. The proportion of artillery to the infantry is 3½ guns to 1,000 men. The uniform was formerly white; it is now bluish gray, with belts of untanned leather; close-fitting blue pantaloons, terminating in a boot. The tactics are undergoing a partial change, and will be made to conform with some modifications to the German method.—The infantry of the other powers of Europe is all modelled more or less upon the systems already described. The French army is undergoing a complete reorganization. The defeat of the French in the war of 1870 was due rather to bad generalship, faulty administration, and lack of preparation, than to any specific defect in the infantry. In France military service is obligatory upon every man except under certain definite conditions. The system of education is not so complete as in Germany. The English army is kept up by a system of volunteer recruiting; but there is a militia liable to service in time of war, in which all subjects from 18 to 60 years of age are enrolled. The regular infantry in Great Britain numbers about 60,000 men; in India about 45,958 men; in the other colonies 18,000 men. The term of service is 12 years. They are armed with the Henry-Martin breech-loading rifle. The infantry of the smaller states, in organization, tactics, weapons, &c., resembles that of the great powers. Of course it partakes of the characteristics of the different nations, and is efficient in proportion to the intelligence and discipline of the individual soldier. (See ARMY.)—Mounted infantry was largely employed during the civil war by the United States, and rendered important service. Under the command of Wilson in the west, it reached a degree of efficiency never before known; it possessed all the mobility of cavalry with the steadiness and dash of the best light infantry. It marched and manœuvred with cavalry, but fought habitually on foot, in a single line of skirmishers, with greater or less space between the files as

the circumstances of the ground and position of the enemy required. The successful use of mounted infantry gave rise to a necessity for the assimilation of the cavalry and infantry tactics, so that the commands, instruction, and manœuvres might be as much alike as possible. The new tactics prepared under the direction of Gen. Upton have just been issued to the army (1874), and seem to fully embody all that is required for handling large masses of cavalry or mounted infantry. In future wars the armies should have a much larger number of such troops, in order to secure the mobility or marching power of the horses, combined with the fighting power of the best infantry. That nation which first appreciates and applies this lesson on a large scale may confidently count upon results in actual warfare quite in proportion to the expense of the undertaking. (See CAVALRY.)

INFANT SCHOOLS. Pestalozzi was the first teacher of modern times who systematized infant instruction, and in the early part of the present century his system, improved and developed by later writers, reached its culminating point. Infant schools were established throughout Great Britain and the continent of Europe, and in every considerable town in the United States; but it was found after a few years' experience that these schools were doing more injury than good, and they have been generally abandoned. In 1837 an eminent German educator, Friedrich Froebel, introduced a new method of infant training, which is producing better results, and which obviates the difficulties and evils of the Pestalozzian system. He gave it the name of the *Kindergarten* (children's garden). This consists of a series of large, well ventilated, well lighted, and pleasant rooms, opening upon a garden, in which, besides the play ground for all, and a large garden plot, there are small plots for each child old enough to cultivate them. In the large garden are flowers, useful vegetables, and trees, and birds are encouraged to make it a home. The children may be from the age of two months to 14 years. They pass from three to five hours a day at the gardens. The infants are accompanied by their mothers or nurses, or, in default of these, are placed in charge of the teachers, young well educated women who enter into the work from a sincere love for it and for children. Froebel was very particular in the selection of teachers, deeming it indispensable to the success of the institution. Not more than 25 children should be under the care of a single teacher, and the elder children are of great assistance in carrying out the system. No corporal punishment is allowed; exclusion from a game, or from the gardens for a day or more, is the only punishment found necessary. Froebel devised many games and exercises for his course of instruction, and, as a part of the necessary apparatus, prepared his six gifts, which are used in all the kindergartens. In the use of each of these an explanatory song,

sung at first by the teacher, and afterward by the children, accompanies each exercise or game. The first gift consists of six soft balls of different colors, and a string; the colors are red, blue, and yellow—green, violet, and orange. They are moved horizontally, vertically, and in circles before the infant, by the teacher or an older child, who sings the song explaining the motions. By these balls the child obtains ideas of form, color, size, and movement, as well as of his own individuality. The second gift is a cube, a cylinder, a wooden ball, a stick, and a string; these are rolled, whirled, dragged, and used in a great variety of ways, and from them the child acquires ideas of form, size, sound, movement, and of development according to a fixed law. The third gift is a cube cut into eight equal cubes; these the child arranges into other forms, and receives new lessons in the law of development, gets a notion of angles, cubes, the laws of construction, and the division of units into halves, quarters, and eighths. He should always be taught to construct from the centre. The fourth gift is a cube divided into eight equal planes. In the use of this the children unite around a table, and construct together their buildings and other objects. By means of this and the preceding gifts, the alphabet and the elementary principles of arithmetic and geometry may be taught. The fifth gift is an extension of the third; the cube is divided into 27 small cubes, and three of these are divided diagonally into halves and three into quarters. This introduces the triangle, and gives scope for the construction of the arch and other architectural objects, and for practical perspective. The sixth gift is an extension of the fourth, the cube being divided into 27 planes, of which six are again divided, three in height and three in breadth; in the use of these the children are taught to build from the teacher's dictation. A seventh gift is added, containing all the forms of the last four. To these gifts are subsequently joined movable lines or plaiting sticks, which are also used for construction, being united when necessary by softened peas, pasteboard, and tissue paper, to be combined into figures and objects, and soft clay for modelling, in which many of the children become very expert. Drawing in the net, that is, on a slate furrowed into squares, and subsequently on paper ruled with a pale ink in squares, and painting in the net, are also introduced. The gymnastic exercises are still plays, of which there are a great variety, intended to develop all the muscles; these, too, are all accompanied by songs explanatory and instructive. For older pupils Froebel established scholars' gardens, in which workshops took the place of the games. During Froebel's life (he died in 1852) more than 50 kindergartens were established in Germany, Belgium, and Switzerland. Prussia, Saxony, and several of the minor states in Germany prohibited in 1851 the establishment of infant schools accord-

ing to Froebel's system, on the supposition that it inculcated socialism and atheism. But as it very soon became evident that kindergartens, according to Froebel's original principles, though apt to be misused for party purposes, could not really injure the state, the prohibitions were recalled, and the system was rapidly introduced everywhere. Though strenuous efforts were made in several states for the establishment of such institutions in connection with the public schools, no government has as yet acceded to the demand, and the benefits of the kindergartens continue to be restricted to those classes which are able to pay for them. There are in Germany several institutions for the education of teachers for these schools, and several periodicals are devoted to a further development of Froebel's ideas. The *Kindergarten und Elementarklasse*, published in Weimar since 1861, and the *Kindergarten*, published in Berlin since 1866, enjoy great favor. The system has been introduced into the United States, and there are several such schools in New York, Boston, Philadelphia, and elsewhere, especially in the western cities with a large German population.—See "Moral Culture of Infancy, and Kindergarten Guide," by Miss Elizabeth P. Peabody (revised ed., New York, 1869), and "The Kindergarten in Public Schools," by Adolf Douai (New York, 1870).

INFLAMMATION, a process which occurs in the progress of many diseases, and which is also produced by wounds and the presence of foreign bodies acting as irritants. There has always been considerable controversy as to the nature of inflammation, some regarding it strictly as a morbid process, although often accompanying restoration or healing, while others contend that it is essentially a natural and healing effort, the morbid conditions which may accompany it not being a part of the true inflammation, but the cause of it; in other words, that it is an attendant on that vital force which has so long been known under the name of *vis medicatrix nature*, being a conservative process employed by the nervous force which has been excited to action by a hurtful presence. Others again look upon the results of the process as determining whether it is morbid or healthful. Hippocrates regarded inflammation, like many of the symptoms of diseases, as a condition instituted by nature, or the *φύσις*, the essence or productive power of nature, for the purpose of restoration, and his practice was based upon this theory. Stahl, the elaborator of the phlogiston theory in chemistry, imagined an agent analogous to Hippocrates's *φύσις* dwelling in the human body, which he called *anima*, possessing a species of intelligence by which it could institute processes for the expulsion of hurtful intruders. Van Helmont had a similar theory, to which he added the necessity of two circumstances for the development of inflammation: the action of stimulants on parts having sensibility, and an increased activity of the arterial system, followed by redness, heat, swell-

ing, and pain in the parts. He compared the activity of the stimulus to that of a thorn, which gave alarm to the *archæus*, who immediately caused an increased flow of blood to set up a defence and a reparative process. Boerhaave attributed the swelling and obstruction to a change in the texture of the blood, which he maintained grew thicker and more viscid during inflammation, acquiring what he called a state of *lentor*. He supposed also that the increased action of the arteries forced larger particles of the blood into vessels too small to transmit them, constituting what was termed an *error loci*. Cullen, in place of the doctrine of *error loci*, proposed that of spasm and contraction of the capillary vessels, and taught that the system at the time possessed a peculiar condition, which he called *diathesis phlogistica*, consisting in an increased tone or contractility of the muscular fibres of the whole arterial system. Vacca, an Italian, about the middle of the 18th century, proposed a theory which was advocated by Mr. Allen of Edinburgh, and which contained an opposite idea, viz., that there was a want of tone or loss of power from which there arose a stagnation of the blood and a dilatation of the vessels of the part. John Hunter taught that the blood had a vitality of its own, and to support his doctrine cited the property of spontaneous coagulation. He says: "There is a circumstance attending accidental injury which does not belong to disease, viz., that the injury done has in all cases a tendency to produce both the disposition and the means of cure."—The general process of acute inflammation may be described as follows: If a translucent vascular membrane, as the web of a frog's foot, is sufficiently irritated by scratching it or pricking with a hot needle, there may be observed with the microscope a contraction of the capillary vessels, followed very soon by a dilatation. It is maintained by some that during the contraction the circulation is increased in rapidity, and that it is diminished during dilatation; while others maintain that the contrary action takes place in both cases, that is, that the circulation is slower in the first stage and faster in the second. This difference of opinion has arisen from not making the observations under precisely the same circumstances. When a capillary is enlarged throughout its whole length, the circulation will be for a short time more rapid than natural; and when it is constricted for a considerable distance, it will be slower; but if it be contracted in some places and dilated in others, the blood will move slower in the dilated places and faster in the contracted ones, as might naturally be expected from a consideration of ordinary hydraulic principles. After a time, however, the circulation in the dilated vessels becomes slower, and at the same time oscillating, and at last ceases, the vessel becoming distended with colored corpuscles. There is then an exudation of liquor sanguinis through the walls of the vessels, and occasionally, in

consequence of their rupture, extravasation of blood corpuscles takes place. The oscillation of the blood, which immediately precedes stagnation, has by some been attributed to arterial contraction and dilatation, while others have referred it to a rhythmical contraction and dilatation in the veins, which has been observed by Wharton Jones. In the natural circulation the colored corpuscles roll forward in the centre of the vessel, the space between them and the cell wall being occupied by the liquor sanguinis and a few lymph corpuscles. In young frogs the lymph corpuscles are numerous, and under irritation are said to increase and in that way impede the circulation; but in old frogs the same changes occur without the presence of lymph corpuscles. When stagnation or "stasis" takes place, it constitutes what is called the stage of congestion. If the morbid process continues the vessels may burst, or the liquor sanguinis may transude through the walls, without rupture, into the surrounding tissue. This constitutes exudation. The contraction of the capillaries in the first stage and their dilatation in the second are accounted for by supposing them to have the power possessed by involuntary muscular fibres, and John Hunter supposed that they possessed muscular power. It is known that they have permanent cell nuclei, similar to those of the involuntary muscular fibres of the intestines. Mr. Lister has found that fusiform cells, capable of contraction, are placed transversely around the vessels, which explains the fact that, like intestinal muscular fibres, they may be excited to contraction by mental emotions or by local applications. The recent observations by Claude Bernard and others of the effects produced by dividing the large sympathetic nerve trunk of the neck are cited by Dr. John Hughes Bennet as confirming the theory. It has been found that when innervation from whatever cause has taken place in a part, it is more prone to pass into the condition of inflammation. In regard to the four cardinal symptoms, as they have been termed, of heat, redness, swelling, and pain (the *rubor, calor, cum tumore et dolore* of Celsus), which were always enumerated by the older writers as constant, it has been found that some of the most fatal cases of inflammation are attended by only one or two of them, and in some cases not one of them has been present. The latent pneumonia of old people is thus graphically described by Dr. Bennet: "An old man may suddenly lose his appetite and strength; his respiration becomes hurried and feeble; his chest on examination is dull on percussion; mucous rattles are heard by the ear, and he dies. On opening his body gray hepatization has attacked the lungs, which are infiltrated with pus. He has from first to last had no pain; there has been no heat; on the contrary, the temperature was diminished; no redness nor swelling is anywhere detectable. Not only, therefore, are the cardinal symptoms

not characteristic of inflammation, but the idea that such is the case has led to the most mischievous results in practice." He maintains that irritation of texture, contraction or dilatation of the blood vessels, capillary hæmorrhage, serous effusion which constitutes dropsy, and stoppage of the sanguineous circulation, are only accompaniments of inflammation; and that its essential condition is exudation of liquor sanguinis. Dr. Alison observes that a precise notion of inflammation is obtained by including with the four cardinal symptoms a tendency to effusion of new products capable of assuming the form of coagulated lymph or purulent matter; but Dr. Bennet maintains that the tendency cannot be separated from the act itself, and that it is only when the exudation has taken place that there is proof that the tendency existed. The objection to this view is that inflammation may take place in non-vascular parts; to which Dr. Bennet replies that the changes which occur in these parts when irritated are widely different from those in vascular parts, and should not be confounded; and moreover, that what has been called parenchymatous inflammation is not true inflammation, which term should only be applied to that perverted action of the vascular tissues which produces an exudation of the liquor sanguinis, and that other results of irritation are simply congestion, or increased growth or hypertrophy. As to the terminations of inflammation, Dr. Bennet divides them into two, depending upon whether the exudation lives or dies. If it continues to live, it constitutes a molecular blastema, in which new growths, temporary or permanent, spring up according to the molecular law of development, such as pus and adhesive lymph. When, on the other hand, the exudation dies, three things may follow: 1, rapid death, with chemical decomposition, producing mortification or moist gangrene; 2, slow death, with disintegration of the tissues, causing ulceration; 3, what may be called a natural death, in which the exudation is broken down, liquefied, and absorbed, or in other words, resolution. When the exudation lives, it undergoes vital transformations which are greatly influenced by the condition of the system, whether it is healthy or diseased. In the healthy condition, when the exudation takes place on serous membranes, like the pleura, it has a strong tendency to form fibrous tissue; when it occurs on mucous membranes, or in areolar tissue, it is generally converted into pus corpuscles; when it occurs in dense parenchymatous organs, such as the brain, it has a granular development; and when it is poured out after wounds or injuries, the superficial portion is transformed into pus corpuscles, while the deeper seated is converted by means of nuclei and cells into nucleated and cell fibres, which ultimately form the cicatrix. The microscopic examination of a recent exudation of liquor sanguinis will reveal the appearance of bundles of minute filaments min-

gled with corpuscles. The filaments are formed by a simple precipitation of the molecules, like those which are developed in the buffy coat of the blood, and are from $\frac{1}{14.000}$ to $\frac{1}{16.000}$ of an inch in diameter. Bundles of them cross each other, and in time assume the appearance of dense fibrous tissue. The corpuscles at first are transparent, but soon become distinct, and are seen to be composed of a cell wall enclosing from three to eight granules. They vary in size from $\frac{1}{1300}$ to $\frac{1}{1000}$, and the granules from $\frac{1}{14.000}$ to $\frac{1}{16.000}$ of an inch in diameter, and are termed by Dr. Bennet plastic corpuscles. They are not pus, although Lebert called them pyoid, and it is generally believed that they are an intermediate or arrested stage of the degeneration of plastic lymph from its fibrillated development to pus. These plastic corpuscles after a time mostly disappear, some remaining in the form of permanent nuclei. After a time the surface of the exudation becomes villous, and loops of blood vessels penetrate the villi, by which the serum separating the surfaces is absorbed, so that they come together and unite, forming dense adhesions, which are often found in post-mortem examinations after inflammations of serous membranes. When the exudation takes place upon a mucous membrane, it may have the form of a fibrous mass, as in croup or diphtheria, but more often that of an opaque creamy fluid called pus. When it is poured into the meshes of the areolar tissue, or into the substance of the brain, it forms abscess. Pus corpuscles are of a globular form and yellowish color, varying from $\frac{1}{2000}$ to $\frac{1}{1200}$ of an inch in diameter. They are composed of a cell wall containing from two to five granules, which are about $\frac{1}{8000}$ of an inch in diameter. When a microscopic examination is made of a recently formed granulation on a healing wound, there will be observed around the looped extremities of the capillary vessels fibrous tissue in the process of formation containing plastic corpuscles, while pus corpuscles will be found developed on the surface. As the fibrous tissue becomes more dense the pus diminishes, and at last ceases, the fibrous tissue attaining a certain growth, and after a time contracting and forming a cicatrix. All pathologists agree very nearly as to the changes which are here described, but many, among them Virchow, Billroth, Simon, and Sir James Paget, believe that inflammation is not restricted to one act; that congestion and determination of blood may be considered its first stages; and that it may exist and pass away without exudation. They ask, if inflammation is produced by irritation, when this is in process of operation, where shall the dividing line be placed between the departure from health and the commencement of inflammation? It is also objected that the web of a frog's foot, as being a part of a cold-blooded animal, is not a proper subject for the experiment, and accordingly a bat's wing has been substituted. Sir James Paget

thinks that in warm-blooded animals stagnation will be found in only the most severely inflamed parts, while in the others retardation only exists. The difference of appearance in the red corpuscles in natural human blood and in that drawn during inflammation is worthy of notice. In healthy blood they have a tendency to run together in rows like a pile of coins tipped over, while in blood drawn during inflammation there is a tendency to run together in masses, leaving larger spaces of liquor sanguinis between them. According to present views, the effect of inflammation in recent wounds is not to promote direct healing, but to prevent it. When a fresh wound in a healthy person is closed and the blood forced out from between the cut surfaces, the severed capillaries unite directly, without, it is maintained, the exudation of plastic lymph; but if the lips of the wound are allowed to gape, an inflammatory action takes place, plastic lymph is poured out, and granulation follows in the manner above described.—The conservative action of inflammation may be observed in the healing of punctured or gun-shot wounds of the cavities of the body. When a puncture has been made into the abdomen, the great danger lies in the development of extending inflammation of the peritoneal membrane, and it is greatly increased if any of the contents of the intestines are poured into the space between its surfaces. The irritation produced by the injury excites adhesive inflammation between the different layers which compose the walls of the abdomen, and thus a simple channel is established between the exterior and interior, which in course of time may heal by granulation and suppuration. Severe cases of inflammation, as that which supervenes upon a compound fracture, are attended with marked characteristic symptoms. There is a feeling of heat, and of alternate heat and chilliness; the skin and mouth are dry; the pulse becomes rapid and the patient restless; the urine becomes scanty and more highly colored than natural, and great thirst is experienced; the tongue is dry and coated with a whitish fur; sleep is absent or greatly disturbed, and a degree of delirium comes on, more especially at night; there is usually constipation, but when the bowels act, which generally requires medicine, the excretions are very offensive; there is great swelling and tenseness of the tissues of the injured part, which when it subsides is attended with a remission of the constitutional symptoms; the skin and mouth become moist; the delirium and restlessness pass gradually away, and the patient sinks into a slumber.—The causes of inflammation are various, and may be divided into two classes, predisposing and exciting. The predisposing causes embrace constitutional and hereditary tendency, food, climate, season of the year, and habit of body. The exciting causes are poisonous substances, including the poisons of different diseases; irritants, such as cantharides, pepper, mustard;

caustic escharotics, strong acids, very hot and cold bodies, wounds, and also exposure of the person to wet and cold, or to sudden changes of temperature. Excessive mental excitation is a cause of inflammation of the brain. Inflammation may be acute or chronic. That which has been described is acute. After a subsidence of the intensity, if the action continues, in consequence of any source of irritation remaining, or from a want of tone of the parts, it becomes chronic, and from the latter cause the symptoms sometimes assume the chronic form from the outset. Inflammation is said to be healthy or unhealthy. If restoration takes place during the process, it is said to be healthy; but if there is wasting or destruction of tissue, as in ulceration or mortification, it is said to be unhealthy. It may also be common or specific; the latter term being employed to denote that which is caused by certain contagious poisons, such as smallpox, gonorrhœa, and erysipelas. It is sometimes called after the tissue in which it occurs, as mucous or serous inflammation. Inflammation of particular organs is usually designated by adding the termination *itis* to the anatomical name of the part affected, as laryngitis for inflammation of the larynx, gastritis for inflammation of the stomach, cerebritis for inflammation of the brain; but the old nomenclature is often retained, as pneumonia for pneumonitis, quinzy for tonsillitis. No nomenclature, however, is better than the employment of the word inflammation, together with the name of the organ or part inflamed. Inflammation is most likely to attack children under ten years of age, nearly one half of the mortality of the race occurring during these years. Inflammations of the pleura, brain, liver, and membranes of the heart are more frequent after the age of manhood. Spring is more favorable than any other season to the development of inflammation, and moist weather than dry, as is exemplified by the great rarity of inflammatory diseases in the regions bordering on the Pacific coast. The color acquired by an inflamed part differs with the degree of inflammation and the organ affected. The tendons and ligaments are seldom reddened. The fibrous membranes, like the pericardium, the dura mater, and the sclerotic coat of the eye, acquire a lilac or purple hue inclining to blue. The mucous membrane of the intestines first presents a bright red, but during the progress of the disease becomes a dark violet or a black, especially when passing into gangrene. These changes may be seen in the mucous membrane of the throat in an attack of malignant scarlet fever. In inflammation of the pleura and peritoneum (serous membrane) the color commences with a lilac, which afterward passes to scarlet, brownish, or violet. In the arachnoid, the serous membrane of the brain, the discoloration is slight, the chief sign of the inflammation being the serous effusion. The salivary glands assume a pink color, the kid-

neys a deep violet, and the lungs vary from a light rose to a deep purple. The alterations in color are owing in a great degree to the carbonization of the blood which is caused by stagnation and want of aëration. The continuance of inflammation in an organ prevents nourishment, and consequently after the swelling subsides it will be smaller. The wasting of the system during fever is an analogous example.—*Treatment.* This is divided into local and general. The local treatment of an inflamed wound consists in reducing the temperature by the application of cold or cool affusions, depending on the intensity of the action. Cold water may be allowed to drip from a vessel properly arranged and suspended above the wounded part, which is covered with a layer of linen; or cloths may be moistened with cool water and laid upon the wound; care in either case being taken to preserve an even temperature, and not by an intermission of the application to allow reaction to take place. The general treatment consists in a plain diet, principally of liquid food, which however should contain enough nourishment to support the strength of the patient; and he should be allowed to partake freely of water and cooling drinks, although at times warm drinks of weak tea may be allowed. To relieve constipation laxatives may be given. In inflammation of membranes and organs accompanying diseases such as pneumonia and like various forms of fever, contagious or not, there is almost always a want of saline constituents of the blood, the result of waste, and this condition may often be remedied by the administration of saline medicines, such as the bicarbonates of soda and potash. In fevers generally the parched condition of the mouth and throat and dryness of the skin are caused by a want of secretion of the mucous follicles and sudoriparous glands of the skin; and these alkaline salts in conjunction with the free administration of water are well calculated to restore a healthy action. Local bleeding by cupping and leeching may often be resorted to with benefit; but general bleeding, which was formerly practised to a great extent, is now almost wholly abandoned.

INFLUENZA. See BRONCHITIS, vol. iii., p. 312.

INFORMATION, in law, a written charge or accusation made against an alleged offender, stating some violation of law, before a court of competent jurisdiction to try the same. This process has taken the place of the ancient writ of *quo warranto*, and it is common to speak of it as an "information in the nature of a *quo warranto*." It is in substance, and to some extent in form, an indictment; but an indictment can be found only by a grand jury, whereas an information is filed by an attorney of the state or United States, or other competent law officer, at his own discretion. Informations are sometimes filed for public purposes; but more often, in the United States, by some private prosecutor, who uses the name of the

attorney general to ascertain his rights, or obtain redress for some wrong. Although criminal in form, they are in their nature civil proceedings. When moved by a private person for his own purposes, he is called "a relator," and the case is entitled "Information of A. B., attorney general, *ex relatione* of C. D. against E. F." But no such use of an information was known to the common law, as it springs altogether from statute provision; first, from the statute 9 Anne, ch. 20, and afterward by various state statutes in this country, and by adjudication founded upon the statute of Anne, in states in which there is no statute provision respecting it. The general purpose of informations is to inquire into alleged usurpations of, or intrusion into, or unlawful claim or exercise of official or corporate powers or franchises. Thus, they are often brought against banks, alleging that they unlawfully exercise banking privileges, when the real question is not whether they possess these powers or privileges, because they have been expressly conferred by the legislature, but whether they have not forfeited their charters by misconduct. So an information may issue against a medical school, to try its right of granting the degree of doctor of medicine with a corresponding diploma; or against the mayor of a city, to determine whether he has the right to admit freemen. The most important question is, how far informations will be granted to try questions which may be considered as of private right rather than public right. The court of king's bench refused to grant one against Sir William Lowther, to try the question whether he had the right to set up a warren, because it was of a private nature; and this principle has been applied with some severity in England. Here, however, informations are used very freely, to determine questions relating exclusively to private corporations, as banks, insurance companies, &c.; but in such cases the leave of the court to file the same is usually required. In general the court will not grant this leave where an adequate remedy at law is open to the relator; as where one sought an information against a turnpike corporation for going unlawfully through his land. The court will sometimes hear and decide the whole case on motion and argument; but if there be any question of fact, they will usually send the case to a jury. In general they will refuse an information, or determine otherwise against the relator, where there has been long and negligent delay, or persons from whom title is derived are dead, or persons having adverse title or interest have long acquiesced in the alleged usurpation. By statute in many of the United States an information is now substituted for an indictment; and where it is made use of, the rules governing indictments are applicable.

INFUSORIA, the name formerly given to numberless kinds of microscopic animalcules, the most minute of created beings, so called from

their being especially abundant in water infused with vegetable matter. From their exhibiting the simplest forms of animal life, they were grouped together under the division *protozoa*; but such a division, supposed to differ from all other animals in producing no eggs, does not exist in nature. Many are ascertained to be locomotive algae or seaweeds; others are acephalous mollusks, embryonic worms, or crustacea; they form favorite test objects for microscopes, and have been carefully studied by Bailey, Ehrenberg, and others. The majority may be classed among worms near the turbellarians or flat worms; they propagate by eggs, buds, or transverse fission, and some present the phenomena of alternate generation. (See ANIMALCULES.)

INGBERT, or *Sanet-Ingbert*, a town of Germany, in Rhenish Bavaria, near the Prussian border, on the Roorbach, 10 m. W. of Zweibrücken; pop. in 1871, 8,433. It is renowned for its coal and iron works.

INGELOW, Jean, an English poetess, born in Boston, Lincolnshire, in 1830. Her father was a banker, and a man of superior intellectual culture; her mother is of Scotch descent. As a child Jean was exceedingly shy and reserved, and she led a quiet, uneventful life till November, 1863, when the publication of her "Poems" secured her immediate recognition as a poetess of high rank. Several of the poems in this volume, especially "Divided," "High Tide on the Coast of Lincolnshire," and the "Songs of Seven," have become widely popular, and the last named (consisting of seven poems representing seven epochs in the life of woman) has been published separately and illustrated. Her subsequent publications are: "Studies for Stories" (1864); "Poor Matt" (1866); "Stories Told to a Child" (1866; 2d series, 1872); "A Story of Doom, and other Poems" (1867); "A Sister's Bye-Hours" (1868); "Mopsa the Fairy" (1869); "The Monitions of the Unseen, and Poems of Love and Childhood" (1870, published only in Boston, Mass.); and "Off the Skelligs," a novel (1872). In America her poems have reached a sale (in 1874) of 98,000 copies, and her prose works of 35,000. Miss Ingelow now resides in London. Three times a week she gives what she calls a "copyright dinner" to 12 needy persons just discharged from hospitals.

INGEMANN, Bernhard Severin, a Danish poet, born at Torkildstrup, on the island of Falster, May 28, 1789, died in Copenhagen, Feb. 24, 1862. He was the son of a clergyman, and was still at the university when he published a volume of poetry in 1811. After his return from his travels in Europe he became connected in 1822 with the academy of Sorø, of which he was a director from 1843 till its suspension in 1849. His most celebrated works are his epics *Waldemar de Store* and *Holger Danske*, his national anthem *Danebrog*, and his sacred songs. Many of his picturesque novels in relation to mediæval Denmark have been trans-

lated into English and other foreign languages. His complete works include dramatic poems (6 vols., 1843), historical poems and novels (12 vols., 1847-'51), tales and stories (12 vols., 1847-'56), and ballads, songs, and fables (9 vols., 1845-'64). His autobiography, edited by Galskjoet, appeared in 1862.

INGENHOUSZ, Johannes, a Dutch physician, born in Breda in 1730, died at Bowood, England, Sept. 7, 1799. In 1767 he went to London to learn the new mode of inoculation, and in the following year was sent to Vienna to inoculate the children of the imperial family, for which he was rewarded with the titles of aulic councillor and imperial physician, and a pension for life of £600. In 1776 he returned to England. Most of his essays were published in the "Philosophical Transactions."

INGERMANNLAND, or Ingria. See INGRANS.

INGERSOLL, a town of Oxford co., Ontario, Canada, on the Thames river and the Great Western railway, 85 m. W. S. W. of Toronto; pop. in 1871, 4,022. It has a large export trade in lumber and agricultural produce, and contains several grist and saw mills, manufactories of iron castings, machinery, woollens, wooden ware, cheese, &c., two branch banks, several hotels, two weekly newspapers, and churches of seven denominations.

INGERSOLL. I. Jared, an American lawyer, born in Connecticut in 1749, died in Philadelphia, Oct. 21, 1822. His father was appointed stampmaster general for New England in 1765, but was soon forced to resign, and in 1770 was appointed admiralty judge for Pennsylvania, and removed to Philadelphia. Jared graduated at Yale college in 1766, studied law for five years in London, spent a year and a half in Paris, and then returning to Philadelphia became almost immediately prominent in his profession. In 1787 he was one of the representatives of Pennsylvania in the convention which framed the constitution of the United States. He twice held the office of attorney general for the state, and was afterward United States district attorney for Pennsylvania. In 1812 he was the federal candidate for vice president of the United States. At the time of his death he was president judge of the district court of Philadelphia county. **II. Charles Jared**, an American statesman, son of the preceding, born in Philadelphia, Oct. 3, 1782, died there, Jan. 14, 1862. He studied law, became an attaché of Rufus King, minister to France, and travelled in Europe. On his return he published "Chiomara," a poem (1800), "Edwy and Elgiva," a tragedy (1801), and "Inchiquin the Jesuit's Letters," a political satire (1810). In 1813 he was elected to congress from Philadelphia, from 1815 to 1829 was United States district attorney, in 1837 was a member of the Pennsylvania constitutional convention, and served again in congress from 1841 to 1847, distinguishing himself as a democratic leader. He then received from President Polk the nomination of minister to France, but the sen-

ate refused to confirm it. His other chief works are "Julian," a dramatic poem (1831), and "Historical Sketch of the Second War between the United States and Great Britain" (4 vols. 8vo, 1845-'52). **III. Joseph Reed**, an American statesman and lawyer, brother of the preceding, born in Philadelphia, June 14, 1786, died there, Feb. 20, 1868. He graduated at Princeton college in 1804, studied law, and entered upon its practice in Philadelphia. In 1835-'7 he was a member of congress, but declined a reelection till 1841, when he was returned as a whig and protectionist, and held the office for four terms. From 1850 to 1853 he was minister to England. He was an able public speaker, and published several speeches and pamphlets, the principal one being "Secession a Folly and a Crime."

INGHAM, a S. county of the S. peninsula of Michigan, drained by the head waters of Grand river and by several smaller streams; area, 560 sq. m.; pop. in 1870, 25,268. It has a nearly level surface, timbered with sugar maple, beech, &c., and a fertile soil. Coal and iron ore have been found in the county. The Grand River Valley and the Jackson, Lansing, and Saginaw divisions of the Michigan Central railroad, the Lansing division of the Michigan Southern, the Detroit, Lansing, and Lake Michigan, and the Peninsular railroads traverse it. The chief productions in 1870 were 471,392 bushels of wheat, 382,164 of Indian corn, 233,594 of oats, 240,324 of potatoes, 281,562 lbs. of wool, 779,496 of butter, and 36,606 tons of hay. There were 5,954 horses, 6,535 milch cows, 1,200 working oxen, 8,138 other cattle, 62,407 sheep, and 11,491 swine; 24 manufactories of carriages, 4 of brick, 7 of clothing, 4 of cooperage, 12 of furniture, 6 of iron castings, 4 of machinery, 10 of saddlery and harness, 3 of sash, doors, and blinds, 6 of tin, copper, and sheet-iron ware, 1 of washing machines, &c., 1 of woollen goods, 3 planing mills, 28 saw mills, 4 breweries, 3 tanneries, 3 currying establishments, and 6 flour mills. Capital, Mason.

INGHAM, Charles C., an American painter, born in Dublin in 1797, died in New York, Dec. 10, 1863. He studied at the academy of Dublin, and obtained a prize for his "Death of Cleopatra." He settled in New York in 1817, and was one of the founders of the national academy of design, and its vice president from 1845 to 1850. Among his works, besides many female portraits, are "The Laughing Girl," "White Plume," "The Flower Girl," and "Day Dream."

INGHIRAMI, Tommaso, surnamed FEDRA, an Italian scholar, born in Volterra, Tuscany, in 1470, died in Rome, Sept. 6, 1516. He went to Rome when 13 years old. While he was acting the part of Phædra in Seneca's "Hippolytus," some of the machinery broke down, and he entertained the audience till the injury was repaired by the recitation of extempore Latin poetry. The multitude at once saluted him with the title of Fedra, and Alexander VI.

made him a canon of St. Peter's. In 1495 he accompanied the papal nuncio to the court of the emperor Maximilian, who created him count palatine and poet laureate. Julius II. appointed him librarian of the Vatican, and pontifical secretary. His works include a "Defence of Cicero," "Compendium of Roman History," and "Commentary on Horace."

INGLEBY, Clement Mansfield, an English author, born at Edgbaston, near Birmingham, Oct. 29, 1823. He graduated at Trinity college, Cambridge, in 1847, and was professor of logic and metaphysics at the Midland institute of Birmingham from 1855 to 1858, when he received the degree of LL. D. In 1870 he became foreign secretary to the royal society of literature. His principal works are: "Outlines of Theoretical Knowledge" (1856); "The Shakspeare Fabrications" (1859); "A Complete View of the Shakspeare Controversy" (1861); "The Still Lion" (1867); "An Introduction to Metaphysics" (1869); and "The Revival of Philosophy at Cambridge" (1870).

INGOLSTADT, a fortified town of Upper Bavaria, on the left bank of the Danube, at the confluence of the Schutter, 35 m. S. W. of Ratisbon, and the principal place between that city and Ulm; pop. in 1871, 13,164. It has one Protestant and several Catholic churches, two convents, a Latin and an industrial school, an ancient castle, a military hospital, and several breweries. The defences of the town were demolished by the French after a three months' siege in 1800, but were restored from 1827 to 1847 with all modern improvements of fortification. Its Roman Catholic university, founded in 1472, and long famous, was transferred in 1800 to Landshut. The first Jesuit college established in Germany was founded at Ingolstadt in 1555. In 1632 the town sustained a siege by Gustavus Adolphus.

INGRAHAM, Duncan Nathaniel, an American naval officer, born in Charleston, S. C., Dec. 6, 1802, died there, June 10, 1863. He entered the navy as midshipman in January, 1812, and became a captain Sept. 14, 1855. While in command of the sloop of war St. Louis in the Mediterranean, in July, 1853, he interfered at Smyrna with the detention by the Austrian consul of Martin Koszta, a Hungarian, who had declared in New York his intention of becoming an American citizen. This affair was elaborately discussed at Washington, between M. Hülsemann, the chargé d'affaires of Austria, and Mr. Marcy, secretary of state. The conduct of Capt. Ingraham was fully approved by the government, and congress by joint resolution, Aug. 4, 1854, requested the president to present him with a medal. In March, 1856, he was appointed chief of the bureau of ordnance and hydrography of the navy department. He resigned this post Feb. 4, 1861, and was made chief of ordnance, construction, and repair in the confederate army.

INGRAHAM, Joseph H., an American author, born in Portland, Me., in 1809, died in 1866.

After a brief experience of trade he became a teacher near Natchez, and in 1836 published "The South-West, by a Yankee." Subsequently he produced in rapid succession "La-fitte," "Burton, or the Sieges," "Captain Kyd," "The Dancing Feather," and other romances, some of which attained a large circulation. He finally became a minister of the Protestant Episcopal church, and was rector of a parish and of an academy for boys in Holly Springs, Miss. His last works were: "The Prince of the House of David" (1855), "The Pillar of Fire" (1859), and "The Throne of David."

INGRES, Jean Dominique Auguste, a French historical painter, born in Montauban, Sept. 15, 1781, died in Paris, Jan. 14, 1867. In the school of David he made such rapid progress that by the age of 20 he had gained in two successive years the first and second prizes of the academy of fine arts. After 1806 he passed nearly 20 years in Italy, abandoning the dry, classic style he had acquired from David. In 1829 he became director of the French academy in Rome. He was made a senator in 1862, and a member of the council of public instruction. His works are numerous, and comprise generally serious historical and classical subjects; in the great exhibition of 1855 at Paris an entire saloon was appropriated to them. His best known pictures are "Œdipus and the Sphinx," "Jupiter and Thetis," "A Woman in the Bath," "Ossian's Sleep," and "The Vow of Louis XIII." Many are in the Louvre, on the ceiling of one of the apartments of which is painted his "Apotheosis of Homer." His "Stratonice," painted for the duke of Orleans, was sold in 1853 for 40,000 francs. Among his latest works was the "Apotheosis of Napoleon I.," painted on the ceiling of the *hôtel de ville* in Paris. He painted the portraits of many distinguished personages, including Napoleon I.

INGRIANS, a tribe in the Russian government of St. Petersburg, belonging to the Tchudic branch of the Finns, now reduced to about 18,000, in 200 small and wretched villages. The Ingrians are poor and ignorant, but begin to assimilate more with the Russians; and many have forsaken the Protestant religion, which is that of the majority, for the Greek church. The Ingrians derive their name from the river Inger or Izhora. The strip of land between the Neva, the lake of Ladoga, the gulf of Finland, the Narva, and the governments of Pskov and Novgorod, was called Ingermannland or Ingria by the Swedes, who obtained possession of it at the beginning of the 17th century. Reconquered by Peter the Great in 1702, it has formed since 1783 the bulk of the government of St. Petersburg.

INGULPHUS, an English monk, born in London about 1080, died at the monastery of Croyland, Dec. 17, 1109. He was educated at Oxford, and attracted the attention of Editha, queen of Edward the Confessor, who became his patroness, and introduced him to William, duke of Normandy, who made the young Saxon

his secretary. He resigned that office in 1064, accompanied Sigfried, duke of Mentz, to the Holy Land, and became a monk in the abbey of Fontenelle, in Normandy, whence in 1076 he was invited to England by William, and appointed abbot of Croyland. The *Historia Monasterii Croylandensis*, from 664 to 1089, was long regarded as the work of Ingulphus, but Sir Francis Palgrave has proved it to be of a later age.

INHAMBAN, a town of East Africa, belonging to Portugal, near the mouth of the Inhamban river, N. of Cape Corrientes and 200 m. N. E. of Delagoa bay; pop. about 10,000. It has a harbor, and trades in beeswax and ivory.

INJUNCTION, a prohibitory writ. Courts of equity grant relief by injunction in those cases in which, but for their interposition, an equitable right would be infringed. In such cases courts of law can afford no remedy, for they cannot adjudicate upon an equity, and are powerless to prevent an invasion of it. Where then the rights of a party are wholly equitable in their nature, he can find no redress in the common law tribunals; but the mere existence of an equitable element in a suit being regarded by these courts as no bar to their procedure, they take jurisdiction, and, in deciding upon the legal merits of the case, must sometimes disregard the equity, because its recognition does not lie within their competence as courts of law. In such cases as these a court of equity, in the exercise of its distinctive jurisdiction, will interpose by injunction to protect the equity. This protection consists in restraining in behalf of the plaintiff the commission or continuance of some act of the defendant. An injunction is defined to be a writ, framed according to the circumstances of the case, commanding an act which the court regards as essential to justice, or restraining an act which it esteems contrary to equity and good conscience. As examples of those cases where relief is afforded to rights which either are wholly equitable, or under the circumstances of the case are incapable of being asserted in courts of law, may be cited instances in which trustees are enjoined from using their legal title to oust the possession of those who are equitably entitled to the benefit and enjoyment of the trust estate; so tenants for life or mortgageors in possession, who are not punishable at law for committing waste, will be enjoined in equity from doing so; and again, mortgageors in possession, though in some sense owners of the mortgaged estate, will yet be restrained by injunction from so reducing its value as to impair the security of the mortgagee. The administration and marshalling of assets, and the marshalling of securities, furnish other illustrations of the interposition of courts of equity by injunction to control the proceedings of creditors and others at law, and upon principles almost purely of an equitable nature.—A second class of cases includes those in which an equitable element is involved, but the matter of

which otherwise is cognizable at law. If in such cases the courts of law have already taken jurisdiction, a court of equity will in a proper case restrain their further procedure. Thus, when fraud, accident, or mistake has given one party to the suit an unfair advantage over his opponent, an equity arises in favor of the latter which will be protected by injunction. For example, if after judgment against the defendant at law a receipt is found, showing the payment of the very debt upon which he has been condemned, if there be no remedy in such a case at law, equity will enjoin, and so prevent, the execution of the judgment. Equity will also sometimes relieve against torts. The ground of interference here is, that between the complete right of the plaintiff and the largest remedy which he can receive at law for the wrong done him, there lies an equity which is not protected; this may rest either in the inadequacy of the money compensation which the plaintiff recovers, or in his right to be exempted from vexatious litigation. The equity jurisdiction in these cases is most frequently exercised in respect to waste, nuisances, and infringements of patent rights and of copyrights. The remedies at law in all these cases are similar. To cite alone that of nuisances, they can at most only abate or afford compensation for existing nuisances, but are ineffectual to prevent such as are threatened or in progress; if, however, the complainant's right be clearly admitted or established at law, and the nature of the threatened injury be such that it cannot be compensated by damages, or will occasion a constantly recurring grievance, equity has jurisdiction to enjoin. Further, as examples of the equitable relief afforded by injunction, it may be mentioned that courts of equity will restrain the unjust conveyance of real property or the transfer of stocks during the pendency of suits which concern them; they will forbid the publication of private papers, letters, or manuscripts; they will enjoin a husband's transfer of property in fraud of the legal or equitable rights of the wife; and will compel the due observance of personal covenants where there is no effectual remedy at law.—In the cases thus reviewed, the court of equity issues the injunction by its remedial writ. The judicial writ is in the nature of an execution, and issues subsequently to a decree of the court. Injunctions may be either temporary, when they are granted for a limited time, or until the filing of the defendant's answer, or the hearing of the court; or perpetual, when in the opinion of the court, after a hearing of the merits of the case, the plaintiff has established his right to such relief.

INK, the name given to a variety of preparations designed for producing colored letters in writing or printing. The ink of the ancients appears to have been similar to the solid Chinese or India ink—a combination of lampblack with glue or gum, in the proportions, as given by Dioscorides, of three parts of the former to one of the latter. The liquor of the cuttle fish

is also said by Cicero and Pliny to have been in use for ink. These preparations were used in a fluid state, by means of a style with a split point. Manuscripts written from the 5th to the 12th century are generally very legible, while those of the 15th and 16th centuries are made out with difficulty in consequence of the discoloration of the ink. This is owing in the one case to the permanent quality of the ancient inks, which were of the nature of a black paint, and also to the use of parchment and of a porous paper of cotton rags which absorbed the ink; and in the other to the closer quality of the linen paper of the later period, and the changeable nature of the ink, which was in fact a dye prepared from nutgalls and sulphate of iron. Paper bleached with excess of chlorine would cause this kind of ink to be discolored. The decay of the vegetable portion of the ink would cause the color to fade, and ancient writings thus rendered illegible have been restored by careful application of an infusion of galls. In an essay on the "Origin and Progress of Printing," privately printed by the Philobiblon society in England, 1859, it is said: "The ink of the ancients, and that used in the middle ages, had a consistency much thicker than that at present in use; very highly gummed when applied to papyrus, parchment, or paper, it formed letters in relief, as if they were embossed, which has given rise to an erroneous conjecture that these writings were produced by a sort of typographic process. Black ink was in general used for manuscripts and charters. The basis of all the black inks was carbon in various forms, as lampblack. Red ink was generally employed for writing initials and the titles of books and chapters; hence the term rubrics, from *rubrica*, red. At Orleans there is a charter of Philip I., dated 1090, written in green ink. The emperors signed in purple ink obtained from the *murex*; gold and silver inks were chiefly employed on colored parchments or purple vellum. The celebrated codex of Upsal is written with silver ink upon violet parchment, the initials and some passages being in gold."—Though the same materials were used for several centuries that are now employed for the best inks, little was known of the real nature of the compounds produced until the researches of Dr. Lewis and of Ribaucourt toward the close of the last century; the latter published an interesting paper containing an account of his observations in the *Annales de chimie* of 1798. The inks from that time were improved; but the recipes have until recently been objectionable from the introduction of unnecessary ingredients, and particularly from the necessity of employing much gum to prevent the coloring matter from subsiding; this renders the ink thick and indisposed to flow freely from the pen, and also liable to become mouldy. The requisites of a good writing ink are permanency of character, close adherence to the paper, a good color, no tendency to mould, and a proper consistency.

A combination of nutgalls with sulphate of iron was long the only suitable black solution known. The galls contain four vegetable substances, viz., gallic and tannic acids, mucilage, and extractive matter. The acids are regarded as more particularly necessary to a good ink, forming with the oxide of iron of the copperas a tanno-gallate of iron. Of the three causes of the deterioration of ink—mouldiness, the separation of the black coloring matter, and the change of color—Dr. Bostock, in an able paper in the "Transactions of the Society of Arts" for 1830, attributes the first to the mucilage, the second to the extractive matter, and the third to the tannin, which is disposed to decompose and thus involve the destruction of the compound of which it is an ingredient. The more nearly the ink approaches the composition of a gallate of iron, the more permanent he regards it. Several of the recipes require long exposure of the decoction of galls to the air, after this is obtained by boiling in water, the effect of which is to convert much of the tannin into gallic acid. Dr. Bostock recommends that the galls should be macerated for some hours in hot water, and the fluid filtered; the filtrate should then be exposed for two weeks to a warm atmosphere, when any fungoid growth that forms must be removed; and the infusion being made stronger than usually directed, no addition of mucilaginous substance will be required to give it a proper consistency. The solution of sulphate of iron should also be boiled or exposed some time to the air, which causes a portion of sesquioxide of iron to be formed, the presence of which is advantageous. The recipes for this class of ink alone are very numerous. That of Booth for a fine black ink is: Aleppo galls 12 lbs., sulphate of iron 4 lbs., gum arabic $3\frac{1}{2}$ lbs., water 18 gallons; the bruised galls to be exhausted by three successive boilings, each time with a reduced quantity of water; the decoction is strained, and while warm the solution of gum and copperas, also warm, is to be added, and the mixture is left for several weeks to deposit its sediment. A few drops of creosote added will prevent mouldiness.—Among the other kinds of ink, the following appear particularly worthy of notice. The blue ink first introduced by Mr. Henry Stephens of London, remarkable for a blue color which soon after drying changes to deep black, for perfect fluidity, and tenacious adherence to the paper, is a tanno-gallate of iron dissolved in sulphate of indigo, the coloring matter thus not being suspended as in the ordinary inks, but in complete solution. Another variety, also invented by Mr. Stephens, and remarkable for its tendency to fade by continued exposure to light, and to recover its hue when excluded from it, is made by submitting Prussian blue for two days or longer to the action of strong nitric or hydrochloric acid, then washing it well with water till all acid is removed, and finally dissolving it in oxalic acid. Hornung's recipe is to mix 4

parts of solution of perchloride of iron with 750 parts of water, and precipitate with 4 parts of cyanide of potassium in solution; the precipitate collected is washed with several additions of water, and allowed to drain until it weighs about 200 parts; it is then dissolved in one part of oxalic acid. Runge's ink, remarkable for its clearness and fitness for steel pens, which it does not corrode, is a cheap composition prepared by gradually adding one part of solution of chromate of potash to 1,000 parts of a strong cold decoction of logwood, 22 lbs. of logwood being boiled down with water to 14 gallons. The ink thus made is very black, and is not affected by weak acids, nor can it be washed out with water. It is, however, liable to become viscid and gelatinous. Dr. Normandy's indelible writing ink, which is remarkably permanent, is made by grinding 24 lbs. of Frankfort black with mucilage obtained by adding 20 lbs. of gum to 60 gallons of water, straining through a coarse flannel, then adding 4 lbs. of oxalic acid, and as much decoction of cochineal and sulphate of indigo as will give the required shade. Berzelius invented an ink which he regarded as the best writing ink known, and also nearly indelible; it is vanadic acid combined with ammonia and mixed with infusion of galls.—Copying inks, which are intended to give an impression of the writing made with them to a second or a third sheet moistened and pressed upon the original, are the ferro-gallic inks with a larger proportion of gum than they usually contain, and a portion besides of sugar or of sugar candy.—Red ink may be made by the recipe of Heusler, which is to boil 2 oz. of Brazil wood, $\frac{1}{2}$ oz. alum, and the same of crystals of tartar, in 16 oz. of pure water, till the water is reduced one half; in the strained liquor $\frac{1}{2}$ oz. of gum arabic is to be dissolved, and a tincture added made by digesting $1\frac{1}{2}$ dram of cochineal in $1\frac{1}{2}$ oz. of alcohol of specific gravity 0.839. Booth employs Brazil wood 2 oz., chloride of tin $\frac{1}{2}$ dram, gum arabic 1 dram, water 32 oz., and boils the whole down to 16 oz. Various recipes may be found for different colored inks, but there is little use for them. They are generally composed of coloring matter held in suspension by thickening the liquid with gum arabic. The nature of the Chinese or India ink has been already noticed. Proust says that lampblack purified by potash lye and mixed with a solution of refined glue, moulded and dried, makes a quality of this ink preferred by artists even to that of China. Until some recent discoveries it was supposed that this ink used with acidulated water was inattackable by chemical reagents that were not destructive to the paper.—The so-called indelible or marking inks were formerly altogether made by dissolving nitrate of silver in water and adding gum arabic and sap green, and were used in connection with a pounce, which was first applied to the linen on the spot to be marked. The pounce was an aque-

ous solution of carbonate of soda to which gum arabic was added. The best marking inks are now made by combining the two preparations at once, and bringing out the color after the application to the cloth by exposure to heat. A good ink is made by dissolving 7 parts of carbonate of soda in 12 of water, and adding 5 parts of gum arabic, then mixing with this 5 parts of nitrate of silver liquefied in 10 of ammonia; the mixture is to be gradually heated to ebullition in a flask, when it becomes very dark and of the proper consistence. Tartaric acid is sometimes advantageously employed to produce tartrate of silver, as by the following process: nitrate of silver is triturated in a mortar with an equivalent of desiccated tartaric acid; water added causes crystals of tartrate of silver to separate with liberation of nitric acid; this is neutralized by careful addition of ammonia, which also dissolves the tartrate of silver; the preparation is then thickened with gum, and coloring matter is added at pleasure. The Italian marking ink is terchloride of gold applied to cloth moistened with solution of chloride of tin. The subject of indelible inks will be further treated under NITRATES.—Sympathetic inks are preparations which when used for writing leave no visible, or at least only colorless, marks upon the paper. These are afterward brought out in colors by exposure to heat or to moisture, or by application of other substances. By the ancients it was known that new milk or the milky sap of plants might be so used, the writing with it being made visible by dusting over it a black powder. The property of writing made with the solution of acetate of lead to turn black by application of gaseous or liquid sulphuretted hydrogen was known in the 17th century, and ascribed to magnetic influences. The action was afterward styled sympathetic, and the name has continued to be applied to the various preparations of this nature. The materials of the common ferro-gallic inks may be used separately for a sympathetic ink, the writing being done with the sulphate of iron solution and washed over with that of the galls, as the writing of some old manuscripts is now occasionally restored. A dilute solution of chloride of copper used for writing is invisible until the paper is heated, when the letters are seen of a beautiful yellow, disappearing with the heat that developed them. The salts of cobalt, as the acetate, sulphate, nitrate, and chloride, possess a similar property, the letters appearing blue. The addition of a salt of nickel renders them green. The magic or chemical landscapes are made by the use of these metallic salts. The sky being painted with salt of cobalt alone, and foliage with the same mixed with nickel, the application of heat brings them out in their appropriate colors. A winter landscape, with the bare trees and ground covered with snow, may thus by accession of warmth be clothed with the green hues of summer.—Lithographers employ an ink for

tracing designs on paper, which are to be transferred to stone, composed of shell lac $1\frac{1}{2}$ oz., soap 2 oz., white wax 3 oz., tallow 1 oz., a strong solution of gum sandarach 3 tablespoonfuls, and lampblack; also an ink for taking impressions from engraved plates, which are to be transferred to stone, composed of tallow, wax, and soap, each 4 oz., shell lac 3 oz., gum mastic $2\frac{1}{2}$ oz., black pitch $1\frac{1}{2}$ oz., and lampblack.—Printing ink is a preparation very different from any of the inks used for other purposes; and its manufacture demands no little skill and experience. It should be of a soft adhesive character, readily attaching itself to the surface of the types, and as easily transferred to the paper pressed upon them, conveying in a clear tint the exact stamp. Thus spread in a thin film and pressed into the paper, it should quickly dry, and at the same time be so incorporated with the paper as not to be removable by mechanical means, while its composition insures for it durability and a power to resist the action of chemical agents as well as atmospheric influences. While disposed to dry readily on being applied to paper, it should retain its softness in the mass and while excluded from the air, and in this condition undergo no change. Its ingredients must not be of a corrosive nature to injure the rollers employed in spreading it. The appearance of good ink is glossy and somewhat oily; its texture smooth without grains; and its tenacity such as to cause it to adhere to the finger pressed against it, and yet leave but a short thread suspended from a portion taken out. The usual materials employed in its manufacture are linseed oil, rosin, and coloring matters. Rosin oil is largely used for some of the cheaper inks. For the best inks the linseed oil is selected of the purest quality, and this is clarified by digesting it for some hours with dilute sulphuric acid at a temperature of 212° , and then washing it with hot water; it will then dry much more quickly. The oil is then boiled, and the inflammable vapors that rise are ignited, and when they have burned a few minutes a cover is placed over the vessel, extinguishing the flame. The boiling is not stopped until a drop taken out and placed on a cold surface is covered with a film as it cools. A portion of rosin is then dissolved in the oil, the quantity depending on the degree of stiffness the ink may require; that for books and strong, stiff paper bearing more rosin, and receiving in consequence more gloss, than the ink for newspapers. The degree of viscosity given to the oil should also have reference to the use required of the ink. For letterpress printing soap should be added to the materials to enable the ink to be taken up clearly from the types without smearing. The best kind is yellow rosin soap, cut up into slices, dried, reduced to powder, and incorporated with the oil and rosin, or varnish, and before mixing placed again over the fire to expel any remaining moisture. Lampblack is almost universally

employed as the coloring matter; and much care is given in the manufacture of this article to obtain it of the very best quality. Other carbonaceous blacks reduced to impalpable powder are sometimes employed. For colored inks various pigments are introduced instead. The mixture is made with the hot compound of burnt oil and rosin in a cylindrical vessel, in which a revolving shaft with arms serves as a stirrer. From this the ink is drawn off, and is then ground in a mill until the ingredients are thoroughly incorporated. Various recipes may be found in Ure's "Dictionary" and Muspratt's "Chemistry" for printing inks of other materials than the above. For ancient processes see the work of Caneparius, *De Atramentis cujuscumque Generis* (Rotterdam, 1718).

INKBERRY, the popular name of *ilex glabra*, a shrub now placed in the same genus with the holly, but formerly known as *prinos glaber*. It is slender and rather graceful, usually 2 to 4

Inkberry (*Ilex glabra*).

ft. high, but sometimes much taller; its lanceolate or oblong leaves, sparingly toothed toward the apex, are an inch or more long, evergreen, leathery, shining on the upper surface, and of a fine dark green color; the small flowers are axillary, and the solitary fertile ones produce small black berries. It is found in sandy grounds along the coast from New England to Florida. It is deemed efficacious in intermittent fevers, but its chief use is for decoration. Its delicate brilliant green leaves, upon slender flexible stems, especially fit it for working in with flowers in bouquets. Quantities of it are sent from the southern counties of New Jersey to the New York florists, who keep it in good condition in a cool cellar for several months.

INKERMAN, a Russian village in the south of the Crimea, on the site of a ruined city, supposed to be the Ctenos mentioned by Strabo, at the head of the harbor of Sebastopol, and 35 m. S. S. W. of Simferopol. It stands at the

foot of a hill rising several hundred feet perpendicularly above the valley of the Tchernaya, crowned by massive walls and remains of towers. The side of the hill is pierced by numerous artificial caves, hewn from the solid rock, resembling the ruins found in Idumæa,

Monument at Inkerman.

but unlike any others in Europe. Near by is a church similarly constructed. The caves were probably made by the persecuted Arians, and were afterward occupied by Christian cenobites, as is shown by the paintings, chapels, and remains of altars found in them. On the heights of Inkerman, on the side of the valley opposite to the ruins, the Russians were defeated, Nov. 5, 1854, by the French and English. A monument to the memory of the fallen has been erected on the battle field.

INMAN, Henry, an American painter, born in Utica, N. Y., Oct. 20, 1801, died in New York, Jan. 17, 1846. He was preparing to enter the West Point academy when his taste for art led him to become a pupil of Jarvis the portrait painter, to whom he was apprenticed for seven years. Among his most characteristic portraits are those of Chief Justice Marshall, Bishop White, and Jacob Barker. He also painted landscape, *genre*, and history. In 1844 infirm health led him to visit England, where he was the guest of Wordsworth, whose portrait he painted, as well as those of Dr. Chalmers, Lord Chancellor Cottenham, and Macaulay. On his return to New York in 1845 he began a series of historical paintings for the national capitol. He was engaged upon one representing the cabin of Daniel Boone in the wilds of Kentucky at the time of his death.

INN (anc. *Enus*), a river of central Europe, one of the principal tributaries of the Danube. It rises in the Swiss canton of Grisons out of the small lake of Longhino, W. of Mount Bernina, at an elevation of nearly 7,000 ft. It crosses the Grisons frontier above the gorge of Finstermünz, enters Tyrol by a narrow valley,

and runs with great impetuosity through the northern district, particularly the Upper and Lower Inn valleys, to the border of S. E. Bavaria, which it crosses a few miles N. of the fortress of Kufstein. After a course N. and then E. for about 90 m. through Bavaria, it reaches Braunau on the Austrian frontier, whence it flows in a N. direction, forming the boundary between Bavaria and Austria, until it joins the Danube at Passau, after an entire course of 315 m. Navigation begins at Innsbruck, and becomes considerable below Hall. Steamboats ply on the Inn, and on its largest tributary the Salzach. The beautiful valley of the Engadine, which is situated near the sources and extends along the banks of the Inn, is also called the valley of the Upper Inn, where in the Romansh language, which is spoken by the inhabitants, the name of the river is On.

INN, according to judicial decision, "a house where the traveller is furnished with everything which he has occasion for while on his way." It is sometimes important to determine whether a house be an inn and the master an innkeeper, because of the legal rights, on the one hand, and on the other the peculiar and stringent liabilities, of an innkeeper. It is clear that while a sign is the usual and proper evidence that a house is an inn, it is neither essential to an inn nor the only evidence of it. A mere coffee house, or an eating room, is not an inn. Neither is a boarding house; but the distinction between a boarding house and an inn is not always easy, in fact or in law; and it is the more difficult, because the same house may be an inn as to some persons within it, and a boarding house as to others. The best test of this question we apprehend to be the transiency or the fixedness of the alleged guest. The old law constantly held that an inn is for the benefit *transientium*. By this is not meant that a guest of an inn loses his rights, or that the innkeeper loses his rights over him, if the guest remains a long time in the inn, provided he remains there as in an inn; and he does so, if he makes no contract, and comes under no obligation, to stay a moment longer than he chooses to. If he goes to an inn, occupies his room, and takes his meals, with the right at any moment of going away, and of paying for what he has had up to that moment, and nothing more, he continues to be a guest although he remain there a year or years. But if, upon going there, or at any time afterward, he makes a bargain by force of which he must stay at least so long, whether it be a week or a month, he is no longer a "transient person," and loses the peculiar character of a guest at an inn.

INNESS, George, an American landscape painter, born in Newburgh, N. Y., May 1, 1825. His parents removed to Newark, N. J., where he early learned drawing and the rudiments of oil painting. He has from his youth been subject to epilepsy, which has interfered materially with the consecutive pursuit of his art. When 16 years old he went to New York to study

engraving, but ill health obliged him to return home, where he continued to sketch and paint until his 20th year. He then passed a month in the studio of Regis Gignoux in New York, which is all the regular instruction he ever had. He made two visits to Europe, and resided for some time in Italy. For a number of years after his return he made his home near Boston, where some of his best pictures were painted. In 1862 he went to reside at Eagleswood, near Perth Amboy, N. J., and a few years later removed to New York. Inness is very unequal in his efforts, but lovers of nature find much to admire in his landscapes. He inclines to the French school in style, and has been compared not inaptly with Rousseau. A follower of Swedenborg, he deals largely in allegory, and uses the forms of nature to illustrate thought. Among his best pictures are "The Sign of Promise," "Peace and Plenty," "Going out of the Woods," "A Vision of Faith," "The Valley of the Shadow of Death," "The Apocalyptic Vision of the New Jerusalem and River of Life," "A Passing Storm," "Summer Afternoon," "Twilight," and "Light Triumphant." In 1870 he went with his family to Rome, where he still remains. To the national academy exhibition of 1874 he sent a picture entitled "Washing Day, near Perugia."

INNKEEPER. Public policy imposes upon an innkeeper a heavy responsibility. (See **BAILMENT**.) He is liable as an insurer of the property of his guests within his charge, against everything but the act of God or the public enemy, or the negligence or fraud of the owner of the property. He would therefore be liable for a loss caused by his own servants, by other guests, by robbery within or from without the house, burglary, riots, or mobs; for a mob is not a public enemy in this sense. It is however a good defence to the innkeeper, that his guest's loss was caused by the guest's servant or company, or by his negligence of any kind; or that the property was never in charge of the innkeeper because the guest had retained it in his own possession and under his own control. This last defence, however, is not made out by merely showing that the guest received and accepted a key of the room or of a closet, or that he exercised some preference and gave some directions as to where the property should be placed. But still an innkeeper may protect himself by requiring reasonable precautions from the guest. Thus, if he appoint a certain place of deposit for certain goods, as a safe for money or jewelry, with notice to his guests that he will not be responsible for their property of this kind if not put there, and a guest disregard this, the innkeeper is exonerated. But no especial delivery of the goods to the innkeeper is necessary to charge him, if they are in his custody in the usual manner. It is also held that he cannot refuse to receive a guest without good cause, as that his house is full, or that the guest is disorderly, or has infectious disease, or disreputable habits

or appearance. On the other hand, a guest has no right to select and insist upon a particular apartment, or put it to other purposes than those for which it was designed.—An innkeeper is of course liable like any other person for any loss or injury caused by his own default or negligence; and so a boarding-house keeper is liable to this extent. But an innkeeper is liable for the loss of or injury to property of a guest, without the innkeeper's own default of any kind. So, if he receive the horse and carriage of a guest, and put them under an open shed, away from his premises, or leave them in the open road, because he is crowded, and is accustomed to put them there when crowded, he is still liable for them as insurer. On the other hand, and perhaps as some compensation for these stringent liabilities, an innkeeper has a lien on the goods of his guest, for his charges against the guest; and he even has this lien on a horse or carriage, or other property stolen and brought to him by the thief. He has no lien on the person of the guest; and certainly none on the clothing actually at the time on his person. But the innkeeper's lien probably reaches all other property of the guest, and extends so far as to cover the whole amount due by the guest, for himself, his servants, or his animals. But where a person visits an inn by special invitation as a friend, or by general invitation as one of many, or as one of the public, on a certain day, without paying or being expected to pay anything, it has been held that the innkeeper is liable to the visitor only for losses or injuries caused by the innkeeper's own default or neglect.

INNOCENT, the name of 13 popes, of whom the following are the most important. **I. Saint**, born in Albano, died March 12, or, according to Baronius, July 28, 417. He succeeded Anastasius I., April 27, 402. On his accession he interceded without avail in behalf of the exiled John Chrysostom, and excommunicated Theophilus of Alexandria and other persecutors of the saint. The Donatists having been condemned by the council of Carthage (405), he persuaded the emperor Honorius to enact severe laws against them. On the invasion of Italy by Alaric at the head of the Visigoths, he tried to save Rome from these barbarians, and went to Ravenna to solicit the interference of the emperor; but during his absence the city was taken in August, 410, and plundered. After the departure of the Goths, Innocent returned to Rome and exerted himself to relieve the ruined metropolis. His zeal and charity endeared him to the Romans, heathen as well as Christian. He condemned the doctrines of Pelagius, who was supported by some Christians in the East, and evinced great severity against the Novatians, who were numerous in Italy. His feast is celebrated on July 28. Thirty letters attributed to him have been printed in Labbe's *Concilia*, vol. ii.; and Genadio, in his *De Scriptoribus Ecclesiasticis*, has given also as his a *Decretum Occidentalium et*

Orientalium Ecclesiis adversus Pelagianos datum, which was published by his successor, Zosimus I. **II. Gregorio de' Papi**, or **Papareschi**, born in Rome about 1090, died there in September, 1143. He was first a monk and afterward abbot of the convent of St. Nicholas, was made cardinal by Urban II., and appointed in 1124 legate to France by Calixtus II. His virtues, eloquence, and sweetness of temper secured him the affections of his colleagues; and on the death of Honorius II., before the event could be generally known, he was somewhat hastily proclaimed pope by 17 cardinals; but some of them who were dissatisfied met in the evening of the same day and gave their vote in behalf of Pietro di Leone, who assumed the appellation of Anacletus II. Pietro was possessed of immense wealth, which he lavished to make himself popular among the Romans. He was soon acknowledged all over Italy, while Innocent was obliged to take refuge in France. In an assembly of bishops at Liège, March 29, 1131, at which Lothaire II. of Germany was present, he declined the offer made by the latter to restore his authority in Rome, on condition of the pope's granting himself and his successors the right of investiture. Returning to France, Innocent secured the coöperation of St. Bernard, who accompanied him to Italy. There he was joined by Lothaire at the head of an army, whose services were rewarded by the temporary cession to that monarch of the provinces formerly belonging to the countess Matilda. After holding a council at Piacenza, Innocent reentered Rome with Lothaire May 1, 1133, and crowned him emperor in the church of St. John Lateran. Anacletus, however, still held possession of the castle of Sant' Angelo and several fortresses; he was also supported by Roger, king of Sicily; and Innocent was again driven from Rome, to which he did not return until the death of his opponent in 1138. He had now to negotiate for the abdication of Victor IV., another antipope who had succeeded Anacletus, and to secure the submission of the rebellious cardinals. He was then enabled to hold the second general council of Lateran, which was opened April 8, 1139, and attended by more than 1,000 bishops. But he was attacked by King Roger, and being taken prisoner could regain his liberty only by confirming this prince in the possession of Sicily and the title of king, which had been bestowed upon him in 1130 by Anacletus. Yielding to the entreaties of St. Bernard, he condemned in 1140 the opinions of Abélard; but soon becoming embroiled in a quarrel with Louis VII. of France, he put his kingdom under an interdict. This difficulty was not yet settled when the Romans, discontented with some of the pope's measures, and excited by the preaching of Arnold of Brescia, rose in arms against Innocent, and reestablished the senate and the tribunes of ancient Rome. The pope died soon after. Forty-three letters of Innocent II. are printed in Labbe's *Concilia*,

vol. x. **III. Giovanni Lotario Conti**, born at Anagni about 1161, died in Perugia, July 16, 1216. Being from his childhood destined for the church, he was sent to Paris to study theology, and then to the university of Bologna, where he mastered the science of law. He returned to Rome in 1181, and in 1190 was made cardinal deacon by his uncle, Pope Clement III. Being coldly treated by Celestine III., Clement's successor, he retired to Anagni, where he composed his treatise *De Contemptu Mundi, sive de Miseriis Humane Conditionis*. On the day that Celestine died, Jan. 8, 1198, although but 37 years old, he was unanimously chosen his successor by the college of cardinals. He reluctantly accepted the tiara; but as soon as he was firmly seated on his throne, he showed himself a worthy successor of Gregory VII. Aiming to establish the supremacy of papal power, he soon made his influence felt in nearly every part of Christendom. His first care was to restore order in the administration of the city of Rome, by forcing into submission such civil officers as had hitherto sworn allegiance to the emperor; he then extended his authority over the cities of central Italy which had been usurped by vassals of the empire, and, while vindicating his political rights, appeared as the champion of justice, humanity, and morality. Philip Augustus of France having repudiated his wife Ingeburga of Denmark to marry Agnes of Meran, Innocent excommunicated him in 1199, and put his kingdom under an interdict. After resisting for eight months, the king yielded to the pontifical authority, dismissed his new queen, and took back the Danish princess. Innocent had previously been instrumental in bringing about a five years' truce between Philip Augustus and Richard I. of England. About the same time he was appointed guardian of young Frederick of Hohenstaufen, the son of the late emperor Henry VI., and of Constanza, queen of Naples and Sicily; but he refused Frederick the investiture of his kingdom of Sicily until he had set at liberty Queen Sibyl, her daughter, and her son William, who had been imprisoned by Henry VI. He was soon called to interfere in the political affairs of Germany. Philip of Swabia and Otho of Brunswick were now contending for the imperial crown. Innocent, after trying in vain to bring about a pacification between the rivals, took the part of the latter, who nevertheless was unable to stand his ground, and was obliged to take refuge in England. Meanwhile the pope had increased his power in Italy, and concluded with the cities of Lombardy an alliance against Philip of Swabia, by which he was enabled to reappear as a mediator; he proposed a compromise, leaving Philip in undisputed right to the imperial crown, and declaring Otho his successor. This agreement had scarcely been entered into when the emperor was murdered by one of his followers. Otho was immediately acknowledged by most of the German princes, and in

1209 proceeded to Rome, where he received the imperial crown at the hands of the pope. But the new emperor soon showed signs of determined hostility to the power of the pope, seized upon several cities of central Italy, and claimed Naples and Sicily as fiefs of the empire. Innocent at once excommunicated him, called for the assistance of France, and summoned the electors to choose another emperor. They deposed Otho in 1212, and elected Frederick, king of Naples and Sicily. Innocent acted also a conspicuous part in the events which marked the latter part of King John's reign in England. The election of Stephen Langton to the archbishopric of Canterbury, supported by the pope and opposed by the king, was the cause of a protracted dispute, in the course of which John, resorting to violent and even cruel measures, saw his kingdom placed under an interdict, and himself excommunicated, and finally deposed by the pope, Philip Augustus being directed to put the sentence into execution. John, frightened into submission, complied with the humiliating terms which were dictated to him by the pope's legate, and put his dominions under the protection of the Roman see (1213). Innocent immediately commanded the king of France to desist from the attack upon England, which belonged to the church; thenceforth taking up the cause of his vassal, he supported him in his contest against his revolted subjects and the attacks of Louis of France, the son of Philip Augustus, but could not prevent his being driven out of England. His zeal in maintaining the sanctity of marriage was also displayed in the case of Alfonso IX., king of Leon and Castile, who had taken to wife his own niece, a daughter of Sancho I. of Portugal. As both princes resisted the repeated remonstrances of the pope, he laid their kingdoms under an interdict and themselves under the ban of excommunication, until the scandal ceased. Afterward he united these sovereigns and the kings of Aragon and Navarre in a crusade against the Moors, which resulted in the victory of Navas de Tolosa, July 16, 1212. Pedro II. of Aragon was crowned in Rome by Innocent, to whom he did homage for his dominions; and the title of king was conferred on Leo of Armenia, Premislas of Bohemia, and Joannicus prince of the Bulgarians. In Norway Sverrer the Great had baffled all the efforts made by the legates of Celestine III. to check his tyranny. Innocent, being appealed to by the king and his nobles, after hearing both parties, excommunicated Sverrer, and released his subjects from their allegiance. One of his first undertakings after his election had been to preach and organize the fourth crusade. Its failure arose from the violation of the oath imposed by him on its chiefs not to make war on any Christian power. He displayed the most uncompromising severity against heresy, the extirpation of which was with him a matter at once of duty and policy; this led him to sanction the crusade against

the Albigenses, which was carried on by his legates and Simon de Montfort with such rigor and cruelty as finally to draw his censure upon them. After being for 18 years the ruling spirit of his age, he was carried off by a violent fever which terminated in paralysis. Innocent's works (Cologne, 1552 and 1575; Venice, 1578) consist of theological discourses, homilies, a commentary on the seven penitential psalms, and a number of letters. His letters, which are the most important in a historical point of view, were printed by Baluze in 2 vols. fol. (Paris, 1682), to which Bréguigny and Du Theil in 1791 added 2 vols. containing new letters collected from the Vatican archives. Innocent is the author of a celebrated hymn, *Veni Sancte Spiritus*. The *Stabat Mater*, which is also attributed to him, is claimed as the work of a Franciscan. The German historian F. Hurter has published a remarkable history of this pope: *Geschichte Papst Innocenz III. und seiner Zeitgenossen* (4 vols. 8vo, Hamburg and Gotha, 1834-'42). See also his life by A. É. de Gasparin (Paris, 1873). **IV. Innocent XI., Benedetto Odescalchi**, born in Como, May 16, 1611, died in Rome, Aug. 12, 1689. Historians have confounded him with a namesake and relative, who was a soldier in his youth, but embraced the ecclesiastical profession. Benedetto was descended from a wealthy family, began his studies in the Jesuit college of Como, and graduated in theology and canon law at Rome, where he received holy orders. He was made cardinal by Innocent X. His virtues and talents secured him general esteem; and on his accession to the papal throne, he applied himself to revive the ancient discipline of the church. He attempted to curtail the right of asylum, which, being possessed by foreign ambassadors, had extended to the entire districts where their residence was situated. His good intentions were partly baffled by the opposition of Marshal d'Éstrées, the French ambassador; but he was prudent enough to avoid at the time an open rupture with Louis XIV. The domineering spirit of the king soon gave rise to a quarrel. In 1673 a decree of Louis ordered the *regale*, that is, the royal privilege of receiving the revenues and granting at pleasure the benefices of vacant bishoprics, to be extended over the provinces of France in which it had not yet been in existence; this was opposed by the bishops of Alet and Pamiers, whom the pope earnestly supported. The king then summoned a general assembly of the bishops of his kingdom, who not only supported his policy concerning the *regale*, but issued the celebrated propositions of March, 1682, declaring the power of the pope inferior to that of a general council, and maintaining the special rights and privileges of the Gallican church. In answer to this Innocent held a solemn consistory, severely censured the bishops who had taken part in the proceedings, which a bull declared null and void, ordered the four propositions to be burned, and refused to grant

canonical confirmation to such bishops as had been newly appointed by the king. This contest was embittered by the renewal of the quarrel about the right of asylum. By a brief of May 12, 1687, Innocent formally abolished that right, and excommunicated all who should maintain it. Louis XIV. at once gave orders to his new ambassador, the marquis de Lavaradin, to uphold the disputed privilege, even by force; and the marquis accordingly made a solemn and threatening entrance into Rome at the head of about 800 armed men. The pope, considering him excommunicated *de facto*, declined to receive him, and ordered worship to be discontinued wherever he should present himself. The king, exasperated at the pope's firmness, caused his parliament and a number of French bishops to appeal to a general council against Innocent's measures, had his nuncio arrested at Paris, and seized upon Avignon. The pope continued inflexible to the last. It was during his pontificate that Michael Molinos, a Spanish priest, advanced in his "Spiritual Guide" the mystical doctrine known as quietism. The book was condemned by the inquisition, Sept. 3, 1687; the author abjured his doctrine publicly; and the proceedings were approved by the pope. In 1688 he received an embassy from the king of Siam, who had been converted by Jesuit missionaries. Some historians have affirmed that the Jesuits accused Innocent XI. of Jansenism; this the Jesuits deny, and there exists no evidence of the accusation. His repeated entreaties induced John Sobieski to relieve Vienna in September, 1683, when besieged by the Turks; the pope and the cardinals contributing a subsidy of 400,000 crowns for the expenses of the war.

INNS OF COURT, colleges in London, in which students of law reside and pursue their studies. In England at a very early date the science of law was taught in the metropolis in certain buildings in the immediate vicinity of the courts of law which were called inns of court, inn anciently signifying a mansion or place. The establishment of the court of common pleas at Westminster led to the gathering in its neighborhood of the whole body of "common" lawyers, and to the establishment in the metropolis of hostels or *hospitia curiæ*, which were so called because they were attached to or dependent upon the court. These hostels were occupied by the lawyers as offices and sometimes as dwellings, and contained also schools where the law was studied. But in 1346 the knights hospitallers of St. John of Jerusalem, to whom the pope had granted the English estates of the suppressed order of knights templars, leased the buildings and gardens of the templars in London to certain students of the common law, who established in them a hostel or inn of court. The place continued to be called the Temple, from its former occupants. In the course of a few years the number of inns increased to four, which still exist, viz.: the Inner Temple, the Middle Temple,

Lincoln's Inn, and Gray's Inn, each of which contained 200 members. Stow, in his "Survey of London" (1598), says of the lawyers who occupied these inns: "These societies are no corporations, nor have any judicial power over their members, but have certain orders among themselves which by consent have the force of laws. For slight offences they are only excommunicated, that is, put out of commons, which is, not to eat with the rest in their halls; and for greater, they lose their chambers, and are expelled the house; and being once expelled, they are not to be admitted by any of the other three societies. The gentlemen in these societies may be divided into four ranks: 1, benchers; 2, utter benchers; 3, inner barristers; 4, students." In course of time two bodies were formed, called the "Honorable Society of the Inner Temple" and the "Honorable Society of the Middle Temple," who held their buildings as tenants of the knights hospitallers until the suppression of monastic bodies by Henry VIII., after which they held them of the crown by lease. In 1608 the buildings of the two temples were granted by letters patent of James I. to the chancellor of the exchequer, the recorder of London, and the benchers and treasurers of the Inner and Middle Temples, for "lodging, reception, and education of the professors and students of the laws;" and it is by virtue of these grants that they are still held by an incorporated society of the "students and practisers of the laws of England." The Temple garden, which lies between Whitefriars and Essex street, has been celebrated by Charles

Lamb and Leigh Hunt, and was much frequented as a pleasure walk during the 17th and 18th centuries. In the hall of the Inner Temple, a noble room ornamented with emblematical paintings by Sir James Thornhill, and by portraits of Littleton and Coke, dinner is prepared for the members of the inn every day during term time. Students of law must keep 12 terms, that is, five years, at the inns of court before they are entitled to be called to the bar, and those of the Inner Temple are required to dine in this hall at least four times in each term. On certain "grand days" the judges, the masters in chancery, and many of the leading lawyers of England dine here, together with a large assemblage of the students. Formerly the Inner Temple was celebrated for the magnificence of its entertainments and revels,

especially in the 16th and 17th centuries. The hall of the Middle Temple, the largest and finest of the old inns of court, was built in 1562-'72. It is ornamented by elaborate carvings, by portraits and busts, and by the coats of arms of Somers, Hardwicke, Cowper, Thur-

Middle Temple Hall.

low, Dunning, Eldon, Blackstone, Stowell, Tenterden, Curran, and many other eminent lawyers, formerly members of the society, emblazoned on its windows. Lincoln's Inn, the next in importance to the Inner and Middle Temples, is on the W. side of Chancery lane,

Inner Temple Hall and Library.

and derives its name from being on the site of the palace of an earl of Lincoln who died there in 1310, and by whom the land was assigned to certain professors of the law for the establishment of an inn of court. The hall and library, designed by Hardwick, and finished

in 1845, form one of the noblest piles of building in London. The chambers of this inn are chiefly occupied by chancery barristers, conveyancers, and persons in attendance on the court of chancery, which court is held in its hall. Attached to the inn are extensive gardens, celebrated in the "Tatler," No. 100. Gray's Inn, the fourth inn of court in importance and size, is named from the lords Gray of Wilton, whose residence it originally was. It is in Gray's Inn lane, and has a garden which appears to have been planted with elm trees in 1600 under the direction of Francis Bacon, at that time treasurer of the society. The hall is a very handsome room, built in 1560. Its windows are emblazoned with the armorial bearings of Lord Bacon, Sir Nicholas Bacon, Lord Burleigh, and other eminent members.—Each of the inns of court forms an independent society, but they all agree in the observance of certain common regulations. No person can keep a term in any of them without being in the hall on three days when the grace is said after dinner. None of the societies can call a gentleman to the bar before he has been five years a member of the society, unless he is a master of arts or a bachelor of laws of the university of Oxford, Cambridge, or Dublin. No person in trade or in deacon's orders, and no one who has held the situation of a conveyancer's clerk, can be admitted at all; and solicitors and attorneys must have their names struck off the rolls for two years, and the articles of clerks must be expired or cancelled two years, before they can be admitted. An applicant rejected by one society will not be admitted by any other. On his admission the student pays various fees amounting to £30 or £40, and enters into a bond of £100 for the payment of his commons or dinners while a student. On the expiration of his terms he addresses a petition to the benchers at a special council; and if they approve, he waits upon them after dinner, the oaths are administered, and he is called to the bar. The dues for admission vary in the different inns from £66 in Gray's Inn to £93 in Lincoln's Inn. There are different degrees among the

members of the inns. The sergeants are the highest degree at common law, as the doctors are in civil law. Queen's counsel is another rank, admission to which is technically called giving a silk gown, the costume of the bearers of this honor. The benchers of the inns are elected from the barristers at the bar according to seniority. They govern the society, and may reject an application for admission without assigning a reason.—The four great inns of court have attached to them inns of chancery, of which the Inner Temple has two, Clement's and Clifford's (formerly also Lyon's, now the Globe theatre); the Middle Temple one, New Inn; Lincoln's Inn one, Thavies's; and Gray's Inn two, Barnard's and Staples's. Two others, Furnival's and the Strand, no longer exist. These inns are principally inhabited by attorneys.

INNSBRUCK (Ger. *Innsbruck*), a city of Austria, capital of Tyrol, on both sides of the Inn, near its junction with the Sill, 245 m. W. S. W. of Vienna; pop. in 1869, 16,810. The name, meaning Inn bridge, is the equivalent of that given to the locality by the Romans, *Enipontum*; there are now several bridges. The town is surrounded by steep mountains 6,000 to 9,000 ft high, and is well built, especially

Innsbruck.

on the right bank of the Inn. The finest street is the Neustätterstrasse, in which are the buildings where the Tyrolese estates hold their sittings, the post office, and a triumphal arch

erected by Maria Theresa. The Franciscan church (*Hofkirche*) contains one of the most splendid monuments of Europe, that of Maximilian I. (who ordered its construction, with a sepulchre for his own remains, but is buried in Neustadt, near Vienna). On each side of the aisle stands a row of tall figures, 28 in number, representing principally the most distinguished members of the house of Austria. The sarcophagus is ornamented with 24 representations of the principal political and domestic events in the life of Maximilian, sculptured in alto rilievo by Alexander Colin of Mechlin. In the same church is the Silver Lady chapel, so called after a silver statue of the Virgin, containing the mausoleums of the archduke Ferdinand and of his wife Philippine, which are also attributed to the genius of Colin, whose own tomb, said to be the work of his own hands, is in the cemetery of Innsbruck. The tomb of Andreas Hofer is in this chapel. In this church Christina of Sweden made her public renunciation of Lutheranism. There are altogether 11 churches, among which are the Capuchin church with the penitential cell of Maximilian II., and the St. James church, noticeable for its rich decorations. Among the other public buildings are the palace built for Maria Theresa, with an equestrian statue of Archduke Leopold V. in the courtyard, and a large edifice in the city square (*Stadtplatz*), once the residence of the counts of Tyrol, now a private dwelling, with a famous oriel window, covered with a golden roof (*das goldene Dachl*), built in the 15th century, at a cost of 30,000 ducats. The chief educational establishment is the Roman Catholic university, which was founded in 1672 by the emperor Leopold I. In 1873 it had 46 professors and 663 students, fully one third of whom are under the theological faculty, the professors of which are Jesuits. In consequence of the remonstrance of the liberal party in Austria and of a majority of the professors of the university against the privileged position of the Jesuits, the minister of public instruction in July, 1872, deprived the theological faculty of the right of electing a member of the academic senate, and, alternately with the other faculties, the rector of the university. In 1873 the right was restored to the Jesuits, provided the professors should individually qualify for their office like the professors of the other faculties. The library of the university has about 50,000 volumes. There are also a gymnasium, a commercial school, and a national museum founded in 1823, with rich collections of antiquities and works of art. The principal manufactures of the town are silks, ribbons, gloves, calico, and glass.—In 1234 Innsbruck was clothed with the privileges of a town by Otho I., duke of Meran. It subsequently became the residence of the Austrian archdukes, and its most prosperous period was in the early part of the 17th century, when Ferdinand II. held his brilliant court there. It was taken by the Bavarians in 1703, but was soon

recovered by the Austrians. In 1809 it suffered much during the war in Tyrol. After the second revolutionary outbreak in Vienna in 1848, the emperor Ferdinand fled to Innsbruck, and resided there for several months.

INO, in Greek mythology, a daughter of Cadmus and Harmonia. By command of Juno, Athamas, king of Orchomenus, had married Nephele, by whom he was father of Phrixus and Helle; but he was also secretly wedded to Ino, by whom he had Learchus and Melicertes. Hating the children of her rival, Ino persuaded her husband that the gods were angry with him, and could only be appeased by the sacrifice of Phrixus and Helle. Nephele rescued the children, and Mercury punished Ino by giving her the young Bacchus to nurse, which brought down on her and her husband the anger of Juno. Athamas was driven mad, and in this state killed his son Learchus; while Ino, flying for safety with Melicertes in her arms, leaped into the sea. Neptune changed her into a sea goddess, giving her the name of Leucothea, while Melicertes became Palæmon. There are wide variations in the traditions concerning Ino. Æschylus, Sophocles, Euripides, and Achaus have used her story in their tragedies.

INOCULATION, the transmission of a disease from one individual to another by means of a morbid matter taken from the body of the first and introduced into the system of the second. The morbid matter may be introduced directly into the tissues by means of an incision or puncture in the skin, or it may be applied in a fluid form to an abraded surface, from which it is absorbed by the skin itself. There are only certain diseases which are communicable in this way, the simple inflammations and their products not having the power to breed a similar malady in a healthy person. But there are particular specific diseases, such as smallpox, cowpox, primary syphilitic and gonorrhœal inflammations, and the like, the exudations of which are charged with a peculiar organic virus which when introduced into the system of another individual gives rise to a disorder like that by which it was originally produced. Vaccination is simply the inoculation of vaccina or cowpox; and the term inoculation is sometimes restricted in common parlance to the intentional communication, by this means, of smallpox in its original form. The inoculation of smallpox was early found to mitigate the severity of the disease; but vaccination was afterward substituted for it (see JENNER), because vaccina, though milder still, was discovered to be an effectual protection against smallpox itself.

INOWRACLAW, or *Jung-Breslau*, a town of Prussia, in the province of Posen, 24 m. S. E. of Bromberg; pop. in 1872, 7,429, including over 3,000 Jews. It contains a Roman Catholic and a Protestant church, a synagogue, and large saltpetre works. An extensive deposit of mineral salt was discovered there in 1871.

INQUISITION, or **Holy Office**, a tribunal established in various Roman Catholic countries to search out and to try persons accused of heresy, as well as certain other offences against morality or the canons of the church. The first formal sanction of the inquisition by a papal bull was in the 13th century; but long before that heresy had been declared a crime, and inquisitors, or inquirers after heretics, had been appointed by Christian princes. Constantine the Great, the first emperor who made Christianity a state religion, made heresy a state offence, and repeatedly banished those who refused submission to his decisions in doctrinal controversies. Athanasius, the defender of orthodoxy, and Arius shared in turn the same fate. Under him and his sons commissions were also issued against the Donatists, who were visited with the most rigorous punishment. The terms "inquisition" and "inquisitors" appear for the first time in history in connection with the searching out and punishment of heretics under Theodosius I., who in 382 published an edict against the Manichæans and other sects. A law of Honorius in 398 threatened the professors of certain heresies, in particular the priests of the Montanists and Eunomians, with banishment and death if they persisted in bringing people together. The decrees for the extermination of heathenism were even more severe. Heathen sacrifices were forbidden by Constantius II. in 353, under pain of death. Theodosius I. in 392 proclaimed every form of idolatry a crime, and every attempt to learn the secrets of the future by animal sacrifices high treason. Theodosius II. remitted capital punishment in 423, but again enforced the law against heathen sacrifices in 426. Most of the earlier fathers were opposed to the punishment of heretics by the secular arm, and particularly to the infliction of death. Chrysostom and Augustine approved of their being confined or exiled, but only Jérôme and Leo the Great were in favor of the death penalty. The first instance in which the blood of a heretic was shed by the solemn forms of law occurred in 385, when Priscillian, the leader of a Gnostic sect in Spain, was put to death by the sword, at the instigation of Bishop Idacius. The church was struck with horror at the act; Idacius was excommunicated and died in exile. Justinian, in his code, provided certain penalties for dissenters from the orthodox creed as expounded by the "four holy synods" of Nice, Constantinople, Ephesus, and Chalcedon; and from this code the future legislation against heretics was derived. For several centuries all cases of heresy came before the ordinary courts; but in the course of time the examination of the charge of heresy devolved upon bishops, who handed over those who remained obdurate to the secular courts for punishment. Sometimes, however, ecclesiastical councils specified the punishment to be inflicted on certain classes of heretics. The organization and development of the synodal courts in the 8th

and 9th centuries systematized also the proceedings against heretics; but no special machinery for the purpose was devised until the spread in the 11th and 12th centuries of the Euchites, Bogomiles, Paulicians, Waldenses, and the various sects comprised under the common name of Albigenses. This excited the alarm of the civil as well as the ecclesiastical authorities, heresy being regarded at the time as a crime against the state no less than against the church. At the beginning of the 13th century Innocent III. sent several Cistercian monks as his legates to the south of France, in order to force the great feudatories of Provence and Narbonne into a war against the Albigenses, and to assist the bishops in searching out the heretics and in giving them over to punishment. The fourth council of Lateran in 1215 enjoined upon the synodal courts the searching out of heresy and its suppression as a duty, and may therefore be regarded as having established the legal foundation of inquisitorial courts. The bishops were called upon either to visit personally or to send delegates into every parish suspected of heresy, and to cause several, or if necessary all, of the inhabitants to swear that they would inform against heretics as well as those attending secret meetings; all who refused to take this oath should be suspected of heresy themselves. These arrangements were confirmed and enlarged by the synod of Toulouse (1229), which issued on this point 45 propositions, among which were the following: "Any prince, lord, bishop, or judge, who shall spare a heretic, shall forfeit his lands, property, or office; and every house in which a heretic is found shall be destroyed. Heretics or persons suspected of heresy shall not be allowed the assistance of a physician, or of any of their associates in crime, even though they may be suffering under a mortal disease. Sincere penitents shall be removed from the neighborhood in which they reside, if it is suspected of heresy; they shall wear a peculiar dress, and forfeit all public privileges until they receive a papal dispensation. Penitents who have recanted through fear shall be placed in confinement." The synod also enjoined upon the bishops to bind in every parish a priest and two, three, or more laymen by oath to search out heretics. But as many bishops were accused of being either remiss or partial, Gregory IX. transferred the inquisition to the Dominicans, first in 1232 in Austria and Aragon, and next in 1233 in Lombardy and southern France. The persons thus empowered and sent by the pope to different countries were denominated collectively "inquisitorial missions." To aid the inquisitors in the exercise of their office, a guild was founded after 1229, called the *militia Jesu Christi contra hæreticos*. The church, however, contented itself with the examination of the heretics, and called on the secular arm to carry the sentences into execution. Louis IX. of France from attachment to the church, and Raymond VII. of Toulouse and Frederick II.

of Germany in order to escape the suspicion of heresy, complied with this request, and made the execution of the sentences passed by the inquisitors obligatory. The procedure of the inquisitors differed in many particulars from that of the civil courts. In accordance with a decree of the councils of Béziers and Narbonne, confirmed by Innocent IV. in 1254, the informers were never named to the accused; suspicion of heresy was considered a sufficient cause of arrest; accomplices and criminals were admitted as witnesses. If the accused denied the charges, he might be put to the torture to obtain his confession. The regulations of the earlier inquisitions are found in the *Directorium Inquisitorum* of Nicholas Eymeric, who for 42 years held the office of chief inquisitor in Aragon, and died in 1399. It was first published at Barcelona in 1503; again at Rome, with a commentary by Pegna, in 1578; and has often been reprinted. The power of the inquisition was greatly increased by the income which it derived from the property of the condemned. Innocent IV. in 1252 assigned to it one third of such property, and ordered one third to be reserved for future uses; in the 15th century it was common for the inquisitors to claim the entire property. Until 1248 the inquisitorial courts were only transitory tribunals; but from that date they became permanent, and the institution was successively introduced in this form into Italy, Spain, Germany, and the southern provinces of France. The people in the south of France rose repeatedly in rebellion, and took bloody vengeance on some of the inquisitors, as at Toulouse in 1245. The parliaments declared themselves against its proceedings as irregular and unprecedented, and several kings, as Philip IV. and Louis XI., limited its jurisdiction. Its influence was also weakened by the schism of the 14th and the reformatory councils of the 15th century. After the reformation of the 16th century, Henry II., urged by Pope Paul IV., made an attempt to reestablish it, and even extorted the consent of the parliament to an edict of this kind; but it never regained strength, was wholly abolished by Henry IV., and has not been reintroduced.—In Spain the inquisition was introduced soon after its establishment in France. The Aragonese branch can be traced by authentic records as far back as the year 1232, and in the course of that century courts were established in the dioceses of Tarragona, Barcelona, Urgel, Lérida, and Gerona. At first it passed no sentence more severe than confiscation of property, and even this was restored if the accused abjured his opinions within a term called the "period of grace." Toward the close of the 15th century a new impulse was given to it by Cardinal Pedro Gonzalez de Mendoza, archbishop of Seville, and in time it assumed gigantic dimensions, becoming more absolute and independent than in any other state of Europe. The probability of a union between the Jews and Moors

against the Christians at that time excited in Spain considerable alarm. The Jews formed a large proportion of the population, and held enormous wealth. Severe restrictive measures were passed against them by the civil authorities from time to time, and finally about 1477 certain of the clergy proposed to Ferdinand to establish the inquisition in Castile, with the primary object of searching out those who having been converted to Christianity had relapsed into Judaism, or who feigned conversion while secretly attached to the faith of their fathers. The king readily assented, and, the consent of Isabella having been reluctantly given, a papal bull was procured in 1478 authorizing the establishment of the tribunal. From this date forward Catholic writers regard the Spanish inquisition as a state tribunal, a character which is recognized by Ranke, Guizot, Leo, and even Llorente. In September, 1480, a royal edict appointed two Dominicans the first inquisitors, and the first court was established at Seville. They issued their first edict on Jan. 2, 1481, by which they ordered the arrest of several "new Christians," as converts were popularly called, who were suspected of heresy, and on Jan. 6 the first *auto da fé* was held, when six persons were burned alive. Executions soon became frequent. Several of those who had been condemned as contumacious appealed to Pope Sixtus IV., who in January, 1482, complained of the conduct of the two inquisitors, and recommended mildness and moderation. Soon after he appointed the archbishop of Seville apostolic judge of appeal for all Spain, with power to decide on all appeals from the judgments of the inquisition. In 1483 Torquemada became grand inquisitor general of all Spain, and at the same time Ferdinand appointed a royal council of the supreme inquisition (*consejo de la suprema inquisicion*), of which the grand inquisitor was president of right and for life, with a bishop and two doctors at law as counsellors. Torquemada in concert with the king framed the organic laws of the new tribunal, styled instructions, which consisted of 28 articles, and were promulgated at Seville in 1484. Additions were made to them in 1488 and 1498; and at last a new compilation of regulations, consisting of 81 articles, was made by the inquisitor general Valdez in 1561, which remained ever afterward the guide of Spanish inquisitors. All the penitents of the inquisition wore a peculiar habit, called *sambenito* (a corruption of *saco bendito*, "the blessed vest" of penitence), of which there were three different kinds for the three classes of condemned, and an equal number for those who were doomed to suffer death. The *auto da fé* (act of faith) was, properly speaking, the public and solemn reading of the records of the court of inquisition, and of the sentence by it passed on persons found guilty; but it is popularly understood of the public ceremonies accompanying their execution. The accused themselves, if living, were always pres-

ent on the occasion; if dead, their remains or effigies were substituted for them. The civil authorities and corporate bodies were also bound to be in attendance, as well as the criminal judge and his officers, whose duty it was to have the sentence carried out. When the execution was performed with unwonted solemnity, it was called *auto publico general*. There was also an *auto particular*, or private act, at which the inquisitors and criminal judge only were present; the *autillo*, held in the palace of the inquisition, which was attended only by the ministers of the court and the persons invited by them; and the *auto singular*, which took place in the church or in the public square, and against a single person. The punishment was inflicted for what the ecclesiastical judges pronounced heresy, or a relapse into the same, or apostasy from the Christian faith. The *auto publico general* occurred rarely, and was held on the Sundays between Pentecost and Advent. The prisoners were conducted in procession to the public square, where royalty itself and all the highest personages in church and state attended, as at a drama which aimed at recalling the terrors of the judgment day. Those condemned to death were dressed in a sack of sheepskin called *zamarra*, and a conical cap called *coroza*, both hideously painted. Of the others, the more guilty wore a *sambenito* or sack of yellow stuff with a cross in red. Prisoners of the least guilty class wore a coarse black coat and pantaloons, and walked with bare head and feet. After the solemn publication of the sentences, the penitents were borne back to their cells in the prisons of the inquisition; and those condemned to the fire were offered a last option between death and recantation of the heresies with which they were charged. If they recanted, they also were conducted to prison. If they remained obdurate, they were handed over to the secular judge, and led to the *quemadero* or place of burning, which was generally outside of the city.—By its compact organization the inquisition soon became very powerful. The inquisitor general was appointed by the king and approved by the pope; but he was in reality independent of both. He named the subaltern officers, and had an absolute control over all the lower courts. The expulsion of the Jews (1492) and the Moors (1500) from Spain, which many tried to evade by conversion to Christianity, and later the spreading of Protestantism, furnished the inquisition with abundant occupation. According to the estimate of Llorente, whose accuracy has been called in question by Catholic writers, the number of those burned alive under Torquemada (1483-'98) amounted to 8,800, those under Deza (1499-1506) to 1,664, and those under Cardinal Ximenes (1507-'17) to 2,536. The general result of his statements for the time from 1483 to 1808 is as follows: burned alive, 31,912; burned in effigy, 17,659; subjected to rigorous pains and penances, 291,456. From the be-

ginning of the 17th century, when it had completely exterminated Protestantism in Spain, the inquisition became more lenient, and directed its efforts mostly to the suppression of heretical books. In the 18th century the *autos da fé* became very rare. Charles III. and his minister, Count Aranda, greatly restricted its jurisdiction, and Joseph Bonaparte entirely abolished it in December, 1808. It was restored by Ferdinand VII. in 1814, but again abolished by the constitution of the cortes in 1820. After the second restoration an inquisitorial junta reappeared in 1825, and in 1826 a tribunal was reestablished at Valencia. In 1834 it was again abolished, and in 1835 its property was confiscated for the payment of the public debt. The most complete work on the inquisition in Spain is Llorente's "Critical History of the Spanish Inquisition," translated into French by A. Pellier (4 vols. fol., Paris, 1817). An abridged English translation was published in London in 1826, and reprinted in Philadelphia. The author declares that he was secretary of the inquisition of Madrid during the years 1789-'91; that from 1809 to 1811 all the archives of the inquisition were placed at his disposal; and that he burned, with the approbation of Joseph Bonaparte, all the criminal processes except those which from their importance and the rank of the accused belonged to history. The accuracy of some of his statements is greatly doubted by many. Ranke does not hesitate to impeach his honesty; Prescott even pronounces his "computations greatly exaggerated," and his "estimates most improbable." The best work on the Spanish inquisition written from a Catholic standpoint is K. J. Hefele's *Der Cardinal Ximenes*, &c. (Tübingen, 1844).—An attempt to establish the Spanish inquisition in Naples was made by the Spanish viceroy in 1546; but the Neapolitans prevented it by energetic resistance. The towns of Lombardy successfully remonstrated against a similar attempt of Philip II., but it was introduced into Sicily and the Spanish colonies in America. In the latter the tribunals of Mexico, Cartagena, and Lima rivalled in severity those of Spain. Charles V. sent it to the Netherlands, where it greatly increased the discontent of the people with the Spanish dominion; and the attempt of Philip II. to reestablish it was among the principal causes which led to the revolt of the seven northern provinces and the rise of the Dutch republic. The inquisition was not introduced into Portugal till 1557. Its organization was nearly the same as in Spain. The supreme court of inquisition, to which all other courts of the kingdom were subordinate, had its seat at Lisbon; the grand inquisitor was appointed by the king and confirmed by the pope. John IV., after delivering Portugal from the Spanish rule (1640), intended to suppress the inquisition, but succeeded only in mitigating it. Its power was broken by King Joseph (died 1777) and his minister Pombal. John VI. (died 1826) abolished it both in Por-

tugal and in its dependencies, Brazil and Goa.—In Italy the inquisition never became as powerful as in France and Spain. It was introduced in 1233 against the Waldenses, and the chronicles of many Lombard towns mention the burning of heretics; but their number seems to have been less considerable than in France and Spain. A celebrated inquisitor, Pietro di Verona, who exercised his office with great severity during 19 years, was slain in 1252. In the 16th century courts for the suppression of Protestant doctrines were established in Tuscany, Venice, Milan, Parma, and other states; but their sentences remained subject to the sanction of the temporal sovereign. A supreme tribunal of the inquisition for the whole church, called the "Congregation of the Holy Office," and consisting of six cardinals, was established by Paul III. at Rome in 1543; but beyond the limits of the Papal States the authority with which the pope invested it was never conceded to it by the temporal sovereigns. Sixtus V. in 1588 changed the name of the congregation to that of the "Holy Roman and universal Inquisition," and made it to consist of 12 cardinals, with several assessors, consultants, and qualifiers (who had to prepare the cases). The Roman inquisition was the mildest of all tribunals of this nature, no instance having occurred of the punishment of death being inflicted through its agency. Napoleon abolished the inquisition in all Italy in 1808. It was restored in the Papal States by Pius VII. in 1814, and in Tuscany and Sardinia in 1833. Since the occupation of Rome by the Italian government in 1870 the inquisition has been abolished in the kingdom of Italy. The body bearing the name of "Congregation of the Holy Office" is composed of 12 cardinals, presided over by the pope. They pronounce on all questions relating to faith and morals, but have at present none but spiritual jurisdiction.—Outside of the territory of the Romanic nations the inquisition never gained a firm footing. In Germany it was established as early as 1231; but the severity of the first inquisitor, Conrad of Marburg, aroused so general and violent an indignation, that he himself was slain in 1233, and Germany remained for a long time without inquisitorial courts. An attempt to revive it was made in the 14th century in consequence of the appearance of the Beghards. Charles IV. in 1369 supported the inquisitors by three edicts. Pope Gregory XI. in 1372 appointed for Germany five inquisitors, and Boniface IX. in 1399 increased their number for northern Germany alone to six. In 1484 it was greatly extended for the purpose of ridding Germany of sorcerers and witches, but the reformation destroyed its power even in those portions of Germany which remained Catholic. Though attempts were made to restore it in Austria and Bavaria (1599), it never regained any considerable power, and since its abolition by Maria Theresa no trace of it has existed in Germany. In England, Hungary, Sweden, Norway, and

Denmark it was never permanently established; and in Poland, where Pope John XXII. introduced it in 1327, it was of but short duration.—A general history of the inquisition, critical and impartial, is still wanting. A critical survey of a number of works treating on the subject appeared in the "British Critic" in 1827, and was reprinted in the Philadelphia "Museum of Foreign Literature and Science" in the same year. See Limborch's "History of the Inquisition," translated by Chandler (London, 1731); Joseph de Maistre, *Lettres sur l'inquisition espagnole* (Paris, 1822); and W. H. Rule, "History of the Inquisition" (2 vols., London, 1874).

INSANITY (Lat. *insanitas*, from *in*, privative, and *sanitas*, health or soundness), unsoundness of mind. The term is usually applied to acquired unsoundness in contradistinction to that which is congenital, but treatises on the subject include the latter under the heads imbecility and idiocy. The legal relations of insanity will be treated under the synonymous but mere technical legal term *LUNACY*. Locke says that "madmen do not appear to have lost the faculty of reasoning, but having joined together some ideas very wrongly, they mistake them for truths, and they err as men do that argue right from wrong principles." It will be seen however, from an examination of cases, that not only are madmen the subjects of delusions and hallucinations, but that their reasoning faculties are generally more or less deranged, and sometimes entirely perverted. The attempt to treat mental diseases from a purely psychological point of view has been the cause of much useless labor, and has resulted in many erroneous conclusions.—Insanity appears to have been of rarer occurrence in ancient than in later times, and it is also seldom met with among primitive people of the present day. The occupations of both men and women in antiquity were not of a character calculated to excite cerebral disease, even if the predisposing causes had been present. It is, however, a matter of doubt whether insanity can be induced without a pathological basis, the tendency being to the opinion that it cannot. The earliest references to mental disease in antiquity are the madness of Saul, the feigned madness of David, and that of Ulysses immediately before the Trojan war. Although several instances of real or feigned madness are mentioned by the ancients, their writings contain no account of any institutions devoted to the care of the insane, nor any laws for their protection. The opinions expressed by Plato in the "Timæus" and "Phædrus," in regard to the prophetic power of madness, which he looked upon as a sacred disease and full of blessings, are well known. Ancient Greek authors, especially Euripides, abound with allusions to the supposed power of Bacchus to produce madness. Lycurgus, king of the Edones in Thrace, refused divine worship to Bacchus, for which the god visited him with madness.

In this condition, and under the delusion that he was cutting down a vine, he killed, according to Apollodorus, his own son. The three daughters of Prætus became insane for neglecting the work of Bacchus, and ran about the fields believing themselves to be cows. It is worthy of remark that in the Mosaic law there is no provision for insane persons. In the 6th century B. C. history records a remarkable example of insanity produced by epilepsy in the person of Cambyses, king of Persia and conqueror of Egypt. It is said that from his birth he was subject to fits of epilepsy, called the "sacred disease." The earliest medical writings which treat of insanity are those of Hippocrates. It is a remarkable fact that this earliest of observers should have, like those who are the most advanced in knowledge at the present day, regarded insanity as having a pathological basis, and that through all the intervening centuries the same sound opinion should have scarcely ever been thought of. He says: "And by the same organ (the brain) we become mad and delirious, and fears and terrors assail us, and dreams and untimely wanderings, and ignorance of present circumstances. All these things we endure from the brain when it is not healthy." One of the most noted ancient writers on insanity was Asclepiades. He believed in stimulation, and applied it in the treatment of insanity. He therefore recommended wine and recreation, and that the patient should be placed in the light, and discouraged bleeding and the use of narcotic fomentations. Celsus exercised a powerful influence upon the treatment of the insane from his time even to the present century. He wrote the first independent treatise on the subject, entitled *De Tribus Insaniæ Generibus*, in which he gives a compend of all that had up to his time been found to be the most correct views. He has received much praise from many authors, but his treatment was harsh and such as would not be tolerated at the present day. Arætanus of Cappadocia, according to the notions of his age, attributed melancholia to black bile, but says that sometimes it arises from mental causes alone. He describes the passing of the disease into imbecility and bodily decline, and shows a good knowledge of the different forms of mania. He also carefully distinguishes between the delirium of fever and of intoxication or of poison and that of insanity. Cælius Aurelianus, who is supposed to have flourished about the time of Galen, advised in mania the shaving of the head and the application of cups, first over the chest, then between the shoulders, and next to the head. As reason returned, he recommended moderate exercise, riding, walking, and reading aloud. Theatrical entertainments were prescribed for melancholics, the scenes being of a lively or sad character, according to the state of mind of the patient. Acquaintances were to be employed to converse with the patients and amuse them, and during

the progress of recovery they were allowed to go and hear the disputations of the philosophers. The celebrated Galen, who flourished in the latter part of the 2d century, based his treatment on the humoral pathology which was in such high repute among the ancients. He recommends that should you be of opinion that the whole of the patient's body contains melancholy blood, you should bleed, especially from the median cephalic vein. Should the blood not appear of a melancholy quality, the vein is to be immediately closed. Thick and black wine is to be avoided, "as from it the melancholy humor is made." After Aurelianus and Galen no medical writer of any eminence appears until the dawn which followed the middle ages. The practice of mental medicine during this period was based upon mystical theories, and cannot be said to have had a system. "That man is sick in mind," says Paracelsus, "in whom the mortal and the immortal, the sane and the insane spirit, do not appear in due proportion and strength." "Mania is a change in the reason, but not in the senses." And he gives for causes over exercise of the reason, the elements, influences, constellations, conjunctions, microcosm, macrocosm, &c. As to remedies he says: "What avails in mania except opening a vein? Then the patient will recover. This is the arcanum; not camphor, not sage and marjoram, not clysters, not this, not that, but phlebotomy." The first institution for the insane was established in the East. It is said that one existed at Jerusalem in the year 491. In the 12th century the traveller Benjamin of Tudela says there was a large edifice at Bagdad, called "house of grace," in which the insane were received in summer and kept confined in chains until they recovered or died. It was visited by the magistrates every month, and those who had recovered were discharged. In the same century hospitals for the insane were founded in the Byzantine empire, and asylums for them are said to have been common among the Moors.—The amelioration of the condition of the insane is not difficult to trace, as it had its commencement in modern times. Bucknill and Tuke remark: "It must be a matter of surprise that the principles of treatment so well laid down by one or two of the ancient medical writers should have been so entirely forgotten or disregarded. It is indeed to be presumed that the directions of Celsus have exercised a most prejudicial influence, even till within a very recent period; and it is not difficult to recognize them in the writings of the classical Cullen, who did not omit to recommend the employment of 'stripes' in the treatment of the maniacal." The pursuit of mental philosophy by the metaphysicians of the 18th century was not accompanied or immediately followed by any corresponding advance in the study or treatment of mental diseases. This was brought about by the investigations of physicians and the ef-

forts of philanthropists. Systematic writers on the subject of insanity have usually dated the commencement of reform from the labors of Pinel, and to that great man too much credit cannot be well given. "The year 1792," say Bucknill and Tuke, "will ever be memorable in the history of the treatment of the insane. In that year the celebrated Pinel liberated 53 of the patients confined in the Bicêtre from the chains by which it was thought necessary to restrain their fury." Pinel's labors were attended by great results, but he was not the pioneer in modern reformatory treatment of the insane. The subject had received the attention of Benjamin Franklin and others in this country as early as 1750. At the organization of the Pennsylvania hospital at Philadelphia a department for the care of the insane was established, in which the system afterward advocated by Pinel was successfully practised. An act was passed founding "a hospital for the reception and relief of lunatics, and other distempered and sick poor." (See annual address before the medical society of the state of New York, 1868, by Dr. John P. Gray.) The reform in the treatment of the insane in England, particularly in regard to restraint and punishments and mode of confinement, forms an interesting chapter in the history of institutions for the insane. Bethlem hospital, or Bedlam, as it was commonly called, which on various occasions became notorious for the ill treatment of the insane, was founded and first provided for them with benevolent intentions. In 1547 Henry VIII. took possession of the monastery or hospital of St. Mary of Bethlem, and presented it to the city of London, with an order that it should be converted into a house for the reception of lunatics. This building, however, could accommodate only 50 or 60 patients, and therefore in 1675 a larger one was erected in Moorfields, capable of receiving 150 patients, and which remained as a hospital till 1814. In 1734 additions were made to Bethlem, and it still proving too small, St. Luke's hospital was established in 1751 by voluntary subscription. The York asylum was founded also by general subscription in 1777. The management of the asylums had previously begun to retrograde, but not many complaints were made until the year 1791, when some members of the society of Friends sent one of their family to the York asylum. The rules forbade any of her friends to see her; suspicion of something wrong was aroused, and a new establishment called "the Retreat" was founded by the society, chiefly through the influence of William Tuke, in the spring of 1792, the year in which Pinel caused the lunatics in the Bicêtre to be liberated from their chains. At the retreat no chains, leg locks, or handcuffs were employed from the opening of the establishment. A patient who had been chained naked for 20 years was admitted; no restraint except the occasional use of arm straps

was employed, and he was soon induced to wear clothes and adopt orderly habits; and there were many other cases of a like nature. Little was publicly known of the experiment till 1798, when De la Rive visited it, and was so delighted with what he saw that he published an account of it on his return to France. The publication of a "Description of the Retreat," by Samuel Tuke, in 1813, attracted still more attention to the institution. The physician of the York asylum took offence at some observations it contained, and a controversy arose which resulted in exposing a number of aggravated cases of bad management in the other asylums, and also in causing the house of commons in 1813 to appoint a committee to investigate the subject, who visited not only Bethlem and York asylums, but many private institutions, and brought a horrible condition of things to light. Among the minutes of evidence taken before the committee are the following. One witness, Mr. Edward Wakefield, said: "In the year 1808 I heard a physician state to the Rt. Hon. John Foster, that of the insane persons who were sent up to Dublin the treatment of them was so little understood that the accustomed mode was tying them with a cord to the back of a car and forcing them to walk the distance they might have to come; and this gentleman's expression was, 'I give you my honor that of the insane persons sent up to Dublin almost one in five loses an arm from the tightness of the ligature producing mortification, which renders amputation necessary.'" Dr. Richard Salisbury, a general practising physician, testified: "In one house the number of patients confined is 23, 14 men and 9 women; 7 of the men and 7 of the women supported at their own expense. One room was on the ground floor, 21 by 16 ft. and 7 ft. high, divided into 6 cells, 9 ft. long and 5 ft. wide, with a passage 3 ft. wide between; not the least air or light admitted except when the doors are open. The principal door immediately opposite a pig sty and dung heap about 7 ft. distant. Three only of the cells floored with wood, the other three were on the bare earth. A long box, 6 ft. by 2½ ft., was used for a bedstead, to which the patient was chained. Some had blankets, some only coarse straw. They were taken out to air once a week, during which time clean straw was supplied when necessary. The patients were so dirty in their persons that on opening the door of the first cell the smell was so offensive as nearly to prevent further inspection." The medical treatment in most of the establishments was of the lowest empirical kind. The physician of Bethlem said: "Twice a year, with few exceptions, the patients are bled, and after that they take vomits once a week for a number of weeks, and after that we purge them. That has been the practice for years, long before my time." But it must be remembered that although much of the treatment arose from cruelty and negligence, the system

was supposed by the more ignorant to be one of necessity. Lunatics were not looked upon then as unfortunate sufferers from disease, but rather as subjects of demoniacal possession, or as self-made victims of evil passions. The exposure of the abuses aroused the public mind, and medical men not only felt called but were forced to pay more attention to the study of humane methods of treating the insane, and to emulate the example of the Tukes at the retreat.—*Causes.* The causes of insanity may be divided into predisposing and exciting. The more general predisposing causes are sex, age, social position, education. The question as to the influence of sex has not been definitely settled. Alienists are agreed that the existing statistical tables do not settle the question, and that asylum reports are apt to mislead, as the minority of female patients in asylums may be owing to the greater unwillingness of friends to send them from home than males. The statistics of Esquirol embrace about 70,000 patients of all countries, and show a small majority of females, and he and also Haslam thought insanity more frequent among women than men. It has been said that women are more liable than men to inherit insanity, and Dr. Maudsley is inclined to this conclusion. In regard to the influence of age, cases of insanity are rare in childhood. The greatest number become insane between 25 and 50. It is difficult from statistics to determine the effect of social position. In England there are about 9,000 poor and 1,300 members of wealthy families in public and private asylums, and this is probably about the proportion of the poor to the rich; but it is probable that a state of poverty is more productive of mental disease than one of affluence. Insanity has been found more frequent among unmarried men and married women. Its greater frequency among married women is probably owing to care, anxiety, and over-exertion of body and mind, and difficulties in gestation, lactation, and menstruation. Of the more special predisposing causes, heredity plays a most important part. Jacobi in 220 cases of mania found hereditary predisposition in about one ninth. Hagen in 170 cases found it in about one third. Esquirol found it among the poor in more than one fourth; in the rich, about three fifths. Webster found at Bedlam, in 1,798 patients, hereditary predisposition in about one third, oftener in females. Skae of Edinburgh, in 248 admissions, found it in a little over one third. In a large number, from English and Irish asylums collected by Dr. Jarvis of Massachusetts, it was found among 44,417 men in the proportion of $\frac{1}{5}$, and 43,093 women of among $\frac{1}{3}$. At Bloomingdale asylum the proportion was found to be about one sixth. It was advanced by Esquirol, and confirmed by Baillarger in the examination of 453 cases, that insanity is more frequently transmitted from the mother than from the father. It was found that the transmission from the mother to the sons was only about equal to that

of the father; but the transmission to the daughters was twice as frequent. This would indicate that women inherit insanity oftener than men, a point previously alluded to. It is also found that children who inherit insanity sometimes manifest the disease before the parents do; but they are more likely to inherit it if born after its appearance in the parents. There is also a tendency in hereditary insanity to show itself in much the same way in the different individuals of the family; thus it has been observed that a whole family of brothers and sisters have become insane at about the same age, and committed suicide. The disposition may be removed by marriage with healthy stock, or may be increased by intermarriage.—The exciting causes of insanity may be divided into moral or psychical and physical. The principal psychical causes are grief, fright, anxiety, care, or an excited state of any passion, particularly if recurring often or prolonged; the emotions aroused by disappointment, by unfortunate love, by jealousy, by reflecting on misfortunes that have ruined the prospects of life; excessive or prolonged employment of the intellectual faculties, particularly when connected with the emotions, as the composition of poetry or romance, or the prolonged excitement attending the management of difficult legal cases. Anything which will produce a hyperæmia of a portion or of the whole of the brain, by which the nutrition and consequently the normal function is interfered with, may become an exciting cause. From the number of cases of insanity in men of business, who have broken down in the struggle to amass fortunes, it is fair to assume that the prominence given by Maudsley to the eager desire to get rich as a cause of insanity is amply justified. He says: "The occupation which a man is entirely engaged in does not fail to modify his character, and the reaction upon the individual's nature of a life which is being spent with the sole aim of becoming rich is most baneful. If one conviction has been fixed in my mind more distinctly than another by observation of instances, it is that it is extremely unlikely that such a man will beget healthy children; that, in fact, it is extremely likely that the deterioration of nature which he has acquired will be transmitted as an evil heritage to his children. In several instances in which the father has toiled upward from poverty to vast wealth, with the aim and hope of founding a family, I have witnessed the result in a degeneracy, mental and physical, of his offspring, which has sometimes gone as far as extinction of the family in the third or fourth generation." The principal physical causes are drunkenness and the use of narcotic or poisonous drugs; want of food; want of sleep and over-exertion; other nervous diseases, such as epilepsy, chorea, and hysteria, particularly the first; severe injuries to the head, particularly from blows, causing fracture of the skull or concussion of the brain; sun-

stroke, and tumors in the brain. Acute febrile diseases, as typhoid, typhus, and malarial fevers, are also causes of insanity; and it may occur during the course of pneumonia, generally in the form of acute mania. The poison of Asiatic cholera may so interfere with the nutrition of the brain as to produce not only transient delirium, but mania, which may continue for several days or weeks. Acute rheumatism is sometimes a cause of insanity; and it is an interesting fact that the mental symptoms follow the apparent disappearance of the rheumatic symptoms, and pass away upon the reappearance of the disease. Chronic constitutional diseases are frequent causes, and among the most formidable probably of these is constitutional syphilis. Its effects are produced in a variety of ways. The skull may be the seat of exostosis or of caries; the membranes may be affected and cause mal-nutrition of the cerebral substance; or tumors of the brain may arise directly from the effects of the syphilitic poison; or the nutrition of the whole body may be so interfered with that all the plastic material furnished by the food is vitiated and incapable of forming sound nervous tissue. The syphilitic affections of the nervous system have recently been the subject of careful examination by Drs. Wilks and Moxon. According to Dr. Wilks, there is in syphilis a disposition to a low form of lymph in nearly every tissue of the body, which does not readily form tissue, never that which is perfectly normal. According to Dr. Moxon, syphilis attacks the surface of the brain and its membranes in limited spots, spreading slowly. The lymph which exudes from the membranes destroys the gray matter of the convolutions, and syphilitic deposits may form fleshy tumors which contain a certain gummy characteristic substance; or the brain and spinal cord may be invaded by gummatous tumors springing from the dura mater or the bones. Paralysis of various degrees of intensity and extent, and also mental diseases, are the results. (See lectures of Dr. Broadbent, "London Lancet," 1874; also an illustrative case, with plates of pathological changes, "American Journal of Insanity," July, 1874.) Tuberculosis, particularly by inducing a state of exhaustion or degenerated tissue development, is sometimes an exciting cause of mental disease; and, as will be noticed further on, there are apparently intimate relations between tuberculosis and insanity and certain other forms of nervous disease. Diseases of the heart have been assigned as causes of insanity, and as far as they operate in exhausting the strength of the patient, they may be considered as such; but more often the heart disease is, along with the mental affection itself, the effect of other changes, such as disease of the arteries or capillaries, or of the vaso-motor system of nerves. Disease of the genital organs sometimes exerts an important influence in producing insanity. During the period of sexual de-

velopment, particularly when any morbid condition is present, resulting from secret vice or from any cause, insanity in some form, mania, melancholia, or dementia, is liable to occur. Disorders of menstruation at any period of life may bring on attacks of mental disease; as also may diseases of the uterus or ovaries, such as tumors, cysts, or displacements. Pregnancy, the puerperal state, and lactation are not infrequent causes of mania and melancholia. A state of melancholy during pregnancy is often the precursor of an attack of puerperal mania. Insanity from lactation is generally in consequence of the exhaustive effect of the function superinduced upon a hereditary predisposition. Sexual excess and unnatural vice, from inducing a perverted condition of the mind and nervous system, as well as from their weakening effects, are not uncommon exciting causes of insanity. But among all the causes of mental disease, it is acknowledged by most authorities that the excessive use of intoxicating drinks is the greatest. Of 1,428 cases admitted into Bethlem hospital, 12 per cent. were found to be caused by intemperance. The report of the commissioners in lunacy in England in 1844 gives, out of 9,868 cases, 1,792, or more than 18 per cent., as the proportion attributable to the effects of alcoholic liquors. Of 748 cases, Halloran found drunkenness a cause in more than one fifth. Prichard and Esquirol attribute half of the cases of insanity in England to intemperance. Dr. Rush gave it as the cause in one third of the cases in America, and more recent statistics of some asylums show a larger proportion. Blandford and other modern writers ascribe to it a potent influence. Dr. Dickson, late superintendent of St. Luke's hospital, London, takes a somewhat different though not opposite view. He says: "Although it is true that drunkenness is very frequently the exciting cause of an attack of insanity, yet the incentive to drunkenness is the result rather than the cause of brain deterioration in the first instance; a potentiality of insanity is often discovered on examining the history of the persons who complain of a constant sense of depression, and who seek to relieve that depression with stimulants." The continued use of intoxicating drinks and narcotic poisons, in the opinion of Dr. Carpenter ("Mental Physiology," 1874), destroys or weakens the will so that it loses its control over the emotions. The experiences given by De Quincey as to the weakening of the will in his own case, so that he became unable to perform what he had planned, not from want of brain power, but of volition, is instanced by Dr. Carpenter as an example; and he also points to the excessive use of tobacco in creating a mental state which manifests itself in deferring the performance of pressing duties. The effect of alcohol he regards as more potent in weakening the will and arousing the more violent passions than that of any other agent; and it is not improbable that the excessive and habit-

ual use of alcoholic beverages, which are produced in such great quantities by civilized countries, has had much to do in inducing a hereditary tendency to insanity, and causing the spread of mental maladies to a greater extent among civilized than among other nations. The researches of Morel on the cause of the formation of degenerate varieties of the human race are interesting as explaining the continuance of morbid action through succeeding generations, and the final extinction of families. The evil influences which produce disease, such as the poisonous air of a malarious district, or a badly drained and cleaned city, overcrowding and privation in large towns, persistent intemperance and sexual excess, and intermarriage in families, unless counteracted, appear to tend to increase through generations, until continuance of the species is impossible. He regards insanity in any form, whether mania, melancholia, or dementia, as a stage in the descent toward sterile idiocy, as sometimes shown by the consequences of frequent intermarriages in foolish families. He relates the history of one family in which the progress of degeneration may be briefly stated as follows: first generation—immorality, alcoholic excess, brutal degradation; second generation—hereditary drunkenness, maniacal attacks, general paralysis; third generation—sobriety, hypochondriasis, lypemania, systematic mania, homicidal tendencies; fourth generation—feeble intelligence, stupidity, first attack of mania at 16, transition to complete idiocy, and probable extinction of the family.—*General Symptoms of Insanity*. The earliest symptoms of coming insanity are depressed manner, unusual excitement, anger, and rashness; and even these may be preceded by an altered manner, if careful notice has been taken. An abnormal condition of brain exists, including a want of nervous energy which creates a consciousness that there is something wrong; a want of coordination of the faculties produces false reasonings and conclusions as to the nature of the difficulty, and so as the disease progresses delusions and hallucinations make their appearance. An important symptom in all forms of insanity is impairment of the faculty of attention, as might be expected from the loss of will which directs the attention. The inconsistency of the beliefs of the insane is one of the earliest noticeable symptoms, and they are conveniently classified as “delusions” and “hallucinations.” It is important that a clear conception of the meaning of these terms should be had. A delusion is a false belief in regard to some fact which generally concerns the patient, and which is so strongly rooted that all attempts to reason him out of it are futile. Thus, he may believe that a certain occurrence took place at a certain time, or that he is a certain person, as a saint, or a prince, or the Saviour, or that his head is made of metal. The delusions of the insane may be of a gloomy or of an exalted nature. A man who believes

poverty to be the greatest evil may, in consequence of false reasoning as to the state of his affairs, imagine himself to be ruined, and that his family will be turned out of doors. When the patient has exalted delusions he is apt to imagine himself immensely wealthy, or that the asylum in which he is confined is a palace and himself a monarch. A hallucination is a false perception of one of the senses; the patient may fancy that he sees a spirit, or a person who does not exist; such hallucinations are common in the temporary insanity of delirium tremens, when the patient may imagine that he sees serpents, or frogs, or insects, or that people, generally those whom he dislikes, come into the room. Hallucinations affect the different senses; thus the insane have hallucinations of sight, of hearing, of taste, of smell, and of touch. Hallucinations of sight are more liable to occur when the brain is in the greatest state of exhaustion, and to accompany the acute stages. They may be simply flashes of light or colors, or they may be objects like those in the state of exhaustion called delirium tremens. The hallucinations are oftentimes visions of the supernatural. Epilepsy in the insane is constantly accompanied by hallucinations of sight. Hallucinations of hearing occur in acute, but are more frequent in chronic cases, and are unfavorable symptoms; and those who are subject to them are often the most dangerous patients. They are liable to hear voices commanding them to perform certain acts, which they are blindly impelled to attempt, however absurd or destructive. Hallucinations of smell are generally not persistent, and belong to the acute stages; and those who have them are apt to imagine that their own persons have an intolerable stench. Hallucinations of taste are rather uncommon, and are generally associated with disordered digestion. Those of feeling are not uncommon, and patients often declare that they feel themselves touched, or that they feel snakes or other animals in their bodies. The acts of the insane are prominent symptoms. There is a proneness among them to strip off their clothes, arising from various causes. They often experience a feeling of uneasiness, often of heat from the pressure of their clothes, or they imagine that they are foul or poisoned. Sometimes in mania there is a desire to destroy them, and in other cases to expose the person. The desire to dress in a fantastic garb is common among the insane. In states of exaltation, whether of mania or of melancholia, the patient will often desire to assume a dress of authority, and the dejected melancholic will assume the most careless appearance. In some forms of insanity there is often a disposition to commit acts of violence and destruction. Sometimes these acts will be directed against inanimate objects, sometimes against other persons, and sometimes against the patient's own person. In the two latter instances it has received the

names of homicidal and suicidal insanity. Some authorities contend that such a classification should not be made; but there are too many cases furnished by insane asylums, and which have occurred under the notice of intelligent physicians, where lunatics have shown morbid impulses to commit wrong acts which they had not sufficient will to resist, to leave much room for doubt that such states of the mind do occur. Patients have under some circumstances committed deeds of violence under the influence of impulses, and have at other times, in anticipation of the coming on of those impulses, asked to be restrained, saying that they feared they would not be able to resist them. Considering the morbid perversion of the nervous system and the unhappy condition of the mind in some instances, it is not strange that the combined effects of these and of insane delusions and hallucinations should result in such acts, nor that the disposition to commit violence should under the circumstances take these forms.—*Classification.* There have been many classifications of insanity, but they have not thrown much light upon its nature, and in many cases have rather been hindrances to the discovery of the most important conditions (pathological) of the patient. The older writers divided insanity principally into mania and melancholia. Thomas Arnold in 1806 made a general division into ideal and notional insanity. The ideal he subdivided into: 1, phrenetic, or raving; 2, incoherent; 3, maniacal; 4, sensitive. Notional insanity he divided into: 5, delusive; 6, whimsical; 7, fanciful; 8, impulsive; 9, scheming; 10, vain or self-important; 11, hypochondriacal; 12, pathetic; 13, appetitive. The pathetic he subdivided into 16 varieties: 1, amorous; 2, jealous; 3, avaricious; 4, misanthropic; 5, arrogant; 6, irascible; 7, abhorrent; 8, suspicious; 9, bashful; 10, timid; 11, sorrowful; 12, distrustful; 13, nostalgic; 14, superstitious; 15, enthusiastic; 16, desponding. Pinel made four divisions, viz.: mania, melancholia, dementia, and idiocy. Esquirol added to these another, monomania. Dr. Prichard, whose work, published in 1835, was for a long time high authority, made two general divisions, moral and intellectual insanity, subdividing the latter into three, monomania, mania, and dementia. The existence of such a disease as moral insanity is not recognized by a majority of modern alienists, and it is contended that the moral sentiments are often wanting in persons who are considered sane, as well as in the subjects of mental disease. Dr. Daniel Tuke divides insanity according as it affects—1, the intellect; 2, the moral sentiments; 3, the propensities. Maudsley classifies insanity into two great divisions, which are subdivided into varieties as follows: I. Affective or pathetic insanity, including: 1, maniacal perversion of the affective life, *mania sine delirio*; 2, melancholic depression without delusion, simple melancholia; 3, moral alienation

proper. Approaching this, but not reaching the degree of positive insanity, is the "insane temperament." II. Ideational insanity, subdivided into: 1, general (*a*, mania, acute and chronic; *b*, melancholia, acute and chronic); 2, partial (*a*, monomania; *b*, melancholia); 3, dementia, primary and secondary; 4, general paralysis; 5, idiocy, including imbecility. In the first division the intellect may be comparatively unaffected, but there is insanity of feeling and action. In the second there is insanity of thought, or delusion. The "insane temperament" is a kind of potential insanity introduced by Maudsley to characterize a condition of mind in which great eccentricity of thought, feeling, and action, proceeding from a morbid nervous organization, does not make the person actually mad, but queer and morbidly eccentric. Individuals having this temperament have certain marks of genius, though never of the highest order. Griesenger, one of the highest modern authorities, says: "A classification of mental diseases according to their nature, that is, according to the anatomical changes of the brain which lie at the foundation, is at the present time impossible." He therefore classifies insanity according to the nature of the psychical symptoms, and says "that while it is the aim of clinical instruction to render conspicuous and to analyze the multiplicity of mental disorders in the concrete, nosology must content itself with establishing fewer principal groups, fewer abnormal states to which all the varieties of individual cases may be referred." He divides mental diseases into two grand groups. In one there is a morbid condition of the emotions, affecting, according to its nature, the whole mental life of the patient. In the other group insanity consists in disorders of the intellect and will, which exhibit, "without profound emotional excitement, an independent, tranquil, and false mode of thought and of will, usually with the predominant character of mental weakness." In most cases the conditions found in the first group precede those in the second, the latter generally being consequences and terminations of the former. The different forms of insanity may be conveniently considered under the following divisions: 1, melancholia; 2, mania; 3, general paralysis of the insane; 4, dementia; 5, imbecility; 6, idiocy.—*Melancholia.* This may be acute or chronic. The great majority of cases of insanity commence with a state of emotional perversion of a depressing and sorrowful character, which has been called the *stadium melancholicum*, or initiatory period of mental disease, or the period of incubation. The first stages of melancholia are generally preceded by a condition called hypochondriasis, which may be considered as the mildest form of insanity. There is a feeling of bodily illness at this time more than at any other, or in any other form of insanity. It is often vague, and depends upon irritation of the nervous centres arising from disorders, some-

times obscure, of the viscera. The patient becomes peevish and suspicious, is easily fatigued, a mental apathy takes possession of him, and he becomes weary of life; or he passes into a state of extreme anxiety. The mention of a disease will often cause him to fancy that he is afflicted with it, and he is constantly feeling his pulse and examining his tongue and excretions. He often changes his physician, and also his opinion of the nature of his ailment. His feelings are not all imaginary; there is frequently indigestion, sometimes of an aggravated character, accompanied with great evolution of gas, which by its distention of the intestinal canal occasions uneasiness. The tongue is foul, the appetite irregular, the bowels constipated, and the skin in an unhealthy condition. Moral treatment is often beneficial, but should always be accompanied by therapeutical measures calculated to remove pathological conditions. This state is very often accompanied by an inherited tendency to mental disease, and when not relieved passes into that condition more definitely styled melancholia. His delusions take a more decided character, and he fancies himself a criminal. He is now evidently to all observers an insane man, and becomes the subject, not only of delusions, but of hallucinations; he imagines that he is beggared, and that his family are to be thrown helpless on the world; that he is destroyed by odious diseases; that he has leprosy, and that a loathsome smell emanates from his body. His countenance expresses intense woe, and he stands for hours in one place and in one posture, either in solitude or in the street; or he may be impelled to constantly wander about. He sleeps badly, and generally eats but little; the bowels are obstinately constipated, the breath offensive, and the pulse slow and weak. The age at which persons are liable to melancholia is often the prime of life, or when the vigor is beginning to fail, at 40, 50, or 60 years. Of 338 cases of melancholia admitted into St. Luke's hospital, London, only 9 were under 20 years of age. Women who have been weakened by parturition are sometimes the subjects, when it generally assumes an acute form, with sleeplessness and obstinate refusal of food. In this state there is almost always a disposition to commit suicide, which may manifest itself suddenly; sometimes it appears earlier in the disease, even before the other symptoms have been observed. The treatment of a case of chronic or sub-acute melancholia will vary with its history and symptoms. An asylum is not indispensable if the patient's means are sufficient to provide him with proper care. He may be benefited by travel and change of scene; but, when his condition will not admit of this, a proper place, either a private house or an asylum, should be selected, and an attempt made by therapeutical and hygienic measures to restore the cerebral defect by sleep and nourishment of the body. In many cases

recovery will be observed to rapidly follow medical treatment alone, some bad cases getting well in a couple of months. There are three conditions which require constant attention: want of sleep, rejection of food, and constipation. To remedy the first, chloral is much used by some; others prefer the effects of morphine or Dover's powder, believing that chloral is better suited to the more violent condition of mania. Wine and brandy are also used to give temporary strength, and have been observed to be of practical benefit, inducing sleep in some forms of insanity. As to whether the dyspepsia and other visceral disorders are the cause of the melancholia, or whether they are in common with it, the result of a primary nervous disorder, is one of those disputed matters about which physicians will probably never be perfectly agreed. The practical aim is, however, to produce regularity of the evacuations by laxative medicines, and to sustain the strength with nourishing food and wine. The prognosis in cases of melancholia is generally good. Some have recovered after having been a long time in asylums, and subject to suicidal impulse and delusions and hallucinations. If the melancholy becomes paroxysmal, or runs into mania, the prognosis is not so favorable, as pathological cerebral changes of a permanent character are liable to occur. The symptoms are intensified; there is now no longer mere depression or silent stupor or anxiety, but the patient becomes frenzied. He will hardly sit or lie in one position for a moment, and has to be placed in restraint, either mechanical or manual. He is extremely suicidal, and will not only try to put an end to his life, but will attempt to injure his person by gouging out his eyes, or swallowing nails or pieces of glass or corrosive liquids. He is not liable, like a subject of general paralysis or an epileptic maniac, to make homicidal attacks; but he will resist with violence the assistance of his attendants. He will not take food, will not be washed or remain in bed, and will strip himself of clothing. There is an increased weakening of the will, indicating great deficiency in cerebral nutrition. There is a great tendency to sink rapidly from exhaustion, and therefore the patient has generally to be forcibly fed, or, as is said, to be fed "mechanically." This is accomplished by forcibly opening the jaws and putting nourishing food into the pharynx with a spoon, or by introducing it with the œsophageal tube, which is generally preferred. Gentleness, however, will sometimes succeed in prevailing on the patient to swallow his food voluntarily, and must of course be tried until found of no avail. One great danger is death from starvation, and therefore food must be given, and in considerable quantities. Chloral is considered appropriate, and may be given alone, or in combination with conium, hyoscyamus, &c. If the patient refuses, it may be given by the rectum. Morphine is also of service,

particularly in the form of subcutaneous injections. Constipation is to be relieved by laxatives and clysters. Other medicines, as bromide of potassium and digitalis, according to Blandford, are not worth the trouble of administering. Warm baths will be of great benefit, and the room should be kept warmer than usual. The patient wastes rapidly, and it is often impossible to give him enough food. Another form of melancholia of a chronic character often follows an attack of mania. It is attended with less mental excitement, resembling more a state of dementia, but recovery from it sometimes takes place.—*Mania*. This is usually classified, in a general way, as acute and chronic, and Blandford adds a variety which he calls acute delirious mania. *Mania*, particularly where there is hereditary taint, may be brought on by grief, misfortune, or disappointment; but peculiar forms of it accompany epilepsy and general paralysis of the insane. Acute mania may come on suddenly, or it may be preceded by melancholy lasting for some time. The symptoms of acute mania are by no means obscure; there is almost always manifested extreme mischievousness, filthiness in person, and obscenity in language. One distinction between mania and melancholia is in the manner the mental state affects the acts. There may be delusions in mania, but they are of a more confused kind and the acts are more purposeless, while in melancholia there is the evidence of some plan. The conversation is more incoherent. Maniacs will heap abuse on all around them, and are inclined to use violence. They commit self-abuse, and may become shameless in the exposure of the person. The bodily health often does not suffer greatly, and they seldom die unless their health is broken at the commencement of the attack, in which case they may wear themselves out. They eat heartily, but generally grow thin, although not very rapidly. There is want of sleep. Sometimes they will pass a good night, getting several hours of sleep, and then may go several days with only two or three hours' sleep, shouting, laughing, and singing. The tongue is often clean, and the bowels are not generally constipated; hence maniacal cases do not yield to medical treatment as readily as some cases of melancholia. Chloral may be of benefit to procure sleep. The doses should be large, from 40 to 60 grains. Opiates are given by some and condemned by others. The prognosis, when acute mania is not complicated with other disease, is on the whole favorable. Much, however, will depend on the time which has elapsed since the commencement of the attack. If this has been long, recovery will be doubtful because of the changes which have taken place in the brain, a continued state of hyperæmia producing chronic thickening of the cerebral membranes and changes in the brain substance. The patient may recover, or die with a hyperæmic state of the brain, or gradu-

ally sink into a state of hopeless chronic mania or dementia, or become melancholic. From this he may recover, and again become maniacal. Acute delirious mania, as described by Dr. Blandford, differs from the preceding in being accompanied with more delirium and with more bodily disorder. The tongue is often coated, sometimes brown and dry, and as the patient becomes exhausted a typhoid condition ensues. The urine is scanty and high-colored, and the bowels rarely act without laxatives. The treatment consists in regulating the bodily functions, giving food freely, combined with plenty of drink, and also wine, and in the judicious use of hydrate of chloral. Opium should not be given, as it obstructs the secretions and is liable to increase the delirium. Rest is of the highest importance, and baths of warm water, in which mustard may be stirred, are of great benefit, the head to be kept cool during the operation. Purgatives at the outset of the attack may be of use, as aiding to arrest it. The termination is almost always recovery or death, melancholia or dementia rarely following. Where an acute case of mania is neglected or badly treated, or is of a violent and persistent kind, it may pass into a chronic state in which there is either constant excitement of a less violent kind, or a fixed delusion. The patient gradually becomes feebler in intellect, although his bodily health may improve, and with variable degrees of rapidity sinks into a state of dementia.—*General Paralysis of the Insane*. The peculiar form of disease accompanied by insanity to which this name has been given is of the most formidable character, no instance of recovery in a well marked case having been recorded. The French physicians are entitled to the credit of having first recognized and described it. Esquirol was aware of the complications of insanity with paralysis, but did not recognize the whole as a distinct disease. Bayle in 1822 attributed the cause to chronic inflammation of the arachnoid, and named the disease *arachnitis chronique*. M. Calmeil in 1826 gave a complete account of it, and for that reason he is often called its discoverer. It has received several names, as *folie paralytique*, *paralysie générale progressive*, and *Geisterkrankheit mit Paralyse*. In England and America it has usually been called general paralysis of the insane, or paralytic insanity, and lately it is often called simply "paresis." It is generally regarded as presenting three stages: 1, the period of incubation; 2, the acute maniacal period; 3, the period of chronic mania, lapsing into dementia, with utter prostration of both mind and body. At the commencement of the disease an alteration in the manner of the patient may be observed, similar to that which is noticed in other forms of insanity, although there are commonly other symptoms which are of importance in forming a diagnosis, such as excessive extravagance in the spending of money. A general paralytic is liable to com-

mit outrageous and immodest acts, such as exposure of person and foolish assaults upon women; he is easily aroused into a passion, which often rises to uncontrollable fury; he neglects his business, fails to keep appointments, and exhibits a general weakening of the mind similar to that in the commencement of senile dementia. This, occurring in a vigorous man, cannot but be regarded as a remarkable symptom, and of alarming import. These symptoms increase rapidly, so that the disease will have greatly advanced in a few weeks. He sleeps badly, eats and drinks irregularly and often voraciously, spilling his food on his dress, of which he takes but little care. He is for a time sullen and morose, but as the disease advances grows more and more excitable; and it soon becomes evident that he needs restraint. A maniacal condition ensues, in which he assumes airs of great importance, imagines himself possessed of unbounded riches, and the owner of studs of the fleetest horses. An ordinary maniac may imagine himself a duke and the possessor of vast wealth, but he will show some consistency in adhering to the same delusion; while the general paralytic will style himself a duke, a prince, and a king almost in the same sentence, and will announce his intention of doing a hundred impossible things on the next day. He has extravagant notions of his intellectual, and particularly, of his physical strength, and when in the last stages of bodily weakness will maintain that he can perform the most wonderful feats. He nearly always says that he feels well, even when not able to feed himself. In consequence of these peculiar symptoms, the French have called the disease *manie des grandeurs*. His speech generally shows the first effects of paralysis, although it sometimes commences in the lower extremities. The articulation becomes obstructed, somewhat like that of a drunken man. It is not a true stammer, but shows a want of power over the vocal organs. There is often a peculiar tremulousness of the lips, such as is seen in grief. The defect in speech varies from time to time, sometimes not being noticeable except to the practised physician, and at others rendering the patient unintelligible. The subjects of the disease are almost always men in the prime of life. It does not attack boys or old men, and rarely women. The violence of the mania attending general paralysis is of the most dangerous character; its subjects become possessed with a blind fury, and know not what they are about. In this stage they are not paralyzed sufficiently in their limbs to prevent them from doing serious harm; therefore the restraints of an asylum are almost absolutely necessary. Other symptoms appear in time. Fits resembling apoplexy or epilepsy occur from time to time, dividing the disease into stages. They are called "congestive," or "paralytic," or "epileptiform" attacks, and resemble sometimes the *petit mal* of epilepsy, at others the

grand mal. Again, they may not be attended by any convulsion, but by sudden collapse and paralysis, which slowly passes away. The epileptiform attacks have not the definiteness of epileptic fits, but may last an hour or two, or pass off so rapidly that the patient may continue standing. It is important to distinguish these fits from those of true epilepsy, as the latter are more benefited by treatment, even when accompanied by insanity. In fits of general paralysis patients seldom bite the tongue, while in epilepsy they almost always do. The pupils of the eyes will generally be found irregular, and when this symptom is present it is important. In 108 cases of general paralysis examined by Dr. Nasse of Siegburg, the irregularity was present in all but three. Dr. Austin found only two exceptions in 100 cases. Irregularity of the pupils may, however, exist in other forms of insanity, and also in the sane in other affections of the brain, but it is much more rare. When accompanied with the other symptoms of general paralysis, it may be considered pathognomonic. The course of general paralysis has an average duration of about two years; some few cases last only a few weeks, and some may run on for five or six years. The maniacal or second period may last from a week to two months, and generally yields to treatment, the patient getting better, so that he is able to go about and appear like a sane man for a while; or he passes into a state of dementia, and so on downward to extinction of mind and body. Sometimes after apparent recovery the subjects of this disease may attempt to reëngage in business, but such attempts have always been found to fail. The last stage, that of dementia, is sad indeed, and it is fortunate that the disease is rapid in its progress. The patient can scarcely walk or feed himself, and there is constant tremor of the hands; a habit of grinding his teeth in a most horrible manner comes on at this time; and his appetite remains good, but the power of swallowing is greatly diminished, and he will often go on cramming food into his mouth until he becomes nearly suffocated. The cause of general paralysis is a subject of discussion. Some authorities have but little doubt that it is generally produced by fast living, excess in wine and in sexual intercourse, particularly the latter. Others deny this, saying that it may arise from extreme mental exertion, greatly prolonged, and point to examples in men of a high order of intellect in which this was the only assignable cause. Whenever it attacks women, which is but rarely, it is nearly always those who have led irregular lives. Dr. Dickson has observed that its subjects are almost invariably men who have had no children. If this be a rule, it may point to a hereditary origin, and also to a tendency to die out. He also inclines to the opinion that the excesses of the patients are more to be regarded as evidences of the disease than as causes.—The insanity which accompanies true epilepsy, and which is known as epilep-

tic insanity, has of late years received much attention, and many remarkable relations have been established between it and other diseases and insanity, especially that form called impulsive insanity. The tendency to epilepsy is hereditary, although it may be produced by blows on the head and other injuries to the brain. It has been found to have strong relations to paralysis, to chorea, and also to phthisis, which are indicated by the fact that children of tuberculous parents may inherit epilepsy, chorea, or paralysis, and *vice versa*; or insanity in offspring may follow these diseases in parents. These diseases may also follow each other in the same individual, an attack of mania appearing in place of epilepsy, the latter, however, being the primary disease. The investigations of Dr. Echeverria have aided in establishing many important facts in regard to the subject, which had previously received the attention of Delasiauve, Morel, Falret, Baillarger, Trousseau, and others. They comprised the examination of more than 700 epileptics, embracing a period of over 13 years. The recorded cases number 532, of which 267 were cases of epileptic insanity, comprising 141 males and 126 females. Out of these the causes were distinctly ascertained in 123 males and 104 females. Insanity, paralysis, or epilepsy occurred among the ancestors of 37 males and 46 females; among the ancestors of the 37 males there were 11 cases of phthisis, and among those of the 46 females there were 13 cases of phthisis. He found that epileptic insanity may have an intermittent, remittent, and a continuous form; the intermittent being characterized by periodical attacks of variable regularity, the remittent having only partial recovery of intellectual soundness between the epileptic paroxysms and maniacal attacks, and the continuous form presenting a permanent and unmodified condition of insanity. Dr. Echeverria does not find that the *petit mal* and the *grand mal* of epilepsy exercise so different an influence upon the violence of the succeeding maniacal attacks as has by some been supposed. The acts of the epileptic insane are always sudden and instantaneous, and beyond the control of the will; but it must not be assumed that the mania which causes the acts is itself instantaneous. He thinks that most of the cases of *mania transitoria* are those of epilepsy or epileptic insanity. Epileptic insanity is of a violent and dangerous character, with strong homicidal tendencies, and is remarkable from the fact that the patient during his maniacal excitement, which may last for hours, and during which he may be wandering around, is wholly unconscious. (See also Maudsley, "Responsibility in Mental Disease," 1874.)—The aphasia which occurs in certain cases of insanity is believed by many to have found an explanation in the experiments of Dr. Ferrier of King's college, London, which are regarded as strong evidence of the localization of cerebral functions; but the correctness of this conclusion is

denied by Dr. Brown-Séguard in a paper read before the national academy of science at Washington in April, 1874.—*Dementia*, or loss of mind, may be primary, or it may be secondary to other forms of insanity, as mania, general paralysis, epilepsy, and more rarely melancholia, and differs from idiocy and imbecility in not being congenital. It is the inevitable stage into which degeneration of brain tissue, if continued long enough, always passes, and is of course incurable, the only treatment being that directed to the general health, and when possible ministering to the comfort of the sufferer.—*Idiocy and Imbecility*. The great difference between these conditions is, that though they are both congenital, the subjects of the former have badly shaped and deficiently developed brains, while those of the latter are usually well shaped, but fail in consequence of congenital pathological conditions similar to those found in dementia. This condition is to a certain though less extent also found in idiots, but many of them are more susceptible of mental cultivation than imbeciles, because the brain of the idiot may be somewhat developed by exercise. (See IDIOCY.)—*Pathology of Insanity in general*. The subject of an attack of acute mania may die in a week from the commencement. A post-mortem examination shows the cerebral membranes congested; the sinuses and the veins of the pia mater may be full of blood, and there may be effusion of serum beneath the arachnoid and the serous membrane. In those who have had previous attacks or who have been partially insane there is often thickening of the bones of the cranium, with adhesion and thickening of the dura mater, indications of a chronic inflammatory condition. The brain will present discolored patches of a pink or purple hue, and also softening. The cells, nerve tubes, and connective areolar tissue may also be found more or less changed. Blood cysts are often found in the cavity of the arachnoid, and extravasated blood on the surface of the convolutions and in the cerebral substance. In cases of chronic mania and dementia there are usually more definite changes. The nerve cells are altered in character, and the nerve tubes leading from them are shrunken and sometimes disconnected. The inferior tissues are increased, and abnormal tissues take the place of those that are healthy, interfering with the functions of that which remains. The wasting of the brain is an important pathological condition. There is a loss of substance, the brains of the insane weighing less in proportion to the cavity of the cranium than in other cases. Dr. Lockhart Clarke has pointed out peculiar and numerous cavities in the white substance of the convolutions and of the optic thalami of the brains of chronic maniacs and the demented, and also in those who have died of general paralysis. These cavities are generally regarded as widened perivascular spaces, formed by the dilatation of the perivascular canals which surround the blood ves-

sels (probably the adventitious tunic of Virchow). They are called perivascular cavities, and present the appearance of holes seen in Gruyère cheese. They are generally empty, having smooth walls, without any lining membrane, but some of them containing the vestiges of blood vessels, with a few granules of hæmatoïdine. Drs. Batty, Tuke, and Rutherford have also observed holes differing somewhat from these, which, from their ragged character, they regard as produced by a solution of continuity of brain tissue, or to extravasation and subsequent absorption of blood. The cells of the corpora striata and other nerve centres, and of the convolutions, are found in a state of pigmentary degeneration, and sometimes in place of this fatty degeneration. Rindfleisch, Rokitansky, Wedl, Tuke, and Rutherford have pointed out hypertrophy of the connective tissue in long standing cases of insanity, and particularly in the cortical layers of the brain in general paralysis. Increase of connective tissue was at one time thought to be peculiar to general paralysis, but it is now known to be common to dementia following chronic mania, as well as that which is consecutive to syphilis and in congenital idiocy. Schroeder van der Kolk found dark pigmentary degeneration in the ganglionic cells of the hypoglossal nerve, in a case of dementia after mania, where there was partial paralysis of the tongue. Pigmentary changes of a like nature have been found in the retina, in what is called *retinitis pigmentosa*; and it is an interesting fact that they occur in members of the same family and where there is common deficiency of development. A pathological condition has been found in general paralysis by Drs. Poincari and Henri Bonnet, which it is thought will throw much light on the nature of this peculiar disease. They have found brown pigmentary degeneration in the ganglionic cells of the whole chain of the great sympathetic nerve, to a degree far greater than in other cases. In the cervical and thoracic ganglia they found a substitution of adipose cells for nerve cells, and they are led to believe that this is the starting point of the disease. A remarkable morbid appearance sometimes found, called the insane ear, or *hematoma auris*, caused by an effusion of blood between the perichondrium and cartilage, which without bursting shrinks away and leaves the ear shrivelled, is a peculiar and it is thought certain evidence that the person is or has at some time been insane. The subject received particular attention from Dr. E. R. Hun while special pathologist to the New York state lunatic asylum at Utica; and from his investigations, which were published in the "American Journal of Insanity" for July, 1870, he established the following general conditions. Preceding the appearance of the tumor, one (rarely both) of the ears becomes red and swollen, the face and eyes of the patient at the same time indicating strong determination of blood to the head. Sometimes,

however, the redness is absent, while the tumefaction is caused by an œdematous state of the auricle. In the course of a few hours, or it may be several days, an effusion of blood appears on the concave surface of the auricle, varying in size from a bean to a hen's egg, in the latter case obliterating the natural ridges and depressions. Although apparently hard and unyielding, a careful examination detects a feeling of fluctuation and sometimes slight crepitation, supposed to be owing to the breaking up of blood clots. The skin is smooth and distended, and of a purple color, except that of the lobe, which is unchanged. If the skin is ruptured, clotted blood escapes; and if let alone, the opening closes and the sac refills. If kept open, however, a sero-purulent discharge takes place, which may continue for a long time, exudation of plastic lymph occurring in the mean time, uniting the walls of the cavity, and by subsequent contraction of the cicatrix producing the peculiar shrivelled appearance which is the sequence of the acute affection. When the sac does not become ruptured, much less deformity results. Examinations of the pulse of the insane have revealed some remarkable characteristics, which are described in the article PULSE.—*Enumeration of the Insane*. The following table of the insane in various countries, compiled from the report of Dr. E. T. Wilkins, commissioner in lunacy for the state of California, made in December, 1871, contains the most complete synopsis of information that can be procured at the present time:

COUNTRIES.	Date of information.	No. of institutions.	No. of insane in institutions.	Total number of insane.	Total population.

INSECT FERTILIZATION. It has long been a matter of common observation that many plants, with their stamens and pistils in separate flowers, whether monœcious or diœcious, depend upon insects for their fertilization; the insects, in their visits from flower to flower in search of honey, evidently bring the pollen from the anthers of the staminate to the stigmas of the pistillate flowers, as every gardener knows who has tried to keep his varieties of melons and other plants of the same family in a condition of purity. Darwin, in his work "The Fertilization of Orchids" (London, 1862), showed that many perfect flowers, with their pistils and stamens in close proximity, are so

Section of Iris.

constructed that the pollen can never without extrinsic aid reach the pistil of its own flower, or serve to fertilize that of any other flower. He showed that there is a complete provision that the flowers of many orchids should never

be fertilized by their own pollen—in other words, that in-and-in breeding is impossible—and arrived at the conclusion that cross fertilization is necessary among flowers of the same species, in order to promote the greater vigor of the whole, and to prevent the perpetuation and fixation of individual peculiarities. This subject has since received the attention of many close observers, and many interesting facts have been established. It has been found that in perfect or hermaphrodite flowers, which were supposed to be especially arranged for self-fertilization, the stamens and pistils, while close together, are really so placed with reference to one another that self-fertilization is almost impossible, and unless insects come to their aid no seed will be produced. It is another interesting point that flowers needing the aid of insects are supplied with an attraction for them in the form of nectar. In most flowers the pollen is a fine dust which readily adheres to whatever it touches, and the contrivances to prevent the pollen of a flower from reaching its own pistil are no more varied and interesting than those which insure that a bee or other insect shall come in contact with this pollen and carry it off upon its body. To illustrate this, an engraving (from Gray) of a section of the flower of a common iris or flower-de-luce will serve. In this there are three recurved outer petals and three erect inner ones, united below in a tube; the pistil has three styles, which are broad, petal-like, and notched at the top; each style bears just below the notch a stigma, which is a thin plate projecting like a little shelf, the upper side only of which is stigmatic, or capable of receiving pollen; below each stigma is an anther, as seen in the engraving. Here the stamen and pistil are not only in the same flower, but in actual contact; yet while everything appears favorable for the pollen to reach the stigma, it cannot do so of itself, for the anther or pollen case has the openings through which it discharges pollen turned outward, and the stigma is above and its receptive portion turned away from the anther. When an insect visits this flower, it can only get at the honey by crawling in under the petal-like style, and in so doing, as well as in making its exit, it must rub against the anther and become dusted with pollen; when the insect thus charged with pollen goes to another flower, it must, in its attempts to get under the style to reach the honey, dust some of its pollen upon the upper surface of the shelf-like stigma. To explain the many ways in which this plan is varied would require a volume; the curious modifications of it in only a portion of a single family, the *orchidaceæ*, fill a book of over 350 pages. The common barberry has irritable stamens, and the laurel (*Kalmia*) has its stamens bent like a spring, the anthers being caught in notches in the corolla, but when disturbed the bent filaments spring toward the pistil with force. These were both regarded as admirable

contrivances for bringing the pollen in contact with the stigma, but closer observation has shown that these sensitive stamens scatter their pollen rather on the insect which irritates them than on the pistil of their own flower. In order to insure cross fertilization in many cases, the stamens discharge their pollen before the pistil is sufficiently mature to receive it, or *vice versa*. Dichogamous is the term adopted to express this unequal perfection of stamens and pistils, of which the common plantain (*plantago*) affords an illustration. Flowers alike in all other respects are often dimorphous as to their stamens and pistils; primroses in the garden and the wild bluets (*Houstonia*), so common in spring, furnish examples. In these flowers the corolla has a long tube and an expanded limb. In some of the flowers the stamens appear at the throat of the corolla, while the style is very short; in others the style projects, and the stamens are low down in the tube. In either case self-fertilization is not likely to occur, but an insect with a long proboscis has an ample opportunity to effect cross fertilization. There are also trimorphous flowers, in which there are three kinds of stamens and styles as to length, admirably adapted to secure service from the different kinds of insects that visit them. Sometimes the insects suffer from the performance of this service; the pollen of the milkweeds (*asclepias*) is in waxy, pear-shaped masses, joined in pairs with an adhesive attachment to the little stalk which unites them. Did not the legs of the insects in search of nectar come in contact with this adhesive attachment, and by its means draw the pollen masses from their pouches, the pollen could never reach the stigma; it often happens that bees have their legs so encumbered by these adhering pollen masses, that when they reach the hive they are unable to climb upon the comb, but fall down and perish on the bottom of the hive. Some interesting experiments show that in many flowers where there is evident provision for self-fertilization, the stigma can hardly be impregnated by pollen from the same flower, while it will readily accept that produced by another flower, and that the agency of insects is absolutely essential to the production of seed in quite perfect flowers.—Excellent memoirs on this subject have appeared in "Nature," the "American Journal of Science and Arts," and the "American Naturalist." A useful résumé for young people is given in Prof. Gray's "How Plants Behave" (New York, 1872). The work of Darwin already referred to is admirable as showing how such investigations should be conducted.

INSECTIVORA, an order of mammals, separated from carnivora, feeding wholly or principally on insects, their teeth being studded with sharp points, feet short and plantigrade, often fitted for digging, and with perfect clavicles. The principal families are the hedgehogs, moles, and shrews, which have been described in their alphabetical order.

INSECTIVOROUS PLANTS. In the article *DIONÆA* the structure of the Venus's fly-trap has been described, and the recent discoveries in relation to its action have been briefly stated. The leaves of the *dionæa* present a beautifully designed and most efficient insect trap, and while the fact of its catching insects had long been known and wondered at, it has only within a few years been demonstrated that the plant does not catch insects for amusement, but food. The insectivorous propensity is more strikingly manifested in *dionæa* than in any other plant, and it is provided with a specially devised apparatus for its gratification; but there are other plants which destroy insects, and what is known of *dionæa* has put naturalists upon a course of observation. The *drosera* or sundew, some species of which are found in almost all parts of the world, has its leaves studded with short hairs, each of which is tipped by a little globule of a clear liquid which, though it looks like a drop of dew, is so viscid as to be able to hold fast a small insect that alights upon the leaf. Dead insects upon the sundews have long been noticed, but their occurrence was considered accidental. It is now known that sundews capture insects with a motion quite certain in its results. When an insect is caught by one or more of the sticky hairs, the other hairs upon the leaf incline toward it, and bring so many adhesive points in contact with it that escape is impossible; and the leaf itself curves and partly envelops the prey. In the case of one long, thread-leaved sundew (*D. filiformis*), the leaves actually coil around the insect. As in the case of *dionæa*, the action is excited by a piece of beef as well as by an insect, but to an inorganic substance, as a bit of chalk, it is indifferent. The observations of Mrs. Treat ("American Naturalist," Salem, Mass., December, 1873) show that when a fly is pinned at the distance of half an inch from the leaves, they will bend toward and reach it. The *sarracenia*s or pitcher plants, of which there is one species in the northern states and several in the southern, all have tubular leaves which contain water in which are found great numbers of dead insects. It is known that in some species at least there is near the opening of the pitcher a sweet secretion, which would appear to be placed there for the purpose of attracting flies and other insects; indeed, the whole structure of the leaves of these plants shows that they are designed as insect traps. The water, which in some species may be caught from the rains, is in others secreted by the plant, as the orifice is so covered by a hood that none can fall in; the interior surface of the pitcher-like leaves is mostly covered with fine sharp bristles which all point downward, and render it almost impossible for an insect that is once within to escape; if we add to this the attractive sweet liquid at the mouth of the pitcher, which has been observed in two species, we have a very complete insect

trap; indeed, the large leaves of the species called trumpets (*S. flava*) are said to be used in houses as fly traps. The abundance of dead insects in the leaves of those pitcher plants which are protected by a hood may be cited in evidence that their habitual drowning of them is not accidental, but that the apparatus is intended to capture and destroy them. When the contents of one of these pitcher leaves is examined there are found insects in all stages, from those recently caught to those so far decomposed as to make it impossible to identify them. The leaves of the related California pitcher plant (*Darlingtonia*) are most effective traps; according to Mr. Robinson, the tubular leaves are for a good portion of their length filled with a nearly solid mass of putrescent insects. The opinion that the animal matter thus abundantly secured by these plants serves to nourish them, though not demonstrated, is highly probable.

INSECTS, six-footed articulated animals, the most beautiful, most active, and most highly organized of the invertebrata, in which, anatomically considered, they bear a remarkable analogy to birds among the vertebrates. Like birds they inhabit the air, earth, and water, have an extensive respiratory apparatus, and consequently a higher calorific and motor power than any other invertebrates. The number of species and of individuals is exceedingly great, and their metamorphoses are among the most interesting phenomena in nature. The class of insects includes all articulates having a distinct head, thorax, and abdomen, with antennæ, three pairs of feet, an aerial respiration by means of tracheæ, a feebly developed circulating system, almost all being winged and undergoing transformation. The cutaneous envelope forms a kind of external skeleton, generally of a horny consistence, formed principally of chitine; it is made up of a considerable number of pieces more or less movable on each other, and is frequently provided with hairs, which are sometimes sharp and barbed (as in the processionary caterpillars), producing considerable irritation when introduced into the human skin. The limbs, which are appendages of the thorax, are hollow tubes containing the muscles and nerves for their motion. The first segment constitutes the head, on which are placed the antennæ, the eyes, and the oral appendages. The antennæ are composed of a variable number of joints, generally resembling delicate and flexible horns, plumed, serrated, clubbed, or foliated, according to genera and families; they are principally organs of touch. The mouth in the chewing insects, like the beetles, cockroaches, and grasshoppers, consists of an upper middle piece or *labrum* with a mandible on each side, the latter being very hard, often toothed at the extremity; the *maxillæ* or under jaws are softer and of many pieces, with maxillary jointed palpi, and the central piece is the *labium* or under lip, also supporting jointed palpi. At the base of the

under lip is attached the tongue, which in some is abortive and in others long and changed into a suctorial organ. In the sucking insects the under lip is transformed into a tube, enclosing delicate lancet-like filaments or bristles, modifications of the mandibles and maxillæ; in the *hymenoptera* (bees, &c.) the mouth is intermediate between the chewing and the suctorial, having parts belonging to both; in the *lepidoptera* (butterflies, &c.) the mandibles are very small, but the under jaws are changed each into a semi-canal which may be rolled up spirally. The eyes are either simple or compound, the first occurring chiefly in the larvæ of the metamorphic orders, and the second in perfect insects; some have both kinds in the perfect state, and some adults, larvæ, and pupæ are blind. The compound organ is made up of many simple eyes, each having its cornea, conical vitreous body, pigment, and nervous filament; the number of these facets is sometimes more than 25,000. The simple eyes (*stemmata*) consist of a cornea, a lens lodged in an expansion of the optic nerve, and a surrounding pigment layer; they are placed either on the sides of the head, or in small groups on the vertex. The thorax supports the legs and wings, and consists always of three rings, called respectively *prothorax*, *mesothorax*, and *metathorax*, each bearing on its ventral arch a pair of legs; the wings arise from the dorsal aspect of the two posterior rings. The limbs consist each of a two-jointed hip, a thigh, a leg, and a kind of finger or tarsus of two to five joints terminated by the claws; in the jumpers, like the grasshoppers, the hind legs are very long and muscular; in the swimmers, like the water beetles, the tarsi are flattened, ciliated, and arranged for oars; in the flies, the feet are provided with pads and hooks by which they are enabled to hang suspended from smooth surfaces; the anterior limbs are often enlarged, as in the mole crickets, which dig in the ground, and armed with spines, as in the mantis, which uses them to seize its prey; in some of the butterflies the anterior limbs are mere rudiments, useless as means of progression. The wings are membranous expansions, rendered firm by solid nervures; there are never more than two pairs, and one or the other may be wanting; in the butterfly they are covered with a colored dust consisting of microscopic scales; in the beetles the first pair becomes thick and hard, forming the *elytra*, which cover and protect the second pair; the wings are sometimes half membranous, half corneous, at others divided into barbed plumules, or wanting and replaced by the knob-like balancers. The legs and wings are moved by striated muscles, attached directly to the cutaneous skeleton; those of the wings of the *diptera* have their fibrillæ separable into series of disks, the astonishing rapidity of their movements being dependent on alternate contraction and relaxation. The abdomen is composed of rings

movable upon each other, sometimes to the number of nine; they bear in the perfect insect neither legs nor wings, but are provided with various appendages useful in the economy of the animal, as the delicate bristles of the ephemera, the nippers of the earwig, the spring of the podurella, the sting of the bee and wasp, and the ovipositor of the grasshopper and the ichneumons. Besides the antennæ, the palpi about the mouth, the end of the suctorial tube, the ovipositor, and the feet in some instances, are delicate organs of touch; the tongue, when present, as in bees and flies, is undoubtedly the seat of an acute sense of taste. Though insects apparently perceive by the sense of smell what food is proper for themselves or their young, the seat of this sense has not been satisfactorily determined; Duméril and Cuvier, reasoning from analogy, concluded that it was placed at the openings of the respiratory trachææ; Huber, from his experiments on bees, placed it in the mouth, Kirby in the anterior portion of the head or the nose, and others in the antennæ and palpi. Hearing is acute in many insects; the shrilling of the locust, the tick of the deathwatch, the song of the cricket, &c., would be useless unless they could be heard by their companions; in the *orthoptera* especially an auditory apparatus is connected with the stigmata of the thorax and the anterior legs; the sense has also been placed inward at the base of the antennæ. The sounds of insects are produced by the friction of one part of the external skeleton on another, by the vibration of special organs, or by a particular soniferous apparatus, always due to the action of voluntary muscles and unconnected with the respiratory system; the buzzing of flies seems to depend on the rapid vibrations of the thorax during flight and on the passage of air through the thoracic stigmata, perhaps intensified by the motions of the wings themselves; some beetles produce a sharp sound by rubbing the last abdominal segments against the curved points of the wing covers, or the thoracic rings against each other; the sounds of butterflies and of the death's-head moth are referred to friction of the hips together, and to various causes not at all satisfactory. The nervous system consists of a brain and spinal cord; the former is constituted by the ganglia which embrace the œsophagus, and is situated in the first segment; the spinal cord is made up generally of a double series of ganglia united by longitudinal cords, in number corresponding to that of the segments of the body; the three thoracic ganglia are much the largest, and from them are given off the nerves to the legs and wings. The alimentary canal is generally complicated and more or less convoluted; it consists of a pharynx, œsophagus, first stomach or crop, second or gizzard with muscular walls for trituration, third or chylic ventricle of soft and delicate texture, a small intestine, cæcum, and rectum; as in the higher animals,

it is shortest in the carnivorous families, and very long in the vegetable feeders; it is kept in place by numerous fine tracheæ which envelop its whole extent; in the sucking insects there is only a sucking stomach opening from the œsophagus, into which the fluid food is first taken, as in the first stomach of ruminants. The anus opens on the last segment, except in some non-feeding pupæ, in which both it and the mouth are wanting; the salivary glands are well developed, opening into the pharynx; the villousities of the third stomach seem to secrete a gastric juice, the biliary secretion being poured into this cavity; the office of a liver is performed by cæcal appendages lying upon the ventricle; similar organs on the small intestine sometimes perform the office of a pancreas. An adipose tissue is found in all insects, especially toward the end of the larva state, gradually disappearing in the perfect condition, freely traversed by trachean branches; the fatty contents are intimately connected with the functions of nutrition. The circulatory system consists of a contractile chambered dorsal vessel which serves as a heart, and a cephalic aorta which conducts the blood into the body; the blood moves from behind forward, and passes from the aorta all over the system, forming regular currents without vascular walls, and returning as venous blood to the lateral vessels; the blood is usually a colorless liquid, containing a few small oval corpuscles. Respiration is carried on by a system of tracheæ spread through the entire body, which open externally by stigmata, and admit air either directly or by means of lamelliform or tubular prolongations which have been compared to branchiæ; they divide into branches, gradually becoming smaller, ending cæcally, so that the air passes out by the same way that it enters. The branchial tracheæ are found in certain aquatic larvæ and pupæ, and never in the perfect insect; they do not communicate externally, but the air is received by endosmosis and exosmosis. The stigmata of the pulmonary tracheæ are usually bordered with a fringe of hairs, and can be opened and shut by internal muscles, whose action gives to the abdomen of many insects well marked movements of respiration; there is generally a pair on the upper portion of the interstices between the rings, being wanting between the head and prothorax and the last two abdominal segments; the tracheæ are often dilated into large reservoirs of air. Respiration is very active in insects, and performed by the movements of the abdominal segments; they require a great deal of air, and are very quickly asphyxiated by deprivation of oxygen; though not producing much animal heat ordinarily, sometimes, as in the bees when hived, the respiration is accelerated and their temperature perceptibly elevated. The Malpighian vessels, which were formerly supposed to be biliary, are now ascertained to be urinary organs, secreting uric acid products; they are small convoluted tubes,

yellowish or brownish, and open into the posterior extremity of the stomach. Many insects have secretory follicles just under the skin, whose ducts open between the segments or between the joints of the limbs, or by the side of the anus; the fluid secreted is generally of a disagreeable odor, and sometimes, as in the bugs, very fetid. The females in many of the *hymenoptera*, as the bees and wasps, have a glandular apparatus in the anal region, which secretes an irritating poison introduced into the tissues of their enemies by their hollow stings. Most insects undergoing a complete metamorphosis have in their larva state silk organs, whose secretion they use in the formation of their cocoons and webs; they consist of two long, flexuous tubes on the side of the body, continuous in front with two small excretory ducts opening on the under lip; in a few the silk is spun from a spinneret projecting from the anus; the wax-secreting apparatus has been described under BEE. The sexes are distinct, and the females often differ greatly from the males, as in the glow-worm; among the bees and ants the females are much less numerous than the males, and certain individuals of neither sex, or neuters, do the work and protect the colony. Most insects lay eggs, though a few, like the *aphides*, are viviparous; by means of an ovipositor many introduce their eggs into a deep-seated nidus, in or near which the young can find the food suited for them, almost always different from that required by the parents. There are generally two symmetrical ovaries and testes, situated in the abdominal cavity, and two oviducts uniting into a single one at the posterior end of the body. In their progress to maturity insects change their skins many times, and many of them undergo transformations as singular as those already mentioned in the frogs; on coming from the egg they are very different from their parents and from their pupa forms. Before arriving at their perfect state they usually pass through the larva and pupa form, which may be entirely different, or vary chiefly in the development of wings, according as the metamorphosis is complete or not. Insects with complete metamorphosis when they leave the egg or are in the larva state are more or less worm-like, with an elongated soft body divided into movable rings, normally 13 in number, sometimes with and sometimes without feet; in no respect do they resemble the parents; the eyes are generally simple, and occasionally absent; the mouth is almost always armed with jaws for chewing, even in insects which are sucking in the perfect state; these larvæ are called caterpillars or maggots, according to their size, form, and habitat. After remaining in this state, either in the water, in the air, or under ground, a certain length of time, varying according to the species, and undergoing several moults, rudimentary wings form under the skin, and they change into nymphs, chrysalids, or pupæ; the

larval condition persists sometimes for several months, as from the autumn to the following summer, and in the case of the harvest fly for a much longer period. Larvæ are generally voracious and active, but nymphs are as generally motionless and do not eat; sometimes the larval skin hardens into a shell-like covering for the nymph; at others a thin investing pellicle applied to the body permits the animal to be seen through it. Before undergoing this change the larva often prepares a shelter, making a cocoon of silk secreted by itself; the nymph may be suspended from a twig by silken filaments or concealed in some crevice. In the nymph state growth takes place rapidly, and the form of the future insect is gradually assumed. The metamorphoses are easily studied in the common caterpillars, the bee, the mosquito, the fly, and the silkworm. The life of the perfect insect is short, enduring at most for the summer months, until the work of reproduction is completed; in the *ephemera* the adult state continues for a few hours only. As instances of incomplete metamorphosis may be mentioned the cockroach, the cricket, the grasshopper, and other *orthoptera*, in which the larva differs from the perfect insect principally in the absence of wings. For further details on larvæ and pupæ, the reader is referred to CATERPILLAR, CHRYSALIS, and the various insects in their respective order.—As insects furnish food for a great variety of vertebrate and invertebrate animals, their extermination would ensue were it not for their astonishing fecundity, paralleled only in the case of fishes; a female *termes* (ant) has been estimated to lay about 90,000 eggs in a day; the queen bee deposits between 5,000 and 6,000, the common ant about 1,000 less, the wasp about 3,000; a posterity of 1,000 in one generation is common; in the silkworm the average is 500; the beetles are far less prolific. Réaumur observed 350 young ones developed from the numerous eggs of a moth (*phalæna*), many of which died as caterpillars, so that only 65 females reached the perfect state; these were calculated to produce the following year 22,750, which in the next would produce 1,500,000. A single plant louse (*aphis*), which brings forth a numerous progeny, but only one at a time, according to the above author's calculation, would produce in the fifth generation about 6,000,000,000, the great-great-grandmother laying eggs when the ninth member of her descendants is capable of reproduction, without contact with the male.—The muscular activity of insects is very great, whether in leaping, swimming, flying, digging, or carrying weights; no mammal can leap in proportion so high or so far as the flea, to a distance more than 200 times the length of its own body; no bird has a facility of motion, and a rapidity and endurance of flight, comparable to those of insects. The wings of the butterfly have been found to display the structure ascertained by civil engineers to combine the greatest lightness with the greatest

strength; in the nervure of the wing, as in the strongest beam, the utmost possible material is thrown into the flanges, and the upright support is as thin as practicable; in the hollow nervures we have two flanges connected by the thin membrane of the wing, and the strongest nervure at or near the anterior edge. The apparatus by which many insects walk upon perpendicular surfaces is described in the article FLY. The larva of the ant lion digs its sand pit, and the fossorial wasp a hole for its eggs, in a very short time; a few ants are strong enough to drag from their hill a large caterpillar; a few burying beetles will place a mole under the earth in an hour, a feat equivalent to as many men burying a large whale in the same space of time; the gadfly is faster than the fleetest horse; a humblebee has been known to distance a locomotive going at the rate of 20 miles an hour, and a dragon fly to lead a swallow a weary chase of an hour, and at last escape. The instincts of insects, which sometimes closely border upon intelligence, are very remarkable, and calculated to excite the admiration of the most superficial observer. Insects apparently acquire knowledge from experience, possess the faculty of memory, and are able to communicate their purposes to their fellows; they evince great sagacity in their methods of procuring food and in defending themselves against their enemies; their devices for entrapping prey are very ingenious: to escape their enemies, some feign death, and others conceal themselves, fight bravely with their jaws and stings, and emit a nauseous odor or corrosive juices. As examples of insect instincts we need only mention those of the bee, wasp, and ant in constructing their habitations, of the silkworm, of the caterpillars (like *tortrix* and the clothes moth) which roll up leaves or woolly materials for their protection, of insects which unite in communities for mutual protection and support, and of those which lay their eggs on substances most proper for their young, which they will never see, and which feed on matters entirely different from the food of their parents (as the wasps). In their adaptation of these instincts to accidental circumstances, they approach very near to intelligent acts. Insects have many passive means of avoiding their enemies in the form and structure of their bodies, and in their resemblance in color to the objects on which they live, whether ground or tree, as in beetles, grasshoppers, the mantis, and many bugs living on bark; the larvæ of tortoise beetles are spiny, others are hairy, and consequently avoided by insectivorous birds; hardness of integument and tenacity of life are also important means of preservation. The continuance of the species is secured by the strong sexual impulse, and by the care of the female in depositing her eggs in places where the future welfare of the young will be insured; the life of the insect generally ceases soon after the period of sexual activity;

among the social insects, the young are fed by the neuters and females. For details, see Kirby and Spence's "Introduction to Entomology."—The relations of insects to the rest of organic nature are very interesting and important. Most insects derive their food from the vegetable kingdom, to which they are both injurious and beneficial; by their simple agency not only is a limit set to the increase of plants, but their preservation is due in many instances to insect operations. Myriads of larvæ feed upon the roots, leaves, flowers, fruits, wood, and seeds of plants, not sparing the grains and vegetables most useful to man; the work of Dr. Harris on the "Insects Injurious to Vegetation" gives ample details on this point as far as the northern portion of the United States is concerned, and many of his observations are given in this work in the articles relating to these destructive creatures. On the other hand, fecundation in plants is often promoted by insects; butterflies, bees, wasps, flies, and beetles convey the pollen to the female organs, and thus impregnation is effected in many cases where it would otherwise be unlikely to occur. Insects afford food for each other, for spiders, for many fresh-water fishes, amphibians, reptiles, birds, and mammals; and the last two, with man himself, are infested with many parasitic insects. (See EPIZOA.) The direct advantages derived from insects by man are not a few; many larvæ of beetles, grasshoppers, and locusts, South American ants, &c., are occasionally used as food by various savage tribes; the bee supplies honey and wax, the *coccus* manna and cochineal, the Spanish fly a well known blistering drug, the gall insects a valuable astringent, the silkworm a most valuable and beautiful material for clothing, &c.; and the larvæ of flies and many beetles are useful in removing decomposing animal matters.—Insects are found everywhere, even on the surface of the ocean (*hydrometræ*), but they are essentially animals of the air; though a few may be seen in winter, most are active only in the other seasons; the winter is passed in a state of hibernation, either as eggs, larvæ, pupæ, or in a few instances as perfect insects; those of tropical regions are the largest, most numerous, and most gorgeously arrayed; they have been found within eight degrees of the north pole, but their geographical distribution has not received the attention it deserves; some are restricted within narrow limits, while others exist almost everywhere. Insects of a former geological age are found in amber, a fossil resin, in most cases coming very near existing forms, and sometimes of living genera; the number of species thus found is considerable, and, though pertaining only to such as dwelt in woods or on trees, it may reasonably be concluded that then, as now, the insect world was well filled; the beetles are well represented, the *hymenoptera* very abundant, the *lepidoptera* exceedingly rare, the *diptera* and *neuroptera* very numer-

ous, and the *orthoptera* and *hemiptera* not common. Insect impressions have been described in the calcareous formations, especially such as might have been made by aquatic larvæ and insects; Dr. Hitchcock describes footmarks in the sandstones of the Connecticut valley as having been made probably by several genera of insects; and Prof. C. F. Hartt has discovered near St. John, N. B., fossil remains of insects in the upper Devonian formation, which he considers the oldest known.—For the systematic classification of insects, and the history of the science, see ENTOMOLOGY.

INSESSORES, the perching birds, the most numerous of the class, differing from each other greatly in many respects, but agreeing in having three toes directed forward and one backward, neither armed with talons nor webbed. They have been divided by the German ornithologists into the suborders *strisores*, in which the hind toe may be turned forward, like the humming birds, swifts, and goatsuckers, with a feeble voice; *clamatores*, noisy, like the kingfishers and the flycatchers; and *oscines*, singing birds, in which the larynx has five pairs of muscles for the production of song. The last includes the thrushes, warblers, swallows, mocking bird, nightingale, lark, finches, sparrows, crows, and other birds noted either for their song or powers of mimicry or articulation.

INSTERBURG, a town of Prussia, in the province of East Prussia, capital of a circle of the same name, 53 m. E. of Königsberg, on the railway to Gumbinnen, and at the confluence of the Angerap and Inster rivers, forming the Pregel; pop. in 1871, 7,185. There are manufactories of beet sugar, wool, cotton, linen, earthenware, and leather, and an important trade in corn and linseed. The castle of Insterburg was founded by the Teutonic knights.

INSURANCE, in law, a contract whereby an insurer engages, for a consideration which is called a premium, to insure a certain party against loss of or injury to certain property by certain perils. The word peril here means not the danger but the happening of the event which was feared. When the contract is in writing, the instrument is called a policy of insurance. Marine insurance is the insurance of maritime property against maritime perils. Fire insurance is the insurance of houses or goods against fire. Life insurance (of which accident insurance, of recent origin, is properly a branch) will be separately treated under its own name. I. MARINE INSURANCE was wholly unknown to the Greeks and Romans, and to oriental nations. Chief Justice Coke (6 Rep. 47), about 1588, notices the practice of insurance as a mere novelty, and the first English statute which recognizes it is 43 Elizabeth, c. 12 (1601). But the 66th section of the laws of Wisby (a maritime code published probably about 1250) speaks distinctly of it. Some suppose this to be an interpolation; but it is at least possible that the practice of insurance was

more or less common among merchants centuries before it was recognized by the law. It is, at all events, no older than the late part of the middle ages; and it must be regarded as prominent among the many illustrations of that tendency to association which is at once the effect and the cause of our advancing civilization. By means of insurance the resources of many are aggregated for the protection of each. Merchants become members of what is often called, and by the universal practice of insurance becomes, the mercantile community. Each one pays over a part of his profits, so small as not to inconvenience him, and thus obtains protection against a loss which would crush him; and what he pays helps to form the fund that indemnifies others. Hence, commerce is promoted and developed to an extent far beyond what would otherwise be possible, because enterprises become not only possible but prudent by means of insurance, which without it would be so rash that only the reckless would undertake them. The law of insurance may be learned from the purpose of insurance. Thus, it is easy to say, as some do, that insurers should not be strict in their requirements, nor rest upon technical defences and the letter of the law. But all the losses paid by insurers must be paid out of premiums, or the business of insurance would stop; and these premiums must grow higher as the risk increases; and when they get so high as to be much beyond the actual risk incurred by prudent and substantial men who take care that their ships are what they should be, such men will no longer insure. Then the business of insurance will fall into the hands of the careless and the unprincipled, and then premiums must rise still further, and the mischief in this way confirm and enlarge itself. Instead of being a support to commerce, insurance will then only derange it, and be little better than legalized gambling. Similar principles will be seen, as we proceed, to be applicable to every part of the law of insurance; because the whole effort of the law is to make the business of insurance prudent and satisfactory, for merchants who transact a legitimate business honestly and carefully. Formerly much business was done by individual insurers, or underwriters as they are often termed from their subscribing the policies. Now, however, nearly if not quite all policies of insurance, in this country, are made by incorporated companies. These are of two kinds: 1, stock companies, where the stock is owned by persons who receive the profits (that is, the excess of premiums over losses) by way of dividends; 2, mutual companies, where the profits (deducting only the expense of transacting the business) are divided among the insured, or so applied to reduce the premiums that each insured pays only the equivalent of his actual risk. Some companies which operate on the mutual principle have also a certain amount of capital stock as a basis.—Large volumes are written about the law of insurance.

In this article we shall endeavor to exhibit only a brief and condensed statement of its leading principles. The contract of insurance ought always to be in writing; but it may be binding if only oral, unless the insurers are an incorporated company, forbidden by their charter to insure otherwise than in writing. An agreement to insure, entered and subscribed in the usual way in the books of the insurers, would generally be held to be a contract binding both parties to the terms usual in the common policies of those insurers. And it seems to be the settled law of the United States that a contract is made by letter, when either party, receiving a letter of proposals, puts into the mail an answer of acceptance, without having previously received a letter from the proposing party retracting his proposals. A policy is a very ancient instrument, and is substantially the same everywhere, but with special variations. It is subscribed only by the insurers, but the bargain binds also the insured if he accepts the policy and puts his property at risk under it. A policy may insure A specifically, or A "for whom it may concern," or use other equivalent words; and the effect of these words is to bring within the scope and benefit of the insurance every person interested in the property who authorized the insurance, and who was contemplated by A as being insured; or who, being so interested and contemplated, afterward in good faith adopts and ratifies the insurance. Sometimes the policy defines and exactly describes the property insured; sometimes it leaves this undetermined, but requires that it shall afterward be defined, in writing on the policy, as such or such property aboard of such or such a ship; the latter is called an open or running policy. Alterations made by agreement are valid, and are in practice often made and indorsed upon the policy. But a material alteration by the insured, without the assent of the insurer, destroys all claim against the insurer, and is said to have this effect although made in good faith, and with the expectation of obtaining his consent. An alteration by the insurers without the consent of the insured has no effect whatever. If there be a material mistake in the policy, courts having equity powers will sometimes amend it. A policy of insurance is not negotiable; yet, if transferred for value in good faith, the transfer may be so far valid (if not prohibited in the policy itself) as to give the assignee a right to sue in the name of the insured, or, in some states, in his own name, but always subject to any equitable defences which could be made against the insured. But an assignment or transfer of the property insured, before a loss, without a corresponding transfer of the policy with the consent of the insurers, destroys the claim of the insured, and gives none whatever to the assignee. If a loss has occurred, and a claim to indemnity vested in the insured, he may now transfer this claim. And if the bankruptcy of the insured transfers his property and with it

the policy to assignees, the insurers are still held; and on the death of an insured, the property and policy go to his legal representatives. Whatever is written on the face or back of the policy, and is referred to in the policy as a part of it, becomes a part of it; and so is a separate paper, if distinctly made a part by reference which amounts to an agreement. Policies which insure a person who has no interest in the property are called wager policies. They were formerly permitted, but are not legal or valid now either here or in England; it being a universal rule that the insured must have some interest in the property, and this interest must be at risk. If the policy is what is called an open policy, that is, if the interest be not valued therein, and a loss occurs, the insured proves his interest or the value of the property, and is paid accordingly. But the policy may be what is called a valued policy; that is, A may be insured "\$10,000 on the ship Orion, valued at \$20,000." This binds both parties, unless there be an over-valuation so extreme as to be fraudulent, or to be equivalent to a wager policy. If A is insured as above, and the ship is totally lost, he receives \$10,000; but if the ship is partially lost, or injured to say one half of her value, then he receives \$5,000; because by causing himself to be insured only half of her agreed value he is considered as standing his own insurer for the other half. But if he be insured a round sum, without any valuation, he will receive the whole amount insured, provided he can show that he has lost so much by a peril insured against.—The subjects of marine insurance are four: the ship, the cargo, the freight which the ship may earn, and the profits upon the cargo. Either may be valued; but it is common to value a ship, and not so common to value either of the other interests. If goods are valued, it is perhaps for the purpose of insuring the profits, by including them in the valuation of the goods, without insuring the profits under that name. It is not very common to insure profits by themselves; but when this is done, they are usually valued, although this is not necessary. If valued, and the goods are lost, the English courts require proof that they would have made some profit. In the United States the courts consider the loss of goods as implying the loss of some profits, and the valuation settles the amount.—Any kind of interest will support an insurance, if it be such that a loss of the property will bring on the insured direct pecuniary loss. Any bailee of the property (or one having possession of it) may insure it if he have any interest in it or responsibility for it. If the property be mortgaged, both mortgagee and mortgagor have an insurable interest in it; so have factors on commission (or commission merchants), consignees, agents having possession, or carriers. The owner of the ship acquires an insurable interest in the freight it will carry as soon as he has received the goods of another to be car-

ried, or has purchased goods to be carried in his own ship, or has made a distinct and obligatory contract with some one to ship them, and his vessel is at or on the way to a port to receive them. The contract of insurance is wholly void if the interest insured is illegal; or if a material and inseparable part of the contract or transaction is illegal; or if it distinctly contemplates an illegal use of that which is insured. But by illegal is meant contrary to the laws of the country where the contract is made and is to be enforced. Thus, an insurance in America, to cover goods intended to be smuggled into England, would not be void in America, but would be in England. Some contracts of insurance are prohibited by the mere policy of the law; thus, a mariner cannot make a valid insurance of his wages, because it is important that he should feel the danger of losing them if the ship be lost.—The subject of warranties in marine insurance is very important. These are promises of the insured that certain things exist or do not exist, or shall be or shall not be done; and if the promise is broken the contract is void, whether the promise is material or not, and whether the breach of the promise is the fault of the insured or not. And they must be exactly complied with, though the warranty will be construed reasonably, and according to the usage of merchants and insurers, and the honest and actual intention of the parties. The warranty may be express or implied by law. If express, it must be written on or in the policy, or by distinct reference made a part of it. Any distinct assertion amounts to a warranty; if the ship be described as "the American ship Flying Cloud," this is a warranty that she is American. Express warranties are most usually: 1, of ownership; 2, of national character; 3, of the lawfulness of the goods or voyage; 4, of the taking of convoy; 5, of the time of sailing. There are also some implied warranties; but by far the most important of these is the universal warranty of seaworthiness. Every person who proposes to insurers to insure his ship, engages and warrants that his ship is in every respect in a safe and suitable condition to encounter all common perils and dangers on the voyage or in the place where she is to be while under insurance. The insurers may expressly waive this warranty, but this is very seldom done; and wherever it exists, there it is a condition precedent to the obligations of the insurance; that is to say, if this warranty be not performed or complied with, the insurance never attaches. The insurance is equally avoided by unseaworthiness, although this was unknown, and indeed could not be known, to the insured. Seaworthiness requires reasonable soundness and strength in materials, and a full equipment of all appurtenances and implements which are necessary to the ship, with a proper master, officers, and crew, and proper papers. If the ship is seaworthy at the beginning, so that the

policy attaches, the law may not be quite settled as to the effect of a subsequent unseaworthiness. It certainly has no effect upon a previous loss; and we consider the better rule to be, that it only suspends but does not destroy the insurance. Thus if a ship loses her best bower anchor, this has no effect upon a previous loss, nor upon a loss that occurs before the anchor can be replaced. If the vessel reaches a port where she might replace the anchor, and does not, and sails and meets with a loss, nearly all agree that the insurers are discharged; but some authorities hold the insurers liable for a loss occurring during such an unseaworthiness, if the loss is not caused by it.—Another implied warranty is, that there shall be no false representations, and no concealment of material facts; for if there be either of these, the policy does not attach. In the law of insurance, that is a misrepresentation which, however made, tends materially to obtain for the utterer a contract which otherwise would not be made, or better terms than would otherwise be granted. Concealment is the suppression of a material circumstance, for the same purpose. Such misrepresentation or concealment discharges the insurers, although made unintentionally and only through mistake; but it has not this effect if withdrawn before the policy is made, or if it ceases to be material before the risk begins. If the representation relates to the future, a future compliance with it is as necessary as a present compliance with a present representation. The insured is bound to communicate not only ascertained facts, but all intelligence, and even rumors, if they are such as may reasonably enter into the estimate of the risk; but he is not bound to disclose what are merely his own hopes or fears, nor such matters of general information or public notoriety as are likely to be as well known to one person as to another; nor anything which the insurers already know; nor anything expressly provided for in the policy. A substantial compliance with a representation is sufficient, although it be not so exact as would be required in the case of an express warranty.—As nothing prevents the parties from making what agreement they choose, they sometimes omit, or expressly except, certain risks; or the insured warrants against them, which comes to the same thing. When, as sometimes happens, causes mingle to produce a loss, some of which are insured against and some are not, it may be very difficult to determine whether the insurers are liable. There are many such cases. The general rule is: *Causa proxima, non remota spectatur*. But even then it becomes difficult to know what is a proximate cause, and what is a remote cause. Here also the general rule may be given; it is, that insurers are not liable for any effects of a peril against which they insure, excepting those which are the natural, direct, and immediate effects thereof. One way in which insu-

rers seek to guard against this question, is by having a long list of what are called memorandum articles inserted in their policy, or referred to in it. These are grain, hides, and other perishable things, which are likely to be injured somewhat, either by slight causes, or without external causes; and it is provided that the insurers shall not be answerable for these, unless there is a total loss, or a certain large loss, or unless the loss is caused by stranding; for in either of these events, it will be probable that the loss is caused by a peril insured against.—Another implied warranty of the insured is, that there shall be no deviation; which means, primarily, that the ship shall go by the direct and usual course to the place whither she is bound. It means also, by construction and usage, not only that there shall be no departure from the proper course, but no unnecessary delay, or, more extensively, no material departure from or change in the risks insured against, not justified by a good cause. Nor need this change increase the risk, for the parties have a right to hold each other to their agreement. There may be deviation while a ship is in port, or where no particular voyage is indicated, the insurance being on time; and the rule concerning deviation, like nearly all those of the law of marine insurance, is equally in force in the lake and river navigation of this country as in its ocean commerce. The effect of deviation is to discharge the insurers altogether from all subsequent risks. If, when a deviation ceases, all subsequent risks are precisely the same as they would have been had the deviation not taken place, the obligation of the insurers might revive; but this can rarely be the case. There are cases where a slight deviation discharges the insurers; but it must have some reality and effect. Delay in commencing or in prosecuting a voyage may be a deviation. Going into a port out of the natural and proper course is certainly one. Liberty is often given in the policy "to enter" such a port, or "touch at," or "stop and trade at," or otherwise as the parties may agree; but such a liberty is usually construed very strictly. A deviation does not discharge the insurers, unless it be voluntary. Any necessity, as for repairs or provisions, or to save life, or to avoid a peril, justifies so much deviation as it requires. A mere intent to deviate has not the effect of deviation. Thus, for example, if a vessel sails from New York insured on a voyage to New Orleans, intending at a certain point in her course to bear away for Havana, and is lost before she bears away, the insurers are held.—We have already said that the consideration for the contract of insurance is called the premium; and this is a small sum of money, for which, in this country, the insured or his agent usually gives his note when the policy is made and delivered, which is called the premium note. This premium is never due in fact until it is earned by the risk, for insurance against which the pre-

mium is paid. If this risk never takes place, the promise to pay the premium cannot be enforced; and if it has been paid, the insurers must repay it. Hence it is always in the power of the insured to cancel the policy before the risk attaches, by refusing to put his property under that risk. But unless the voyage be abandoned, a notice of his wish to cancel the policy has no effect. If the whole risk attaches to the whole property for any time whatever, no part of the premium is returnable. If the risk attaches to a severable part of the property only, a proportional part only of the premium is earned, and the remainder is returnable. Clauses are sometimes inserted in policies defining certain contingencies upon which the premium is returnable in whole or in part.—The property insured should be described sufficiently to secure its identification; but the interest of the insured need not be described, as whether it is all, or half, or a quarter, or that of an owner, a mortgagee, or a factor. Insurance on a ship covers all the implements and appurtenants actually and properly used for her navigation, although not strictly necessary. An open policy on the ship does not cover the freight; but it is common to cover the freight by a valuation of the ship. One who owns both ship and cargo may insure his "freight," and thereby cover what his ship would earn by carrying for another owner that cargo for the same distance.—The insurers are never responsible for the acts of the insured, or for the direct and immediate consequences of those acts; but they may be for the consequences of the acts or omissions of the master and crew, although they are the servants of the owner, but not if their conduct was in compliance with the owner's orders or instructions. It may be stated as a universal rule, that the insurers are liable only for extraordinary risks; for the seaworthiness of the ship implies her competency to meet safely all ordinary risks. Hence they are not liable for any loss which shall be attributed to wear and tear, or ordinary breakage. So, too, insurers are never liable for losses which are the consequences of inherent defects or qualities of the property insured, unless these are made active and destructive by a peril insured against, as where hemp rots or lime takes fire from being wet by the effect of storm or wreck. If the losses occur by contraband trade, or a violation of the law of foreign countries, this, we have seen, does not discharge the insurers on the ground of illegality; but it does discharge them as a risk they never undertook, unless the insured had previously to the insurance informed them that the goods or ship would undergo this risk, or the insurers knew this otherwise.—American policies commonly enumerate the risks against which the insurance is made. They are usually perils of the sea, fire, barratry, theft, piracy, arrests, and detentions. A general clause, "all other perils," is usually added, but is restricted by the enumeration. Of these perils, the first, "perils of the sea," is by far the

most important, and would of itself include some of the others. It covers in general all loss or damage arising from extraordinary action of wind or sea, or from inevitable accidents arising from navigation. But no natural loss, as for example the destruction of a ship through leakage caused by worms, is a loss by a peril of the sea. Collision is a peril of the sea. The rule of the sea is, that when two ships collide, if neither is in fault, the loss rests where it falls. If one alone is in fault, the whole loss rests on him. If both are in fault, the common law courts let the loss rest where it falls; but the courts of admiralty divide the loss equally between the parties. For the loss a vessel suffers by collision, her insurers are answerable. It has been held that they were liable for what the vessel they insure had to pay because in fault; but the later and the better rule limits their liability to the loss actually sustained. To bring a loss within the clause of "theft or piracy," it is said that there must be violence, and that the thieves must not be the crew, unless they are in mutiny; but this is not certain, and it is now common to use the phrase "assailing thieves," in order to limit the liability of the insurers to a loss from violence from without the ship. What is barratry has been much disputed. It is an ancient maritime term, and may perhaps be best defined as any wrongful act of the master, officers, or crew, done against the owner. If it be a wrongful act, against him in fact, it may be barratry, although mistakenly intended for his benefit. But it must be against the owner of the ship, and is not barratry as against other parties if the act be done by the owner's command or with his consent. In American policies it is now common to add after the word "barratry" the words, "if the insured be not owner of the ship." The effect of this is, that ship owners are not insured against barratry, but shippers of goods are; and the reason is, that insurers are willing to insure shippers of goods against the misconduct of those they do not appoint, and cannot control, but are not willing to insure ship owners against the acts of their own servants.—The termini of the voyage must always be definitely stated (if the insurance be not on time), not only to determine whether there be a deviation, but also to show whether any loss that occurs takes place within the policy. It is important therefore to know precisely when the insurance begins and when it ceases. By the words usually inserted, "lost or not lost," the insurers make themselves responsible although the property be at that time wholly lost, provided the insured does not know it, or makes known all he knows about it. Insurance "at and from" a place begins when the property is there in a safe condition. Insurance "from" a place begins when the ship sails. English and American insurers now usually insert a clause in all voyage policies, that the insurance continues "until the ship be arrived and moored 24 hours in safety." This means safe-

ty from the perils insured against, and not the local ones of the port or place, as unsafe mooring, &c.; as otherwise it could not cease while she lies there. The insurers are answerable if the loss occurs after the policy expires, provided it be the direct, immediate, and inevitable effect of an injury received at a time when the policy attached, from a peril insured against.—The loss may be total or partial; and a total loss may be actual or constructive. An actually total loss occurs when the ship or goods are actually submerged, or destroyed by fire or some other peril, so that no part of them of any value survives and is recoverable. A constructive total loss, or, as it is sometimes called, a technical total loss, is one in which valuable portions of the property survive, but are transferred to the insurers by abandonment, so that the whole property passes out of the possession of the insured, and the insurers pay for the whole, and hold the salvage (or property saved) as their own. By the established usage of this country, confirmed by abundant adjudication, the insured has a right to abandon, and thus convert a partial loss into a total loss, whenever the partial loss exceeds one half of the value of the property insured. But our policies now generally contain the clause that there shall be abandonment only when the partial loss exceeds 50 per cent., estimated as a partial loss. This means, after a deduction of one third off. For it is one of the practical rules to which merchants have come, that in every case of partial loss one third shall be allowed as the benefit conferred by the new materials of repair; or, in the common phrase, "one third off, new for old." Thus, if a new vessel sails to-day, and to-morrow loses her masts and rigging so as to require that all her top hamper should be replaced, and the insurers pay the cost of this, the owners gain nothing. But if the same ship, after spars and canvas are nearly worn out, meets with the same disaster, and new ones are supplied, and the insurers pay the cost, the insured gains nearly all that he receives, for he lost very little by the disaster. Merchants and insurers, instead of trying to determine the proportion in each case, wisely conclude that the average, one third off, meets all cases fairly. Applying this to the case of constructive total loss, it is plain that a partial loss, to justify abandonment, must be more than 75 per cent. (For the loss of a ship by the sale of the master, in a case of strict necessity, see SHIPPING.) Whether the property insured be ship or cargo, it is the universal rule that a loss where anything is saved cannot be made total, excepting by transfer of salvage by abandonment to the insurers; and the same rule applies to all claims, rights, or interests in, to, or about the property, remaining in or accruing to the insured. Thus, if the insured lose by jettison or otherwise so as to acquire a claim to general average contribution, this claim must be transferred; and if the insured have to pay a general average

contribution caused by a loss insured against, the insurers must repay it. (See AVERAGE, and SHIPPING.) There is no especial form of abandonment; but it must be made by the insured without any unnecessary delay, immediately upon learning the loss, and in terms distinctly indicating the fact of their loss, and their transfer of all salvage by abandonment, and their claim for a total loss. If the abandonment is accepted, it binds the insurers; but if they refuse the acceptance, their refusal cannot impair the rights of the insured. II. INSURANCE AGAINST FIRE. The principles of fire insurance are the same with those of marine insurance, excepting so far as the nature of the property and of the risk causes a difference. It is only these differences that we need to present. Marine insurance is usually effected through a broker; fire insurance usually by the party himself. He generally has to sign a formal application, and answer therein many questions; and the substantial truth of every answer would be taken as a condition precedent to any liability on the part of the insurers. It is common to state in the application, or policy itself, that certain risks are "hazardous," and a scale of premiums is sometimes given for different classes of property; and it is of extreme importance that the insured should not deceive the insurers on this point. But there must be a rational if not a liberal construction of all these rules. Thus, if "cotton in bales" is represented as particularly "hazardous," a policy would not be avoided by the fact that a person insured upon a store and goods had one or two bales there for retail. So if "storing" certain goods demands an extra premium, having a small quantity for home consumption, or even for sale, does not come within the meaning of this clause. If the insured proposes to make any alteration in the premises insured, he should make this known to the insurers, and, if he can, obtain their leave in writing. But we apprehend that mere alterations, however expensive or important, do not of themselves avoid a policy, unless they are such that they increase the risk substantially. While the alterations are in progress, and a new risk exists from them, the underwriters are discharged from liability caused by a loss arising from this risk, but not, we think, if it arises from a cause wholly independent of the risk; and if the alterations are finished, and the risk not altered, they do not affect the insurance. It is usual to provide in the policy, or by the rules of the company, for making necessary or proper repairs. The law of warranty, of representation, and of concealment, is much the same in fire insurance as in marine insurance. But some questions have arisen as to what part of a description is a continuing warranty. If expressly prospective, as that water tanks shall be kept in an upper story, or a certain watch maintained, these of course are continuing promises, and a breach avoids or suspends the policy. So a description that the house is slated

would be a continuing warranty that it should remain slated. But a statement that the house stands "500 feet from any other building" would not avoid the policy, if a neighbor should put up a building within 100 feet of the insured. There seems to be this difference between the two kinds of policies: a breach of warranty avoids a marine policy, however innocent the insured; but it seldom has this effect upon a fire policy, unless there be fraud or other default on the part of the insured. At the time of the insurance, the property must be in existence, and not then on fire, or in immediate danger from fire. Heat alone, however excessive, or however caused, or however destructive, does not make the insurers liable unless there be fire, or ignition. Hence, it is now settled that a loss by lightning is not a loss by fire, unless the property be lost by ignition caused by the lightning. But if there be a fire, usage and the law go very far in holding the insurers liable for the consequences of it. Thus, any loss caused by honest efforts to extinguish the fire, as by water poured upon it, or any loss sustained by removal of the insured goods from a peril of fire, or by the blowing up or tearing down of a building to arrest a fire, would fall on the insurers. But there must be an actual fire, near enough and dangerous enough to justify reasonable men in the measures which have resulted in the loss. While an explosion of or by gunpowder is a loss by fire, an explosion of or by steam has been held not to be so. Though the loss be caused by the negligence of the servants of the insured, the insurers are still held; and so they are if it be caused by his own negligence, unless that be so extreme and extraordinary as to raise a suspicion of, or rather imply, fraudulent intent. That the fire was caused by the insanity of the insured is no defence to the insurers.—Valuation is sometimes made in policies by stock companies upon chattels of uncertain value, as books, plate, or works of art; seldom by these companies on houses; and never upon anything, so far as we know, by mutual companies, for the purpose of determining the amount to be paid in case of loss. If a loss happens, the insured is entitled only to actual indemnity; but a valuation is required by the charters of most companies, that they may not insure beyond a certain proportion of the value, and the valuation for this purpose is usually binding on both parties. Insurers against fire generally stipulate that they may rebuild or repair the premises insured, if they prefer this course to paying for the loss; and they frequently avail themselves of the right. There is not in fire insurance any rule answering to the "one third off, new for old," in marine insurance; nor any usage of making a partial loss total by abandonment, although all insurers who pay a total loss are entitled to all salvage or remains. Nor is there anything of general average known to fire insurance.—As it is deemed especially important in fire insurance to prevent insuring

more than the value of the property, in order to guard against the temptation to burn it for the insurance, policies generally provide in substance and effect that any previous insurance, not made known, shall avoid any subsequent policy; and the law is very strict in construing and applying this rule or provision. It is now common to provide also that subsequent insurance, not made known and assented to, shall avoid the policy. (See LIFE INSURANCE.)

INTEGRAL CALCULUS. See CALCULUS.

INTERDICT, in the Roman Catholic church, an ecclesiastical censure, or penalty forbidding public worship and the administration of the sacraments to certain persons or in certain places. Generally speaking, what the Roman Catholic church considers as the necessary rites of religion were not forbidden, such as baptism, confession, and extreme unction. Indeed, all the sacraments in most cases continued to be conferred privately, the solemn services alone being suspended. The canon law recites three kinds of interdict, local, personal, and mixed. The first directly affected the place, and indirectly its inhabitants, and them only while within its limits. The second affected the persons, who were interdicted the solemn services wherever they might be. The third combined both these effects. In the beginning interdicts were employed by all persons having episcopal jurisdiction, but in course of time their use was restricted to the Roman pontiffs. They were scarcely known until after the Carolingian period, when the interdict became a powerful ecclesiastical weapon for restraining the violence of the feudal nobles. However, one instance of its use occurred in 586, when Queen Fredegonda having caused Prætextatus, bishop of Rouen, to be slain in his own cathedral, Landowald, bishop of Bayeux, with the advice of the local clergy, commanded all the churches in the city to be closed and public services to cease till the instigators and perpetrators of the crime had been discovered. In the 10th century the popes began to have recourse to interdicts in their contests with sovereigns. In 997 Gregory V. laid all France under an interdict because King Robert had married his own cousin, and the king was abandoned by most of his court. The same penalty was inflicted upon the kingdom of England under Stephen (1147) by Eugenius III., under John (1208) by Innocent III., under Henry VIII. (1535) with little effect by Paul III., and under Elizabeth (1587) by Sixtus V. Adrian IV. laid Rome under an interdict for the purpose of driving out Arnold of Brescia. Gregory IX. made use of the same weapon in his quarrel with the emperor Frederick II.; and Paul V. in 1606 laid an interdict upon the republic of Venice in consequence of the passage of certain decrees relating to ecclesiastical matters. The government resisted the promulgation of the bull, and ordered the parochial clergy to continue their functions as usual. From the time of the reformation, local interdicts became rare; personal

interdicts, which are the severest forms of ecclesiastical censure, are still imposed.

INTERLAKEN, or **Interlachen**, a village of Switzerland, in the canton and 26 m. S. E. of the city of Bern; pop. about 1,400. It is celebrated for its charming situation near the left bank of the Aar, in the valley of Bördeli, between the lakes of Brienz and Thun, with a view of the Jungfrau, and in the vicinity of some of the most picturesque scenery in Switzerland. It is the starting point from which the Giessbach fall, the valley of Lauterbrunnen with the Staubbach, and that of Grindelwald with its glaciers, are usually explored by visitors, and is a favorite resort of a great

fence of working men's interests in all countries. It originated at the time of the Polish insurrection of 1863. The London working men sent a deputation to Lord Palmerston, asking for interference on behalf of Poland, and also convoked an indignation meeting at St. James's hall, London, in April of that year. The Paris working men sent over two deputies, Tolain and Fribourg, to this meeting; and from the conferences of these delegates with the leaders of the London working men sprang the idea of establishing the international association. A few weeks later George Odger, an unsuccessful working men's candidate for the house of commons, drew up a manifesto which was

translated into French and spread among the working classes of the continent, inviting them to send delegates to a great inaugural meeting in the autumn holiday season (September, 1864). This gathering, which took place at St. Martin's hall, was largely attended by working men of nearly every European country, and presided over by Prof. Edward Spencer Beesley. A general manifesto and the statutes, both drawn by Dr. Karl Marx, were approved for publication; the association was declared established, some funds were collected, a provisional committee was appointed, and Mr. Odger elected president of the association. Soon, however, this office having been declared incompatible with republican theories, the

Interlaken—the Jungfrau in the distance.

number of foreigners in summer, especially English. The village consists mainly of a line of grand hotels and numerous lodging houses, in front of which runs a magnificent avenue of huge walnut trees. Within a short distance of Interlaken are the old castle of Unspunnen and the ancient village of Untersean. In 1859 the innkeepers established a *Kursaal*, like those at the German baths, with ball, concert, and reading rooms; but the Bernese government interdicted gaming. In the season, from June to October, as many as 25,000 persons have visited Interlaken.

INTERMITTENT FEVER. See **FEVERS.**

INTERNATIONAL ASSOCIATION, an association of trades unions, designed for the mutual de-

presidency was abolished, a chairman being elected at every weekly meeting of the general council, and Dr. Marx became the leading spirit of the association. The first continental strike in which the aid of the general council was appealed to and granted was that of the Leipsic compositors and printers in April, 1865. But the statutes of the association were not considered finally established until the first congress at Geneva (1866) had given them a definitive sanction, for three rival programmes were brought forward: that of Mazzini, highly centralized, strongly conspiratory, and dealing much more with politics than with labor and capital; a wild and desultory one of the Russian Bakunin; and the radical and revolution-

ary but business-like one of Karl Marx. The last met with little opposition, and the following were declared by the first general congress of Geneva to be the rules of the "International Working Men's Association:—"

Considering that the emancipation of the working classes must be conquered by the working classes themselves; that the struggle for the emancipation of the working classes means not a struggle for class privileges and monopolies, but for equal rights and duties, and the abolition of all class rule; that the economical subjection of the man of labor to the monopolizer of the means of labor, that is, the sources of life, lies at the bottom of servitude in all its forms, of all social misery, mental degradation, and political dependence; that the economical emancipation of the working classes is therefore the great end to which every political movement ought to be subordinate as a means; that all efforts aiming at that great end have hitherto failed from the want of solidarity between the manifold divisions of labor in each country, and from the absence of a fraternal bond of union between the working classes of different countries; that the emancipation of labor is neither a local nor a national, but a social problem, embracing all countries in which modern society exists, and depending for its solution on the concurrence, practical and theoretical, of the most advanced countries; that the present revival of the working classes in the most industrious countries of Europe, while it raises a new hope, gives solemn warning against a relapse into the old errors, and calls for the immediate combination of the still disconnected movements: For these reasons, the first international working men's congress declares that this international association and all societies and individuals adhering to it will acknowledge truth, justice, and morality, as the basis of their conduct toward each other, and toward all men, without regard to color, creed, or nationality. This congress considers it the duty of a man to claim the rights of a man and a citizen, not only for himself, but for every man who does his duty. No rights without duties, no duties without rights. And in this spirit they have drawn up the following rules of the international association: 1. This association is established to afford a central medium of communication and co-operation between working men's societies existing in different countries and aiming at the same end, viz.: the protection, advancement, and complete emancipation of the working classes. 2. The name of the society shall be "The International Working Men's Association." 3. The general council shall consist of working men belonging to the different countries represented in the international association. It shall from its own members elect the officers necessary for the transaction of business, such as a president, a treasurer, a general secretary, corresponding secretaries for the different countries, &c. The congress appoints annually the seat of the general council, elects a number of members, with power to add to their numbers, and appoints time and place for the meeting of the next congress. The delegates assemble at the appointed time and place without any special invitation. The general council may, in case of need, change the place, but has no power to postpone the time of meeting. 4. On its annual meetings, the general congress shall receive a public account of the annual transactions of the general council. In cases of urgency, it may convoke the general congress before the regular yearly term. 5. The general council shall form an international agency between the different co-operating associations, so that the working men in one country be constantly informed of the movements of their class in every other country; that an inquiry into the social state of the different countries of Europe be made simultaneously, and under a common direction; that the questions of general interest mooted in one society be ventilated by all; and that when immediate practical steps should be needed, as, for instance, in case of international quarrels, the action of the associated societies be simultaneous and uniform. Whenever it seems opportune, the general council shall take the initiative of proposals to be laid before the different national or local societies. To facilitate the communications, the general council shall publish periodical reports. 6. Since the success of the working men's movement in each country cannot be secured but by the power of union and combination, while, on the other hand, the usefulness of the international general council must greatly depend on the circumstance whether it has to deal with a few national centres of working men's associations, or with a greater number of small and disconnected local societies, the members of the international association shall use their utmost efforts to combine the disconnected working men's societies of their respective countries into national bodies, represented by central national organs. It is self-understood, however, that the application of this rule will depend upon the peculiar laws of each country, and that, apart from legal obstacles, no independent local society shall

be precluded from directly corresponding with the general council. 7. The various branches and sections shall, at their places of abode, and as far as their influence may extend, take the initiative not only in all matters tending to the general progressive improvement of public life, but also in the foundation of productive associations and other institutions useful to the working class. The general council shall encourage them in every possible manner. 8. Each member of the international association, on removing his domicile from one country to another, will receive the fraternal support of the associated working men. 9. Everybody who acknowledges and defends the principles of the international working men's association is eligible to become a member. Every branch is responsible for the integrity of the members it admits. 10. Every section or branch has the right to appoint its own corresponding secretary. 11. While united in a perpetual bond of fraternal co-operation, the working men's societies joining the international association will preserve their existent organizations intact. 12. Everything not provided for in the present rules will be supplied by special regulations subject to the revision of every congress.

At this congress of Geneva, also, the questions of the limitations of the working day, of juvenile labor, of co-operative labor, of trades unions, and of a statistical inquiry into the situation of the working classes, had been discussed in such a way as to attract the general attention of the European governments. The French government assumed a very hostile attitude toward the society, and the minister of police, M. Pietri, began not only to prosecute its members, but to accuse them of being connected with all the assassination plots which he constantly pretended to discover in France. This policy only helped the international by rendering the association both more popular with the working classes and more formidable in the eyes of capitalists. In the beginning of 1867 the bronze workers of Paris, about 5,000 in number, struck; and as the strike was firmly kept up by money sent over by the English members of the association, the employers yielded. On the other hand, the great strike of the London tailors in the summer of the same year was largely supported by contributions from Germany, France, Belgium, and Switzerland. The association also helped the great strike in the building trade at Geneva in 1868, so that it was carried through to the satisfaction of the working men concerned. In England, however, where trades unions were already in a much more flourishing condition than on the continent, the main activity of the association consisted not so much in the supply of pecuniary means as in preventing the importation of cheap continental workmen into the British market. Formerly, when a strike took place, the English employers had the facilities for bringing over German, Belgian, and French workmen, and their mere threat of doing so sometimes put an end to the strike. But from the establishment of the international the importation of foreign labor became very difficult, if not impossible; for the moment a strike or lock-out occurred in any of the affiliated trades, the correspondents of the association on the continent were ordered to warn the workmen of their respective localities against concluding any contract with the British employers. The next congress was held at Lausanne in September, 1867. In August of the

next year 122 branch societies of middle and south Germany held a meeting at Nuremberg and joined the association in a body. The third general congress, held at Brussels about a month later (September, 1868), was probably the greatest success of the association, not only in the number of delegates attending it, but also in the importance that was given to the gathering by the leading journals. From the autumn of that year formidable strikes and disturbances occurred all over Europe until the beginning of the Franco-German war; among these were the cotton-spinners' strike at Rouen; the St. Etienne affair, in which more than 50 working men were killed by the troops; the strike at Le Creuzot; the monster disturbances at Vienna, in which more than 50,000 men took part and were dispersed by military force; and innumerable minor strikes in every European country and in almost every trade. At the fourth annual congress, held in Basel in September, 1869, at which a delegate from America was present, it was decided that the next annual gathering should take place in Paris in September, 1870. The war prevented the meeting, and seems to have inflicted a death-blow on the international, by weakening the radical party both in France and in Germany. At all events, the congresses, the general council, and the association itself were not heard of for 18 months, except in their manifestoes protesting against the savagery of warfare and defending the Paris commune. After that and some disagreements at a congress assembled at the Hague, Dr. Marx withdrew from the association, and the whole establishment went to pieces. But it must not be inferred that the theories of the international have also been abandoned. The various branches of trades unions were trained and made acquainted with each other during its five years' existence, and they are now quite capable of sustaining themselves, supported and informed as they are by the various organs of their party. The number of these journals on the continent is 29. The most important of them are: the *Volksstaat*, published at Leipsic; *Proletarier*, Munich; *Volksfreund*, Brunswick; *Volkswille*, Vienna; *Arbeiter-Zeitung*, Pesth; *Werkman* and *Asmodee*, Amsterdam; *Toekomst* and *Vryheid*, the Hague; *Vorbote* and *Egalité*, Geneva; *Arbeiter*, Basel; *Tagwacht*, Zürich; *Solidarité*, Neufchâtel; "Cause of the People" (in Russian), Geneva; *Internationale* and *Liberté*, Brussels; *Werker*, Antwerp; *Mirabeau*, Verviers; *Federacion*, Barcelona; and *Solidaridad*, Madrid. In the United States we know only of the "Workingmen's Advocate" of Chicago and Cincinnati, and the *Arbeiterunion* of New York, as accredited organs of the association.—The gist of all the theories of the internationalists is this: Wages-paid labor must pass away, as serf labor and slave labor have passed away, and must give place to associated labor, which is to be developed to national dimensions and fostered by national means. No

man has a right to call anything his own which he has not produced by his labor.—See the annual reports published in London; also an article by Prof. Beesley in the "Fortnightly Review" for 1870, and "History of the International," translated from the French of E. Villard by Susan M. Day (New Haven, 1874).

INTESTINE, the portion of the digestive apparatus situated below the stomach, divided into the small and large intestines. The former includes the duodenum, jejunum, and ileum; the latter the cæcum, colon, and rectum. Many of the details on these organs have been given in the articles ALIMENTARY CANAL, CÆCUM, COLON, and COMPARATIVE ANATOMY, and need not be here repeated. Next below the stomach comes the duodenum, the largest portion of the small intestine, about 12 in. long, receiving the ducts from the liver and pancreas, and furnished with numerous circular internal folds of mucous membrane (the *valvulæ conniventes*); above it is in contact with the liver and gall bladder, in front with the stomach and arch of the colon, and behind with the spinal column, right kidney, vena cava, aorta, and diaphragm; its arteries come chiefly from the superior mesenteric, and its nerves from the solar plexus. The jejunum and ileum, which follow, have no distinct line of separation, and may be described together as a canal four or five times as long as the body, arranged in numerous folds or convolutions, freely movable in front and on the sides, and attached to the mesentery behind; the upper portion is called jejunum from its being generally found empty. In front these are in relation with the omentum and the anterior abdominal wall, behind with the spine, and in various places with the large intestine; internally the structure resembles that of the duodenum, the valvulæ diminishing gradually from above downward; the mucous membrane is studded with glandular follicles, and contains also the patches of Peyer, the seat of lesion in typhoid fever. Of the large intestine the only portion to be alluded to is the rectum, the terminal portion, ending in the anal opening protected by sphincter muscles; it lies in the concavity of the sacrum, is cylindrical, mostly on the median line, and somewhat dilated at the lower end; its principal relations in both sexes are with the genitourinary organs. Internally it presents longitudinal and parallel folds, with transverse semilunar wrinkles forming sacs in which faecal matter is often lodged for a long time; its mucous membrane possesses considerable absorbent powers, and may be used for introducing nutriment and medicine.—The common peristaltic movements of the intestinal canal depend upon the contractility of the muscular coat called into action by the stimulus of the contents, and are not dependent upon cerebro-spinal nervous influence, though they may be modified through the spinal and sympathetic systems. In the duodenum and beginning of

the jejunum are small branching clusters of follicles, the glands of Brunner. The follicles of Lieberkühn are simple open glandulæ, straight narrow cæca, very abundantly distributed through the entire length of the intestinal tube. The product of these two sets of glandular follicles is the intestinal juice, a colorless, viscid, alkaline secretion, which rapidly converts hydrated starch into sugar, and probably also effects other important changes in the digestive process. When the extent of these glandular structures of the intestine is considered, the beneficial action of purgative medicines, in hastening the removal of various morbid matters from the system by direct stimulation, may be easily understood.

INVERNESS (formerly Inverness), a borough and seaport of Scotland, capital of Inverness-shire, situated on both sides of the river Ness,

a mile from its estuary and 9 m. above the junction of the latter with the Moray frith, at the N. entrance of the Caledonian canal, and 115 m. N. N. W. of Edinburgh; pop. in 1871, 14,463. The principal part of the town is on the right bank of the river, and the two sides were formerly connected by a stone bridge, built in 1685, carried away by a flood in 1849, and replaced by an iron suspension bridge. The town has five principal streets, with houses generally well built of stone, and many fine churches, banks, hotels, and public buildings. It has a coasting and foreign trade through the Moray frith and Caledonian canal, and exports grain, potatoes, wool, woollen cloth, ropes, sail cloth, leather, ale, whiskey, and dairy produce. The imports in 1871 were valued at £27,714,012 (from the United States, £3,026,867), the exports at £6,339,701 (to the

Inverness.

United States £359,348).—Inverness is a town of great antiquity. On an eminence S. E. of the town anciently stood a castle, in which it is supposed that Duncan was murdered by Macbeth. The castle was destroyed by Malcolm Canmore, who erected a new one, which was for several centuries used as a royal fortress, within whose walls a parliament was held during the reign of James I. On the site of this castle, which was blown up in 1746 by the troops of Prince Charles Stuart, stand now the court house and the county buildings. Cromwell erected a fort on the N. side of the town near the mouth of the Ness, which was demolished at the restoration, but part of the rampart still remains. Culloden moor is 3 m. from the town.

INVERNESS, a county of Nova Scotia, Canada, occupying the W. portion of Cape Breton; area, 1,221 sq. m.; pop. in 1871, 23,415, of

whom 18,197 were of Scotch, 2,682 of French, 1,307 of Irish, and 1,030 of English descent. It is well watered, and contains excellent farming land. Coal and petroleum are found. The inhabitants are chiefly engaged in agriculture and fishing. Capital, Port Hood.

INVERNESS-SHIRE, a county of Scotland, stretching diagonally across the mainland from sea to sea, between lat. 56° 40' and 57° 40' N., and including on the west the island of Skye, several smaller islands, and most of the Outer Hebrides; area, 4,255 sq. m.; pop. in 1871, 87,480. The S. W. shores are deeply indented by arms of the sea, and on the N. E. is Moray frith. The country is mountainous, well wooded, and generally fertile; about 112,000 acres are under cultivation. The Monadhia (gray mountain), or Monagh Lea, and the Benalder mountains are the principal ranges, each with an altitude of 3,000 ft. Ben Nevis, the lof-

tiest peak in Britain, rises to a height of 4,406 ft.; Cairngorm is 4,090 ft. high; and Tomnahurich, an isolated hill near Inverness, 1,984 ft. Veins of lead and silver and small quantities of iron ore have been discovered, but no coal. The chief rivers are the Spey, Ness, Beaully, and Garry, all of which have valuable salmon fisheries. Lakes occupy 132 sq. m. of the area. The largest is Loch Ness, so deep that it never freezes; with its continuations and connections, it bisects the county from N. E. to S. W. Many of these lakes are surrounded by picturesque scenery. The Gaelic language, excepting in the town of Inverness, is more prevalent than English. Agriculture is prosperous; oats are the main crop. But tillage is secondary to the raising of cattle and sheep, the former generally of the Skye or Kyle breed, and the latter Cheviot or Linton.

INVERTEBRATA, a negative term in zoölogy, employed by Lamarck to designate animals destitute of a vertebral column or backbone. Exclusive of the protozoa, these constitute three out of the four great divisions of the animal kingdom, viz., articulates, mollusks, and radiates; the remaining division consists of the vertebrates, or those having an internal skeleton with a backbone for its central support, including man and other mammals, birds, reptiles, amphibians, and fishes. The articulates, characterized by a jointed body, include insects, arachnids, centipedes, crustaceans (as crabs and lobsters), and worms; the mollusks are those generally denominated shell-bearing animals; the radiates include the echinoderms (or sea urchins, star fishes, and holothurians), the aculephs or jelly fishes, and the polyps (like *hydra*, *actinia*, and the coral animals). There is no homology or affinity between the structural type of the vertebrates and invertebrates, though there may be analogy; for instance, the head of an insect is not homologous with the head of a man, a bird, a reptile, or a fish, as it has no distinct brain cavity nor cranial vertebræ, yet its sense organs and other parts perform the same functions. Aristotle distinguished invertebrates from vertebrates, calling the former *ἀνάλμα* (bloodless) and the latter *ἐνάλμα* (having blood); Oken made the same distinction in his gut animals and flesh animals, and Ehrenberg in his *ganglioneura* and *myeloneura*; even Lamarck was aware that in his *invertibrata* all the organs are contained in a single cavity, while in the *vertebrata* there are distinct cavities for the nervous system and the organs of vegetative life. Lamarck divided the *invertibrata* into two orders and twelve classes, viz.: apathetic animals, with the five classes of *infusoria*, *polypi*, *radiaria*, *tunicata*, and *vermes*; and sensitive animals, with the seven classes of insects, arachnids, *crustacea*, annelids, cirripeds, *conchifera*, and mollusks; all distinguished from *vertebrata*, or intelligent animals. The development of the embryo and the methods of reproduction in the invertebrates are different from those of the verte-

brates. In the radiates the germ surrounds the yolk like a crust, from which the more animated parts are derived, the alimentary canal being formed from the central mass; reproduction may also take place by buds or by transverse division in the polyps and jelly fishes, the latter also presenting the curious phenomena of alternate generation. In articulates the embryo is formed at the lower part of the yolk, with its dorsal surface toward the latter, so that the yolk is enveloped from below upward, the uniting suture being upon the back. In mollusks the yolk is introduced from the lower side of the animal, as in vertebrates, but there is no upper cavity for the nervous system, as in the latter. It is thus evident that the term *invertibrata* is not equivalent in zoölogical precision to, and is far more comprehensive than, the vertebrate division; the oyster, the butterfly, the star fish, all invertebrates, have nothing in common but the absence of a vertebral column. Invertebrates include by far the most numerous and diversified forms in the animal kingdom; in them we find many important physiological questions answered, and by them we understand otherwise inexplicable problems of animal life and of its relations to changes in the earth's surface; in them we see a circulation of blood without a heart or without distinct vessels, respiration effected by a vascular integument, the nervous system reduced to its essential elements of ganglia with connecting cords, the external skeleton enclosing the muscles and organs, the plant-like mode of reproduction and of true hermaphroditism, and the multiplication of organs independently performing the same functions (as digestive sacs, gills, locomotive appendages, &c.). The different classes will be described more fully in their respective order. The whole subject is most learnedly treated by Prof. Owen in his "Lectures on the Invertebrate Animals" (1843).

INVESTITURE, the public delivery of a feud or fief by a lord to his vassal. Blackstone says: "Investitures, in their original rise, were probably intended to demonstrate, in conquered countries, the actual possession of the lord, and that he did not grant a bare litigious right, but a peaceable and firm possession. At a time when writing was seldom practised, a mere oral gift, at a distance from the spot that was given, was not likely to be long or accurately retained in the memory of bystanders who were very little interested in the grant." Investiture was performed by the presentation to the person invested of some symbol of authority and possession. Thus, when lands were transferred, it was customary for the grantor to give the grantee a turf as bearing resemblance to the property transferred.—In ecclesiastical history, by the right of investiture was meant that claimed by the temporal lord of presenting a prelate with the ring and crosier, the acknowledged emblems of episcopal and abbatial jurisdiction. Before the in-

vasion of the barbarians the election of bishops depended on the voice of the clergy and people and the suffrage of the provincial prelates. In feudal times the tenure of church property was likened to that of lay fiefs; bishops and abbots, like barons and knights, had to swear fealty and do homage to their lord paramount. The sovereign, to prevent the temporalities of an episcopal see or of an abbey from falling into the hands of his enemies, reserved to himself the right of nomination, as well as that of confirmation by investiture. These claims were resisted by churchmen as encroachments on their privileges. The general councils of Nice in 787 and of Constantinople in 869 condemned the nomination of bishops by lay authority. This condemnation was renewed in 1076 and 1080 by Gregory VII., and by Victor III. in 1087 at the council of Benevento, the latter placing under the ban of excommunication both the laymen who exercised the right of investiture and the clerics who submitted to it. But in spite of the decisions of popes and councils, the practice of investiture was continued by sovereigns. It was introduced into France and Germany by Charlemagne. The emperor Henry III. repeatedly enforced the right; and its exercise by the emperor Henry IV. was a chief ground of his quarrel with Gregory VII. The contest on this question between the popes and the emperors continued into the succeeding century, when, by a concordat agreed upon at Worms between Calixtus II. and the emperor Henry V., the latter renounced for ever his claim to invest bishops with the ring and crosier. The French kings, however, long continued to exercise a similar power, and the contests between them and the popes on the subject at length resulted in a compromise by which the monarch relinquished the presentation of the symbols, but retained the right to confer investiture by a written instrument. In England the controversy ended in a similar compromise between Paschal II. and Henry I.

INYO, a S. E. county of California, bounded E. by Nevada and W. by the Sierra Nevada mountains; area, 4,680 sq. m.; pop. in 1870, 1,956, of whom 29 were Chinese. The Sierra Nevada here embraces several lofty peaks, among which is Mt. Whitney. The Inyo, Telescope, and Amargosa mountains are parallel ranges E. of Owen's river, which flows from the north into Owen's lake, a body of water 18 by 12 m. in extent. The valley of the river is from 15 to 25 m. wide, but only a strip 2 to 3 m. broad can be cultivated. This strip, embracing about 250,000 acres, is very fertile. Argentiferous galena, gold, copper, sulphur, and tin are found. The chief productions in 1870 were 13,629 bushels of wheat, 22,915 of Indian corn, 2,175 of oats, 4,905 of barley, 6,336 of potatoes, 20,940 lbs. of butter, and 1,456 tons of hay. There were 1,514 horses, 5,662 cattle, 521 sheep, and 688 swine; 2 saw mills, and 12 quartz mills. Capital, Independence.

IO, in Greek mythology, the daughter of Inachus, the founder of the worship of Juno at Argos, or according to others of Piren or Jasus. She was beloved by Jupiter, who on account of Juno's jealousy changed her into a white heifer. Juno obtained from him the gift of the heifer, which she placed under the charge of Argus Panoptes in her grove at Mycenæ. Mercury, commissioned by Jupiter, was guided by a bird to Argus, slew him with a stone, and delivered Io. Thereupon Juno sent a gadfly, which tormented Io and pursued her in a state of frenzy over the whole earth, till at last she rested on the banks of the Nile, where she recovered the human form, bore a son to Jupiter named Epaphus, and, according to some accounts, introduced the worship of Isis, with whom she afterward became identified. The fullest narrative of her wanderings is in the "Prometheus" of Æschylus. As usually explained, Io represents the moon, and her wanderings the moon's phases; Argus, the stars of heaven; and Mercury, as the god of mists and clouds, is the Argus-slayer.

IODINE (Gr. *ἰώδης*, violet-colored), an elementary substance named from the color of its vapor, existing in various marine plants, the water of many mineral springs and of the ocean, the bittern of salt works, sponges, corals, and some rocks and minerals. It was discovered in manufacturing saltpetre by Courtois of Paris in 1812, and afterward examined and described by several chemists, but more particularly by Gay-Lussac (*Annales de chimie*, vols. lxxxviii., xc., and xci). It is represented by the symbol I; its chemical equivalent is 127. In its preparation it crystallizes either from solution or by sublimation in scales like those of micaceous iron, and in regular crystals of elongated octahedrons with rhomboidal base. These are brittle, opaque, bluish black, and of metallic lustre; their specific gravity is 4.95; they fuse at 225° F. into a dark liquid, and boil at 347°, giving off deep purple and violet vapors. Iodine is also volatile at common temperatures, and when exposed to the air diffuses an odor like that of chlorine, the vapor irritating the nostrils and exciting cough. This is among the heaviest of æriform bodies, its density being 8.7 times that of air. Alcohol, ether, and carbon disulphide dissolve iodine freely; pure water takes up only about $\frac{1}{7000}$ of its weight of it, and thus acquires a yellowish or brown tinge. By adding nitrate or chloride of ammonium, common salt, or any of the iodides, to the water, its power of dissolving iodine is greatly increased, and the solution then takes a very deep brown color. Iodine gives a yellow stain to the skin, which soon disappears. Though resembling chlorine in its combinations and some of its qualities, it has not the property of bleaching, and its chemical affinities are weaker. Its remarkable property of imparting a deep blue color to a mass or solution of starch serves as a distinguishing test of extreme delicacy. The starch solution, if cold, will sensibly indicate the pres-

ence of iodine in solutions containing only $\frac{1}{7,000,000}$ of it. It is supposed that the iodine is merely mixed in a finely divided state with the starch. It must be free for the test to succeed; and to insure this, where the iodine may be in the state of an iodide, it is recommended to add to the solution a drop of sulphuric acid, and then a little vapor of chlorine, or instead of the chlorine a drop or two of nitric acid may be used.—Though iodine is detected in a multitude of organic bodies, principally those connected with the sea or in plants growing near the salt water, it is found in largest proportion in the *fuci* or common seaweeds, and other marine plants which grow at great depths. The *fucus palmatus* and *saccharinus* are especially rich in it. The preparation of the iodine of commerce is principally carried on at Glasgow, Scotland, at Donegal, Ireland, and at Cherbourg, France, to which places are brought the half vitrified ashes produced by burning the seaweeds collected on the coast. These ashes, called kelp, or on the continent *varee*, being coarsely powdered, are digested some hours in water, and the solution is then drawn off upon a fresh portion, and from this upon a third, fourth, fifth, and it may be a sixth, until the liquor has attained a density of 1.257. The various soluble salts, including the iodides and bromides of all the alkalies, are thus taken up and separated from the earthy salts. The solution is then drawn off into broad evaporating pans, and concentrated to 60° Twaddell, or sp. gr. 1.30. At this point the sulphate of soda and chloride of sodium begin to crystallize; they are ladled out as they separate from the solution, and placed so that the drainings from them run back into the pans. When they cease to appear, the liquor is left to repose and to deposit more chloride in the pans. It is then drawn off into coolers, and left for five days for the sulphates to crystallize, as also chloride of potassium. The liquor is then again evaporated in the pans, and at 68° T., or sp. gr. 1.34, deposits carbonate of soda, and more chloride of sodium and sulphate of soda. It is again run into a cooler to cause a further separation of chloride of potassium. The process is sometimes again repeated, and the liquor brought by evaporation to 74° T. After removing all the crystals that appear, there frequently remain in the solution some chlorides, hyposulphite of soda, and sulphide of sodium. Strong sulphuric acid in the proportion of one seventh of the whole is then added, and after agitation the mixture is left to stand for two days. The sulphurous compounds are in this time decomposed, and sulphates are produced with liberation of sulphur in a free state, in sulphuretted hydrogen, and in sulphurous acid. The iodine is fixed by its combination with sodium, and, unless too much acid has been added, cannot be liberated except by oxygen. The lye is now poured into an iron still lined with lead, and when heated in a sand bath to 140°, a quantity of manganese dioxide is introduced, and the still is luted

and connected with its condensers. Iodine vapors come off at a temperature below the boiling point, and condense in the receivers. Particular care is required that the temperature does not exceed 212°, in which case the iodine is apt to combine with chlorine with loss. Cyanide of iodine often collects in white, prismatic crystals in the receiver furthest from the retort. A portion of iodine remains in the retort in combination with lead and sodium, which is recovered by first converting it into an iodide of copper by the addition of sulphate of copper, and, when this is separated by filtration, decomposing it by sulphuric acid and oxide of manganese, and collecting the vapor. The process above given is somewhat modified at different localities. A method has been proposed by Dr. Kemp to dispense with the burning of the plants, by which much iodine is volatilized and lost, and to crush the roots in which the largest proportion of iodine is concentrated, and set them to ferment; after which the iodine with other salts may be dissolved out by water acidulated with hydrochloric acid, and finally separated by proper reagents. It is also proposed to distil the seaweeds instead of incinerating them. Large quantities of iodine are now recovered from the nitrate of soda of Chili, according to a method invented by Thiercelin. The mother liquors resulting from the manufacture of saltpetre are treated with a mixture of sulphurous acid and sulphite of soda, and the iodine is precipitated as a black powder. This is placed in earthen jars, on the bottom of which are layers of quartz sand, fine at the top and coarse at the bottom; from these jars the iodine is removed by earthen spoons lined with gypsum, and the greater part of the water is thus separated. It is further purified by sublimation, but is often sold before undergoing the last named process. The amount of iodine thus reclaimed from Chili saltpetre in 1870 amounted to 30,000 lbs.—Iodine is useful as a test for starch, and also as an ingredient of various chemical reagents. Some of these are of great importance in the photographic art. From the iodide of potassium is prepared the iodide of silver, which constitutes the sensitive film upon the plates.—Iodine forms two important acids, iodic acid, HIO_3 , and periodic, HIO_4 . Hydriodic acid closely resembles hydrochloric acid, as the oxygen acids correspond respectively to chloric and perchloric acids.—Iodine has been employed in medicine since 1819, although burnt sponge, which depends upon iodine for its efficacy, had been previously used with advantage in treatment of goitre. A large number of preparations are employed both for external and internal application; the most important are solutions of iodine in alcohol, iodine dissolved in water by the aid of iodide of potassium, iodoform, the iodide of potassium, and iodides formed with mercury, iron, sulphur, sodium, and arsenic. Iodoform is a yellow salt in hexagonal flat crystals, which contains more than 96 per

cent. of iodine. Iodine and many of its compounds are absorbed with considerable rapidity from the stomach, and reappear in the excretions, especially the urine, in a short time. It has also been found in the saliva and milk; this is particularly true of the iodide of potassium. It remains but a short time in the system. Iodine itself is an irritant, and is used to produce counter-irritation. If taken in considerable quantities internally, it becomes a poison by exciting inflammation of the stomach, œsophagus, and fauces. When it is used in small doses long continued, a condition called iodism may arise, consisting in fever, restlessness, disturbed sleep, gastro-intestinal irritation, and progressive emaciation. These symptoms are not likely to arise either from the iodide of potassium or from the iodide of sodium, and are indeed not very frequent from the cautious use of iodine itself. The action of iodide of potassium in considerable quantity is sometimes marked by coryza, and a rash, like acne, upon the face and chest. Iodine has been principally used in diseases involving glandular enlargement, such as goitre and scrofula, and also with great benefit in syphilis and in chronic rheumatism. In chronic poisoning by mercury or by lead, the metal remaining in the system may be rendered more soluble, and removed by the iodide of potassium. This is shown not only by the improvement of the patient's condition, but by the detection of the metal by chemical tests in the urine. For these purposes it should be used in large doses of from 10 to 20 or 30 grains three times a day. Iodine, iodide of potassium, and iodides of sulphur, lead, and mercury are used externally in the shape of tincture and ointment. Some of these are useful counter-irritants. Any specific absorbent effect on the part of the ointment is not clearly proved. Injections of tincture of iodine have been made into diseased cavities, especially those lined with serous or synovial membrane, as the joints, tunica vaginalis, and ovarian cysts, to excite adhesive inflammation; and it has been injected into the pleura, and even the pericardium and peritoneum. Inhalations of the vapor have been employed in pulmonary disease. Iodic alimentation, by introducing iodine into articles of food, as bread, has been proposed. Iodine has also been united with cod-liver oil. A solution of iodine in iodide of potassium is useful in the detection of many alkaloids, with

which it forms more or less insoluble compounds. It has also been proposed as an antidote to alkaloid poisons; but it should be borne in mind that the compounds formed by iodine with strychnia, for instance, are probably only relatively harmless, and the absorption merely delayed, so that other means of treatment should not be neglected, although the iodine solution, if convenient, may be used to gain time. The special forms of disease in which iodine and its preparations have been found most useful are goitre, enlarged scrofulous glands, scrofulous ulcers and abscesses, secondary and tertiary syphilis, enlargement and induration of the ovaries, chronic affections of the os uteri, dysmenorrhœa, enlargement of the spleen, chronic rheumatism and gout, pleurisy with effusion, and tubercular affections of the head and chest. The dose of iodine for internal use is from $\frac{1}{10}$ to $\frac{1}{2}$ gr. three times a day; of iodide of potassium, from 1 gr. to 12 or 15 grs.; of iodide of sodium, 5 to 20 grs.; of iodide of iron, 3 or 4 grs.; of iodide of mercury, $\frac{1}{4}$ gr. to 1 gr.; of biniodide of mercury, $\frac{1}{10}$ to $\frac{1}{8}$ gr.; of iodide of sulphur, 2 or 3 grs.; of iodoform, $\frac{1}{4}$ gr. to 2 grs. Iodine and the iodides are best given before or after eating; they are apt to irritate an empty stomach. A generous diet is usually advisable in connection with a therapeutic course of iodine or of the iodides.

IONA, or **Icolmkill**, called also **I** or **Hy**, a small island of the inner Hebrides, situated in lat. $56^{\circ} 22' N.$, lon. $6^{\circ} 25' W.$, 9 m. S. W. of Staffa, and separated from the island of Mull by a channel $1\frac{1}{2}$ m. wide, called the sound of I or

Ruins of St. Mary's Church

of Icolmkill. It is embraced within the parish of Kilfinichen and county of Argyre, and is 3 m. long by $1\frac{1}{2}$ m. broad; pop. about 300. It has an irregular surface of moorland, rising in places to 400 ft. About 600 acres of the island are under cultivation, producing barley

and potatoes, but the chief occupation of the inhabitants is rearing black cattle and fishing. There is a small village, containing two churches, 40 or 50 detached cottages, and a school.—The island was given by the Pictish king Bridius in 563 to St. Columba (hence the name Icolmkill, the island of Columba of the cell), who founded there a celebrated monastery. Previous to his time the island was the chief seat of the rites of druidism. He established a college, which acquired great wealth and increased in influence till the time of the reformation. The Culdees controlled it until the beginning of the 13th century, when they were driven out by those who acknowledged the authority of Rome. A nunnery established on the island about this time continued till 1543, when Anna Macdonald, the last prioress, died. The religious establishment was altogether broken up by the act of the Scotch parliament (1560) abolishing all religious houses. The island then passed into the hands of the McLeans, but is now the property of the duke of Argyll.—Iona is said to have had at one time 360 stone crosses, resembling those of Ireland, but most of them were destroyed by Puritan zeal, and only four now remain. Sepulchral remains cover the island, both in the shape of cairns and of stone monuments of all kinds, Iona having been considered from time immemorial a sacred island. An old prophecy declared that seven years before the end of the world a second deluge would drown all nations, but that St. Columba's isle would swim above the flood; and this tradition made it the chosen cemetery of kings. Numbers of Scotch, Irish, Norwegian, and even French kings were buried there, the last of whom is said to have been the famous Macbeth. Among the principal ruins are the church of St. Mary, a cruciform building with a square tower about 75 ft. high, dating from the beginning of the 13th century; St. Mary's nunnery, built in the 12th; and St. Oran's chapel, probably in the 11th.

IONIA, in ancient geography, a country on the W. coast of Asia Minor, lying mainly between the river Hermus on the north and the Mæander on the south, and including the islands of Chios and Samos. This district was named after the Ionians, who returned from Attica to these shores, from which they had previously emigrated to European Greece, and founded here the 12 cities, Miletus, Myus, Priene, Ephesus, Lebedus, Colophon, Teos, Erythræ, Clazomenæ, Phocæa, Chios, and Samos, which were designated as the Ionian Dodecapolis. (See **IONIANS**.) The new colonists settled among kindred Greek tribes engaged in fishing and navigation, and the Lydians seem to have allowed their settlements on the coast without regarding them as an encroachment. The Ionians demanded rights of supremacy and the best localities for the foundation of cities for themselves, and drove the old inhabitants out of their seats. The legends speak of their struggles with the Carians and Leleges. The

religious and political centre of the Dodecapolis was the Panionium, which was a temple of Neptune, on the N. slope of Mount Mycale, near Priene, where the common affairs of the independent republics were discussed at regular meetings. About 700 B. C. Smyrna, which until then had belonged to Æolis, became by treachery a member of the Ionian confederacy, which subsequently consisted of 13 cities. The country soon attained great prosperity. Before the middle of the 6th century, however, the Ionian cities became subject to Lydia, and on the fall of Cræsus they were annexed to the Persian empire by Cyrus. In 501 and 494 the Ionians made unsuccessful efforts to regain their independence, and they assisted the Greeks against the Persians at the battle of Mycale (479). The Persian yoke was at length shaken off by the victory at the Eurymedon, but the peace of Antalcidas (387) renewed it. On the overthrow of the Persian empire by Alexander, Ionia became subject to Macedon, subsequently to the Syrian and Pergamene kingdoms; and in 133 it fell into the hands of the Romans by the bequest of Attalus III. of Pergamus. The Ionian cities soon lost their importance, and under the Turkish supremacy all but Smyrna disappeared or sank into total insignificance. Though Ionia never possessed great political power, the commerce of its cities extended to the shores of the Black sea and the sea of Azov, as well as to the coasts of the Mediterranean. Ionia was the cradle of Greek epic and elegiac poetry, history, philosophy, medicine, and other sciences; it developed a new style of architecture, and it was the birthplace of several celebrated painters.

IONIA, a S. county of the southern peninsula of Michigan, drained by Grand river; area, 576 sq. m.; pop. in 1870, 27,681. It has an undulating surface, about half of which is densely wooded. Red sandstone is quarried. The soil is rich, and much of it alluvial. The Detroit and Milwaukee, and the Detroit, Lansing, and Lake Michigan railroads pass through it. The chief productions in 1870 were 665,521 bushels of wheat, 366,811 of Indian corn, 284,314 of oats, 316,487 of potatoes, 32,825 lbs. of hops, 120,870 of maple sugar, 317,261 of wool, 656,369 of butter, and 34,271 tons of hay. There were 6,514 horses, 7,424 milch cows, 1,844 working oxen, 8,093 other cattle, 78,541 sheep, and 10,686 swine; 12 manufactories of agricultural implements, 10 of carriages, 6 of cabinet furniture, 10 of iron castings, 8 of saddlery and harness, 9 of sash, doors, and blinds, 3 of woollen goods, 2 planing mills, 19 saw mills, and 9 flour mills. Capital, Ionia.

IONIAN ISLANDS, the collective name of seven islands belonging to Greece, six of which are in the Ionian sea (a name applied from ancient times to the part of the Mediterranean between the W. coast of Greece and the E. coast of Italy and Sicily), viz.: Corfu, Santa Maura, Ithaca or Thiaki, Cephalonia, Zante, Paxo, and Cerigo, with some smaller dependencies,

between lat. 35° 48' and 40° 30' N., and lon. 19° and 23° 18' E.; aggregate area, 1,113 sq. m.; pop. in 1870, 229,516. The islands are very mountainous, and mostly rise with rugged abruptness from the sea, but have fine havens on their coasts. Mt. Ænos in Cephalonia is 5,246 ft. high, and in the other islands there are elevations ranging from 1,000 to 3,800 ft. The geological formation is chiefly limestone, mixed with sandstone and gypsum. There are no active volcanoes. Most of the islands abound in fine natural scenery, and here and there bear luxuriant vegetation. The soil is generally dry and calcareous, and about half the surface is arable. The climate is variable, but healthy. The spring is mild, the summer hot and dry, the autumn rainy, and the winter tempestuous. The sirocco is often felt, and N. winds blow violently during winter. Snow falls often, but does not last long except on the mountains. Earthquakes are not uncommon. Iron, coal, manganese, sulphate of soda, marl, clay, chalcedony, quartz, and gray marble are the most important minerals. The principal vegetable products are the olive, lemon, orange, and fig, grapes, currants, wheat, maize, barley, oats, flax, pulse, and cotton. The last is of very good quality. The celebrated currants of Zante are the fruit of a dwarf vine. The valonia oak (*quercus agilops*) is valued for its acorns, besides being a beautiful tree. Madder grows wild, and the *cactus Opuntia*, which furnishes the food of the cochineal insect, thrives in all the islands, but is little attended to. Experiments in the culture of indigo have succeeded. Farms are mostly small, and are generally let annually on shares. Sheep and goats are the only animals reared in considerable numbers. The manufactures of these islands consist almost entirely of coarse cloths, earthenware, soap, salt, some silk and cotton fabrics, and filigree work. Although the coasts abound with fish, the fisheries are not prosecuted systematically. A large coasting trade is carried on. The imports are sugar, coffee, drugs, raw and manufactured cotton and silk, wool and woollen cloth, glass, hardware, staves and hoops, iron, timber, wheat, Indian corn, rice, flour, cheese, salted fish, cattle, sheep, drugs, and tobacco; the exports are currants and olive oil, also wine, brandy, liqueurs, honey, wax, valonia acorns, soap, salt, and hare and lamb skins.—The natives are Greeks, with a considerable admixture of Albanian and Italian blood. Italian is understood in most of the large towns, and is generally spoken by the higher classes. Some thousands of the islanders cross annually to the mainland to assist in the labors of harvest, for which they receive payment in grain. Education flourishes, and each of the islands has an academy supported by the government, at which ancient Greek, Latin, modern languages, and mathematics are taught. A university was founded at Corfu in 1823. Four fifths of the population belong to the Greek church, under the archbishops of Corfu, Zante,

Cephalonia, Santa Maura, and Cerigo. The Roman Catholics have an archbishop of Corfu and a bishop of Zante and Cephalonia. There are several thousand Jews, living chiefly in Corfu, and enjoying rights of citizenship.—In Grecian history these islands figured singly as Coreyra, Leucas, Ithaca, Cephallenia, Zacynthus, Paxos, and Cythera. In the 12th century they were taken by the kings of Sicily, and in the 14th fell under the jurisdiction of the Venetians, and so remained till the fall of Venice threw them into the hands of the French by the treaty of Campo Formio (1797). Russia and Turkey jointly expelled the French, and in 1800 erected these islands into the Septinsular republic, which, under the protection of Turkey, failed as an experiment of self-government. By a secret article in the treaty of Tilsit in 1807 they were given to the French; but being occupied by the British during the wars from 1809 to 1814, they were secured to that power by the treaty of Paris in November, 1815. From 1814 to 1863 the islands were a republican confederation, under the protectorate of Great Britain, and were called the United States of the Ionian Islands. The government was vested in a lord high commissioner appointed by the British crown, and a parliament consisting of a senate and legislative assembly. Attempts at insurrection in 1848 and 1849 were suppressed with rigor. In 1863-'4 they were incorporated with the kingdom of Greece, when Cerigo was united as an eparchy with the nomarchy of Argolis and Corinth, and the remaining islands were formed into three nomarchies, Coreyra (Corfu), Cephalonia, and Zante (Zacynthus). (See GREECE.)

IONIANS, or **Iaones** (Gr. *Ἴωνες* and *Ἰάονες*), an ancient maritime race of Greek descent, having their chief seat in western Asia Minor and the adjacent islands. The name was extended to cover countries further west as Greece and the Greeks became better known, appearing in various dialectic forms, as Javan (*Yavan*) with the Hebrews, Yuna or Yauna with the Persians, Unim with the Egyptians, and the Yavanas or Yonas in India. E. Curtius conjectures that after the Ionians had learned navigation and become masters of their own sea, they sailed in the track of the Phœnicians, and settled beside them in all parts of the eastern Mediterranean. The monuments of Egypt show as early as the 18th dynasty the same group of hieroglyphs by which the Greeks were designated at the time of the Ptolemies, and it is believed that the Unim first known to the Egyptians were the Ionian Greeks. If this is correct, the Ionians were settled already about 1500 B. C. in the delta of the Nile. Cyprus is called Yavnan, the island of the Ionians (*νησος Ἰαόνων*), when it first became known to the Assyrians in the reign of Sargon; but in some of Sargon's inscriptions it is corrupted into Yatan. The Mosaic table of nations mentions the children of Javan, among whom are included the Kittim of Cyprus; but the name Javan,

as is expressly stated, covers a multitude of islands. The prophet Joel curses the towns of Tyre and Sidon for selling the children of Judah and Jerusalem to the children of Javan, and removing them far away among the gentiles. It is therefore supposed that the Hebrews were acquainted with the Ionians as early as 1000 B. C. It is noticeable that the term *Ἴάονες* only once occurs in the Iliad, and that in one of its later parts. The legendary accounts of the Greeks say that about the middle of the 11th century B. C. the Ionians emigrated from Attica and settled on the shores of Asia Minor, expelling and exterminating some of the inhabitants, while others were allowed to amalgamate with them. Other myths speak of nations from the east settling in European Greece. Notwithstanding the pride taken by the Greeks in their autochthony, they constantly connect the foundation of their social life with the arrival of highly gifted strangers, whose supernatural power and wisdom were believed to have brought a new order into their life. E. Curtius says: "Two different points of view are, however, undeniably maintained throughout these myths: in the first place, the notion of the foreign element, . . . and secondly, the notion of common relationship." "In what other way can these two undeniably dominant ideas be explained and harmonized, except by assuming that the colonists in question were also Hellenes; that they came from the east indeed, but from a Greek east, where, with the receptivity of mind characteristic of the Ionian race, they had domesticated among themselves, and given a Hellenic transformation to, the civilization of the East, in order to hand it over in this state to the brethren of their own race? But since these Ionic Greeks, for so we may shortly designate them as a body of population, had not only settled in their own home, but also among the Phœnicians, in lands colonized by the latter, in Lycia and in Caria, and in the delta of the Nile, the settlers coming from the other side, the heroes and founders of towns in question, easily came to be called Phœnicians and Egyptians. For it is inconceivable that Canaanites proper . . . ever founded principalities among a Hellenic population." Thus at the beginning of history Curtius finds traces of the Ionians on the shores of the sea of Thessaly, and of the sea of Eubœa, called Hellopia, after a son of Ion; in southern Bœotia, especially on the Asopus and the declivities of the Helicon; in the whole of Attica; further in a long connected line on either shore of the Saronic and Corinthian seas; in Argolis, and on all the coasts of the Peloponnesus; and in the mountainous country of the interior. The movement of the Ionians from Attica to the W. coast of Asia Minor was accordingly a remigration to the original settlements. It was the natural result of the overpeopling of southern Greece, occasioned by the violent advance of the northern highlanders or the continental tribes of the Hellenic nation. In the

midst of these movements, which had revolutionized all the states from Olympus to Cape Malea, Attica alone had remained tranquil; but it now became the refuge of the multitudes driven out of the other districts, and the narrow and poor little land was overflowing with inhabitants, so that relief became necessary. All the Greeks belonging to the old Ionic race, suffering under this great pressure, therefore started, and having preserved an inner connection notwithstanding their dispersion, they reassembled in the middle coast tracts of Asia Minor, and this land around the mouths of the four rivers became the new Ionia, into which were transplanted the political institutions, priesthoods, and festive rituals of Attica. (See IONIA.)—The Yavanas in ancient Sanskrit literature are supposed to have been Ionians, who made inroads into India through the northwest, probably through Cashmere, coming from the Euphrates, and penetrating as far as Orissa. The term Yavana was applied also to Greeks left by Alexander to garrison the banks of the Indus. Though Sir William Jones interprets the word as designating Ionians or Asiatic Greeks, yet the chief argument in favor of it is the difficulty of attaching it to any other people. Yavana does not seem to be exclusively applied to the Greeks. According to Caldwell, it had originally that signification, and was subsequently applied to any race approaching India from the west. According to Lassen, it was used to designate only the Semitic nations. The modern Hindoos of northern India apply the term Yavana to Mohammedans of every description, but it is certain that in works prior to the Mohammedan era some other people must be intended. Bunsen supposes that it may be an ancient inaccurate name of a people who pushed on toward the Mediterranean. In the present state of these researches it is impossible to retrace with certainty the occupancy of central Asia and India by the ancient Ionians.—See Ernst Curtius, *Die Ionier vor der ionischen Wanderung* (Berlin, 1855), and *Geschichte und Topographie Kleinasiens* (1872); Hunter, "Orissa" (London, 1872); and Chabas, *Les peuples connus par les Égyptiens*, in *L'Antiquité préhistorique* (Paris, 1873).

IONIES, a small tribe of Indians in the United States, belonging to the family of the Caddoes or Cadodaquios. They regard the Hot Springs of Arkansas as their original seat. They formed part of the confederation known to the Spaniards as Texas or Friends, and were first known about the time of La Salle, who passed through their country. They were long on the Red river, but about 1823 moved into Texas, finally settling on the Brazos. With the Caddoes they had suffered from disease and from the attacks of the Osages and Comanches. Their houses are a conical framework of poles, about 25 ft. in diameter and 20 ft. high, thatched with long prairie grass, with low doors. They are among the best of the

Indian tribes, cultivating enough land for their support. They were removed by government in 1859 to the "leased district" on the Washita river near old Fort Cobb, Indian territory, and in 1872 numbered only 85.

IOSCO, a N. E. county of the southern peninsula of Michigan, bordering on Lake Huron and Saginaw bay, intersected by the Au Sable, and drained by the Au Grais river; area, 575 sq. m.; pop. in 1870, 3,163. The surface is nearly level, and partly covered with pine forests. In 1870 there were 11 saw mills, producing \$646,151 worth of lumber, and 1 manufactory of ground plaster. Capital, Tawas City.

IOWA, one of the interior states of the American Union, and the 16th admitted under the federal constitution, situated between lat. 40° 20' and 43° 30' N., and lon. 90° 12' and 96° 38' W.; general extent N. and S. 208 m., and E. and W. about 300 m.; area, 55,045 sq. m. It is bounded N. by Minnesota, E. by the Mississippi, which separates it from Wisconsin

State Seal of Iowa.

and Illinois, S. by Missouri, and W. by the Missouri and Big Sioux rivers, which separate it from Nebraska and Dakota. The state is divided into 99 counties, viz.: Adair, Adams, Allamakee, Appanoose, Audubon, Benton, Black Hawk, Boone, Bremer, Buchanan, Buena Vista, Butler, Calhoun, Carroll, Cass, Cedar, Cerro Gordo, Cherokee, Chickasaw, Clarke, Clay, Clayton, Clinton, Crawford, Dallas, Davis, Decatur, Delaware, Des Moines, Dickinson, Dubuque, Emmett, Fayette, Floyd, Franklin, Fremont, Greene, Grundy, Guthrie, Hamilton, Hancock, Hardin, Harrison, Henry, Howard, Humboldt, Ida, Iowa, Jackson, Jasper, Jefferson, Johnson, Jones, Keokuk, Kossuth, Lee, Linn, Louisa, Lucas, Lyon, Madison, Mahaska, Marion, Marshall, Mills, Mitchell, Monona, Monroe, Montgomery, Muscatine, O'Brien, Osceola, Page, Palo Alto, Plymouth, Pocahontas, Polk, Pottawattamie, Poweshiek, Ringgold, Sac, Scott, Shelby, Sioux, Story, Tama, Taylor, Union, Van Buren, Wapello, Warren, Washington, Wayne, Webster, Winnebago, Winneshie, Woodbury, Worth, Wright. Des

Moines is the capital. The cities of Iowa, as reported by the census of 1870, were: Burlington, having 14,930 inhabitants; Cedar Falls, 3,070; Cedar Rapids, 5,940; Clinton, 6,129; Council Bluffs, 10,020; Davenport, 20,038; Des Moines, 12,035; Dubuque, 18,435; Fairfield, 2,226; Fort Dodge, 3,095; Fort Madison, 4,011; Glenwood, 1,291; Independence, 2,945; Iowa City, the former capital, 5,914; Keokuk, 12,766; Lyons, 4,088; McGregor, 2,074; Maquoketa, 1,756; Marshalltown, 3,218; Muscatine, 6,718; Oskaloosa, 3,204; Ottumwa, 5,214; Sioux City, 3,401; Waterloo, 4,337; Waverly, 2,291; and Winterset, 1,485. The population of Iowa (exclusive of tribal Indians, now numbering about 300, other Indians being included in the total), according to the federal census, and its rank in the Union, have been as follows:

YEARS.	White.	Colored.	Total.	Rank.
1840.....	42,924	188	43,112	28
1850.....	191,881	383	192,214	27
1860.....	673,779	1,069	674,913	20
1870.....	1,188,207	5,762	1,194,020	11

According to the state census of 1873, the population had increased to 1,251,333. There were 231,540 dwellings and 238,098 families. The number of persons entitled to vote was 261,205; of militia, 190,383; of foreigners not naturalized, 26,250. The population of Burlington was returned at 20,156; Council Bluffs, 10,525; Davenport, 20,550; Des Moines, 15,061; Dubuque, 22,151; Keokuk, 11,761. Of the total population in 1870, 625,917 were males and 568,103 females; 989,328 were of native and 204,692 of foreign birth, including 115,053 males and 89,639 females. Of the native population, 428,620 were born in the state, 65,391 in Illinois, 64,083 in Indiana, 14,186 in Kentucky, 5,943 in Maine, 5,972 in Maryland, 8,929 in Massachusetts, 8,918 in Michigan, 13,831 in Missouri, 5,057 in New Hampshire, 5,688 in New Jersey, 79,143 in New York, 5,090 in North Carolina, 126,285 in Ohio, 73,435 in Pennsylvania, 12,204 in Vermont, 19,558 in Virginia and West Virginia, and 24,309 in Wisconsin. Of the foreigners, 17,907 were born in British America, 2,827 in Denmark, 3,130 in France, 66,162 in Germany, 16,660 in England, 40,124 in Ireland, 5,248 in Scotland, 1,967 in Wales, 4,513 in Holland, 17,558 in Norway, 10,796 in Sweden, and 3,937 in Switzerland. The density of population was 21.69 to a square mile. There were 222,430 families with an average of 5.37 persons to each, and 219,846 dwellings with an average of 5.44 persons to each. The increase of population from 1860 to 1870 was 76.91 per cent. The number of male citizens 21 years old and upward was 255,802. There were 394,696 persons from 5 to 18 years of age; the total number attending school was 306,353; 24,115 persons 10 years old and upward were unable to read, and 45,671 could not write; of the latter, 24,979 were of native and 20,692 of foreign birth; 44,145

were white and 1,524 colored; 21,065 were males and 24,704 females; 5,928 were from 10 to 15 years of age, 3,826 from 15 to 21, and 35,980, 21 and over, of whom 14,782 were white males, 19,825 white females, 635 colored males, and 673 colored females; 5.3 per cent. of the male adults and 8.37 per cent. of the female adults were illiterate. The number of paupers supported during the year ending June 1, 1870, was 1,543, at a cost of \$175,179; 853 were receiving support at the end of the year, of whom 542, including 56 colored, were of native, and 311 of foreign birth. The number of persons convicted of crime during the year was 615. Of the number (397) in prison June 1, 1870, 287 were of native and 110 of foreign birth. The state contained 465 blind, 549 deaf and dumb, 742 insane, and 533 idiotic. Of the total population 10 years of age and over (837,959), there were engaged in all occupations 344,276; in agriculture, 210,263, of whom 69,821 were laborers, 139,478 farmers and planters, and 810 gardeners and nurserymen; in professional and personal services, 58,484, including 1,596 clergymen, 15,725 domestic servants, 202 journalists, 24,823 laborers not specified, 1,456 lawyers, 1,865 physicians and surgeons, 6,012 teachers not specified; in trade and transportation, 28,210; and in manufactures and mechanical and mining industries, 47,319. The number of deaths from all causes was 9,597; from consumption, 1,313, being one death from that disease to 7.3 from all causes; from pneumonia, 678, or 1 to 14.2; from whooping cough, 337, being a higher ratio of deaths from that disease than in any other state except Nebraska and Arkansas; from diphtheria and scarlet fever, 473; intermittent and remittent fevers, 161; enteric fever, 521; diarrhoea, 339; dysentery, 228; enteritis, 238.—Besides the great rivers which bound it, Iowa has a large number of interior watercourses, many navigable, and others of less dimensions, but supplying abundant water power. All the streams of the state flow into the great boundary rivers. The Mississippi receives the Des Moines, the Checaque or Skunk, the Iowa and its affluent the Red Cedar, the Wapsipinicon, the Maquoketa, the Turkey, the Upper Iowa, &c., all of which have S. E. courses, and generally run parallel with each other. The Iowa rises in Hancock co., in the northern part of the state, and empties into the Mississippi 35 m. above Burlington; its length is about 300 m., and it is navigable to Iowa City, 80 m. The rivers flowing to the Missouri are short, and as to volume scarcely compare with the smallest class flowing to the Mississippi. The Big Sioux forms a portion of the W. boundary. The Chariton, Grand, Platte, Nodaway, and Nishnabotona rise in the south of Iowa, pass into Missouri, and join the Missouri river in its course through that state. The largest interior river of the state is the Des Moines, which flows from N. W. to S. E. not less than 300 m. through Iowa, and drains more

than 10,000 sq. m. of its territory. It forms a portion of the boundary line between Iowa on the N. E. and Missouri on the S. W. Next in size of the interior rivers is the Red Cedar, which rises in Minnesota, and after a S. E. course joins the Iowa in Louisa co. about 30 m. from its mouth. One of the most important streams of N. W. Iowa is Little Sioux river, which rises near the Minnesota border, and after meandering about 250 m. falls into the Missouri. In the northern portion of the state there are numerous small but beautiful lakes, which are a part of the system of lakes extending northward into Minnesota. One of the largest, Lake Okoboji, in Dickinson co., is about 15 m. long and from $\frac{1}{4}$ to 2 m. wide.—The surface of Iowa is generally undulating, and forms a country of unrivalled beauty. It has no mountains nor even high hills; yet on the margins of the rivers there are frequent bluffs of calcareous strata intersected by ravines. These bluffs are generally from 40 to 130 ft. high, and are the breastwork of table lands which sweep away from them in gentle undulations. The southern portion of the state is the most picturesque, abounding with grassy lawns and verdant plains, interspersed with groves and meandering rivulets, and intersected by the larger rivers which flow to the Mississippi or by the numerous affluents of the Missouri. In the northeastern part the surface is more elevated, hills and mounds are not uncommon, their tops covered with towering oaks, and the rivers tumble over precipitous ledges of craggy rocks. The N. E. section abounds in lead ore and various other metals, but nevertheless contains much excellent land. The unique and admirably diversified prairies of Iowa are, however, its most distinguishing feature. These natural meadows are covered with a rich coating of coarse grass, forming excellent pasturage, and are not infrequently interspersed with hazel thickets and fragrant shrubs, and in the season of flowers are decorated with a brilliant garniture of honeysuckles, jessamines, wild roses, and violets.—A geological survey of Iowa was begun under the direction of Prof. James Hall, the chemical and mineralogical department being conducted by Mr. J. D. Whitney, and a report in 2 vols. 8vo was published in 1858-'9, which presents the general arrangement of the formations, with details of their fossils and economical importance. The survey was resumed in 1866, under the direction of Dr. Charles A. White of Iowa City. The geological formations are exclusively palæozoic, their range being from the Potsdam sandstone to the coal measures, inclusive. The latter formation occupies the S. and W. portion of the state, and reaches within a few miles at its S. E. corner of the Mississippi river, from which it is separated by a belt of about 20 m., over which the carboniferous limestone is spread out. This limestone outcrop thence extends diagonally across the state to the extreme N. W. corner. Toward the northeast

lower formations continue to appear in succession, and stretch in long parallel belts N. W. and S. E. The course of the rivers, as they descend from the N. border of the state to the Mississippi, is along the range of these formations; and it is remarkable how each river keeps almost exclusively along the same geological belt for nearly 200 m. The successive belts are thus designated by Prof. Hall, advancing N. E. in the descending series from the coal measures and the underlying carboniferous limestone: the Hamilton and Chemung groups of the Devonian series, the Leclaire and Niagara limestones of the upper Silurian, the Hudson river shales, Galena limestone, Trenton limestone, St. Peter's sandstone, and Potsdam sandstone of the lower Silurian. The last occupy the N. E. corner of the state. The coal measures are regarded as the most permanent source of mineral wealth, though the lead mines in the Galena limestone have attracted the earliest and greatest attention, and have so far been the most important in the value of their productions. Their aggregate thickness in the S. part of the state is less than 500 ft., and in this are found several workable beds of bituminous coal, one of which is sometimes 7 ft. thick. The formation thins out as it spreads over the carboniferous limestone, and in this are found several outlying shallow basins of small extent. They are also met with beyond the limits of this rock, scattered in the depressions of the Devonian, and even the Silurian series, and resting unconformably upon the upturned edges of these lower formations. Along the Mississippi river, between Davenport and Muscatine, a deposit of this character stretches 20 m. up and down the river, and not more than 3 m. back from it. This is the extension on the Iowa side of the Illinois coal field, the Mississippi river having completely separated this marginal portion from the main body. The thickness of this isolated group of coal measures is not more than about 70 ft. It contains one coal bed which is identified as the lowest workable coal of the series; it is of no great importance, being only about 2½ ft. thick. A few yards beneath it is a bed of carbonaceous slate, which sometimes presents a seam of cannel coal a foot thick. The coal field of the state embraces an area of about 20,000 sq. m.; the coal is bituminous and of excellent quality. In the N. part of the state are extensive beds of superior peat from 4 ft. to 10 ft. in depth. The lead mines are in the belt occupied by the Galena limestone. This tract reaches the Mississippi river at Dubuque, and lies along the valley of Turkey river toward the N. W.; but the only mines that have been worked in it are near the Mississippi. The ore is chiefly found in vertical crevices which are traced in E. and W. lines with remarkable regularity. They are congregated in great number in the immediate vicinity of Dubuque, and from the report of the state geologists it appears that no district in the Mississippi valley has

produced so large an amount of ore for its extent as this tract of 12 or 15 sq. m. From 4,000,000 to 6,000,000 lbs. of ore have been smelted annually at the Dubuque mines, yielding about 70 per cent. of lead. The crevices in the limestone are frequently found to expand into what are called openings and large caves several hundred feet long. The walls of these are incrustated with the sulphuret of lead, of which a single cave sometimes furnishes several million pounds. The depth of the mines is limited to the thickness of the Galena limestone, which seldom reaches 200 ft. In the blue limestone, which underlies it, the crevices either close up or are unproductive. The yield of ore is very irregular, and the same mines rarely continue to be worked for even a few years. (See LEAD.) Iowa has also small deposits of iron ore, and there are many other minerals of considerable value. A deposit of gypsum of remarkable fineness and purity exists near Fort Dodge; it is confined to an area of about 6 by 3 m. on both sides of the Des Moines river, and is from 25 to 30 ft. thick. Plaster of Paris of superior quality has been manufactured from it. Building stone of the best description, various clays, &c., sufficient for all present or prospective requirements, are found.—The soils of Iowa are generally excellent, and no state of the Union has a smaller amount of inferior land. The valleys of the Red Cedar, Iowa, and Des Moines, as high as lat. 42° 30', present a body of arable land which, taken as a whole, for richness in organic elements, for amount of saline matter, and due admixture of earthy silicates, affords a combination that belongs only to the most fertile upland plains. North of this, the best agricultural region of the state, the lands are inferior, but still not unprofitable, and the lower grounds are either wet and marshy or filled with numerous ponds, and entirely destitute of timber.—The climate of Iowa is moderate, and highly favorable for agricultural operations. As a general rule the peach blossoms in mid April, and wheat ripens early in August. The winters, however, are severe from the prevalence of N. and N. W. winds, which sweep over the level prairies without obstruction; but they are very equable and healthful. In summer the winds are from the west and south, and, being constant, greatly relieve the heats of that season. The mean temperature of the year is about 48° F.; spring, 47½°; summer, 70½°; autumn, 45°; winter, 23½°. The highest temperature observed for 30 years was 99°, Aug. 31, 1854; the lowest —30°, Jan. 18, 1857. The temperature is seldom lower than —10°, or higher than 90°. The mean annual amount of rainfall for 30 years was 44.27 in.; least, 23.35 in.; greatest, 74.49 in. Iowa is classed among the most healthy countries of the world, a fact to be attributed to the excellent drainage furnished by its rolling surface. The exceptions to this condition are very rare.—The natural growths of Iowa are similar to those of the whole middle zone of the

Union. North of lat. 42° timber is comparatively scarce, but south of that line and along the rivers the country is well wooded. Ash, elm, sugar and white maple, and cottonwood grow in the river bottoms; and in other localities are found poplar, oak, hickory, walnut, basswood, &c. In the north there is some pine timber. Groves of cedar are found along the Iowa and Red Cedar rivers. Among fruit trees, the apple, cherry, and pear attain the highest perfection; the wild plum, grape, and gooseberry are indigenous. For the cultivation of the cereals no part of the country surpasses this state; it is also favorable both in climate and soil for the castor oil plant, flax, tobacco, &c. Potatoes are also a favorite staple. Tea has been raised in Crawford co., the yield being over 700 lbs. to the acre. Iowa ranks high in agriculture. According to the census of 1870, it produced more wheat and Indian corn than any other state in the Union except Illinois, and ranked fifth in the production of oats. The state contained 9,396,467 acres of improved land, 2,524,796 of woodland, and 3,620,533 of other unimproved land. The total number of farms was 116,292, of which 34,041 contained from 20 to 50 acres, 41,372 from 50 to 100, 30,142 from 100 to 500, 321 from 500 to 1,000, and 38 over 1,000. The cash value of farms was \$392,662,441; of farming implements and machinery, \$20,509,582; total amount of wages paid during the year, including value of board, \$9,377,878; total (estimated) value of all farm productions, including betterments and additions to stock, \$114,386,441; value of orchard products, \$1,075,169; of products of market gardens, \$244,963; of forest products, \$1,200,468; of home manufactures, \$521,404; of animals slaughtered or sold for slaughter, \$25,-

781,223; of all live stock, \$82,987,133. There were on farms 433,642 horses, 25,485 mules and asses, 369,800 milch cows, 614,366 other cattle, 855,493 sheep, and 1,353,908 swine. The chief productions were 28,708,312 bushels of spring and 727,380 of winter wheat, 505,807 of rye, 68,935,065 of Indian corn, 21,005,142 of oats, 1,960,779 of barley, 109,432 of buckwheat, 42,313 of peas and beans, 5,914,620 of Irish and 34,292 of sweet potatoes, 2,475 of clover seed, 53,432 of grass seed, 88,621 of flax seed, 1,777,339 tons of hay, 71,792 lbs. of tobacco, 2,967,043 of wool, 27,512,179 of butter, 1,087,741 of cheese, 146,490 of maple sugar, 171,113 of hops, 695,518 of flax, 853,213 of honey, 2,225 of wax, 37,518 gallons of wine, 638,800 of milk sold, 1,218,635 of sorghum and 9,315 of maple molasses. According to the state census, the number of acres of improved land in 1872 was 9,987,788. There were produced in that year 32,437,836 bushels of wheat, 141,744,522 of Indian corn, 22,113,013 of oats, 5,770,169 of barley, and 2,348,884 lbs. of wool. The total assessed value of live stock in 1873 was \$36,521,346. There were 1,178,017 cattle, valued at \$12,931,807; 557,052 horses, \$18,936,037; 32,010 mules, \$1,357,478; 523,089 sheep, \$572,438; and 1,460,784 swine, \$2,723,586.—The total number of manufacturing establishments was 6,566, having 899 steam engines of 25,298 horse power, and 726 water wheels of 14,249 horse power, and employing 25,032 hands, of whom 23,395 were males above 16 years of age, 951 females above 15, and 686 youths. The capital invested amounted to \$22,420,183; wages paid during the year, \$6,893,292; value of materials, \$27,682,096; products, \$46,534,322. The chief industries were as follows:

INDUSTRIES.	Number of establishments.	Steam engines, horse power.	Water wheels, horse power.	Hands employed.	Capital invested.	Wages paid.	Value of materials.	Value of products.

—Iowa has no direct foreign commerce, but its trade with the Atlantic and gulf ports and the interior is comparatively extensive. The exports consist of the products of agriculture and mines, and the imports of eastern and foreign manufactures, groceries, &c. The shipping points are Keokuk, Fort Madison, Burlington, Muscatine, Davenport, Clinton, Bellevue, Dubuque, McGregor, &c.; and at all of these places an active trade is also carried on with the interior, with which they are connected to a large

extent by river steamboat routes and by railroad. The state has three United States ports of delivery, Burlington, Dubuque, and Keokuk. The total number of vessels registered, enrolled, and licensed in 1873 was 78, having a tonnage of 5,489; 70 of these belonged to Dubuque. At this point boat building is carried on to some extent; five vessels of 497 tons, including four steamers, were built here in 1873. In November, 1873, 75 national banks were in operation; paid-in capital, \$6,017,000;

bonds on deposit, \$5,909,000 ; circulation outstanding, \$5,363,885. The bank circulation of the state amounted to \$5,674,385, being \$4 75 per capita, 8 per cent. of the wealth of the state, and 88·3 per cent. of the banking capital. There were 23 banks, of which 15 were savings banks, organized under the laws of the state, having \$1,015,956 capital stock paid in, with assets amounting to \$3,879,033.—In the development of its railroad system Iowa has made rapid progress. The total mileage of main track has increased from 68 m. in 1855 to 655 in 1860, 891 in 1865, 2,683 in 1870, 3,160 in 1871, 3,643 in 1872, and 3,744 in 1873. In 1856 and 1864 grants of lands were made by congress to the state to aid in the construction of railroads; these lands were in turn granted by the state to various companies for the construction of five great trunk lines crossing it from east to west and extending from the Mississippi to the Missouri river. Four of these are now in operation, and the fifth is partially built. The most southerly is the Burlington and Missouri River railroad, which extends from Burlington to Council Bluffs. The Chicago, Rock Island, and Pacific, and the Chicago and Northwestern, have the same place as their western terminus in Iowa, the former extending from Davenport

and the latter from Clinton. At Council Bluffs, which is on the opposite side of the Missouri river from Omaha, Nebraska, these three lines connect with the Union Pacific railroad, which has its eastern terminus at this point, a bridge having been constructed across the Missouri. The next grand line crossing the state is the Iowa division of the Illinois Central railroad, which extends from Dubuque to Sioux City. The projected line will connect McGregor, opposite Prairie du Chien, Ill., with Sioux City; it has been completed to Algona, 169 m. from the Mississippi, and is now (1874) operated by the Milwaukee and St. Paul railroad company. All these great channels have communication with Chicago and the great eastern commercial centres, and for their accommodation the Mississippi has been spanned with several bridges. The numerous railroads crossing these trunk lines give Iowa extended facilities of communication with the states lying to the north and the south. The assessed value of the 3,643 m. of railroad in the state in 1872 was \$18,842,592. The railroads lying wholly or partly within the state, together with their termini, are indicated in the following table, which shows also the number of miles completed within the state in 1873, and the entire length of the various lines:

NAME OF CORPORATION.	TERMINI.	Length completed in state, miles.	Total length between termini when different from preceding.

Sioux City and St. Paul.....			

—The present constitution of Iowa was adopted in convention, March 5, 1857. It grants the right of voting to every male citizen of the United States who has resided in the state six months and in the county 60 days. The general election is held on the second Tuesday in October, except in the years of the presidential election, when it occurs on the Tuesday next after the first Monday in November. The legislature consists of a senate of 50 members elected for four years, half biennially, and a house of 100 members elected biennially. Senators must be 25 and representatives 21 years of age, and otherwise must have the qualifications of voters. In all elections by the legislature votes are given *viva voce*. The legislature meets on the second Monday of January biennially (even years). The governor and lieutenant governor are chosen by a plurality of votes, and hold office for two years. They must be at least 30 years of age, and have been citizens and residents for two years next preceding election. The salary of the governor is \$3,000 per annum. The secretary of state, auditor of state, treasurer of state, register of state land office, and superintendent of public instruction are elected by the people for two years, and have each a salary of \$2,200. The lieutenant governor and attorney general (salary \$1,500) are elected for two years, and the supreme court clerk and reporter are elected for four years. The adjutant and inspector general (salary \$2,000) and state librarian (salary \$1,200) are appointed by the governor for two years. The judicial power is vested in a supreme court, district courts, and such other courts, inferior to the supreme court, as the legislature may establish. The supreme court, with appellate jurisdiction only in chancery cases, consists of four judges elected by the people for six years, one every second year, and the one having the shortest time to serve is chief justice. Judges of the district court are elected in single districts (of which there are now 13) for four years. The salary of supreme court judges is \$4,000, and of district judges \$2,200 per annum. A district attorney is elected in each judicial district for four years. There are also 13 circuit courts, each with one judge, the circuits having the same boundaries as the judicial districts. The county officers consist of a board of supervisors, auditor, clerk, treasurer, recorder, sheriff, superintendent of common schools, surveyor, and coroner. The counties are subdivided into townships, each of which elects three trustees, a clerk, justices of the peace, constables, and road supervisors. Among the general provisions of the constitution are the following: The credit of the state shall not be given for any purpose; deficits in the revenue may be made up by borrowing money, but the sum not to exceed \$250,000 at any one time; debt may be contracted to repel invasion or suppress insurrection; no corporation shall be created by special law; stockholders in banks shall be individually liable to

double the amount of the stock, and billholders shall have preference over other creditors; suspension of specie payment shall not be permitted; no new county shall be made of less than 432 sq. m., nor shall any existing county be reduced below that size; no lease of agricultural lands shall be for more than 20 years; aliens, residents of the state, may hold and transmit real estate; imprisonment for debt is prohibited except in cases of fraud; parties in suit may be witnesses; duellists are disqualified from holding any office; the legislature is prohibited from granting divorces, or authorizing lotteries; in all prosecutions for libel the truth may be given in justification. The constitution requires a census to be taken in 1875 and every ten years thereafter; but a state census has been taken at frequent intervals. In 1872 the death penalty as a punishment for crime was abolished by a vote of 29 to 17 in the senate and 66 to 22 in the house; and it was provided that all crimes previously punishable with death should be punished by imprisonment for life, and that in these cases the governor shall not be empowered to grant a pardon except upon the recommendation of the general assembly. The executive council is required on the first Monday of March in each year to assess all the property of every railroad company in the state used in the operation of their roads; and it is made the duty of the officers of the company to report under oath the necessary facts for such assessment. All railroad property is taxable at the same rates and in the same manner as that of individuals. No distinction is made in law between the husband and the wife in regard to property. One third in value of all the real estate of either, upon the death of the other, goes to the survivor in fee simple. Neither is liable for the separate debts of the other. The wife may make contracts and incur liabilities which may be enforced by or against her in the same manner as if she were unmarried; and so a married woman may sue and be sued without the husband being joined in the action. Iowa is represented in congress by nine representatives and two senators, and has therefore 11 votes in the electoral college.—The total bonded debt of the state in November, 1873, was \$543,056. The receipts into the state treasury during the two years ending Nov. 1, 1873, amounted to \$2,407,938, and the disbursements to \$2,446,680. The income was from the following sources:

State tax levy.....	\$1,595,010 81
Interest on delinquent taxes.....	54,195 19
Insane dues from counties.....	226,250 12
Peddlers' licenses.....	382 66
Sale of laws and revisions.....	765 58
Railroad taxes received in 1872.....	34,230 63
Taxes on insurance companies.....	76,721 23
Auditor's fees from insurance companies.....	31,091 32
Secretary of state, fees.....	3,253 80
Register of the state land office, fees.....	215 25
United States war and defence fund.....	102,247 86
Sale of arms, &c.....	5,213 06
Other sources.....	278,361 85
Total.....	\$2,407,938 86

The total valuation of taxable property after equalization by the state board of assessment, and the state tax thereon, for a series of years have been as follows:

YEARS.	Total valuation.	Rate.	State tax.
1858.....	*\$214,625,730	1½ mills	*\$321,938 60
1859.....	197,823,250	1½ "	296,734 81
1860.....	*193,325,530	1½ "	*290,073 30
1861.....	177,451,003	2 "	354,901 92
1862.....	+175,000,000	2 "	350,000 00
1863.....	167,108,974	2 "	334,217 90
1864.....	+165,000,000	2 "	330,000 00
1865.....	215,063,401	2 "	490,126 83
1866.....	+220,000,000	2½ "	550,000 00
1867.....	256,517,184	2½ "	641,292 83
1868.....	+260,000,000	2½ "	650,000 00
1869.....	294,532,252	2 "	589,064 44
1870.....	+300,000,000	2 "	600,000 00
1871.....	348,642,723	2 "	697,285 55
1872.....	366,076,206	2½ "	915,190 51
1873.....	364,336,580	2½ "	728,672 78

The valuation for 1873 included 33,730,669 acres of land; reported value, \$217,907,148; reported value of town lots, \$47,642,585; equalized value of lands and town lots, \$273,797,687; value of personal property, \$71,683,367; of railroad property, \$18,885,526; reported total value, \$356,088,626; total equalized value, \$364,336,580. The entire tax in 1872 amounted to \$10,711,925, as follows: state tax, 2½ mills, \$909,464; county, \$1,460,734; insane hospital, \$217,691; county school, \$402,435; district school, \$3,954,210; bridge, \$705,445; road, \$360,700; special, \$433,108; judgment and bond, \$598,471; corporation, \$340,359; railroad, \$1,329,303.—The college for the blind at Vinton receives students who are citizens of the state free of charge for board and tuition. This school is strictly educational, and not for the treatment of disease. Since its opening in 1853, 269 pupils have been admitted; the number attending in 1873 was 112, who were instructed by 10 teachers. The total current expenditures for the two years ending Nov. 4, 1873, amounted to \$51,175. Instruction is afforded to the deaf and dumb of the state, between the ages of 10 and 25 years, by the institution at Council Bluffs; such persons may receive their board and instruction free of charge for a period of seven years. Established in 1855, this institution in 1873 had 7 instructors and 119 pupils; the current expenses for the two years ending Nov. 1, 1873, were \$56,221. Iowa has two hospitals for the insane: one at Mt. Pleasant, which at the end of 1873 had 495 inmates, and for which \$229,441 had been expended during the previous two years; and the other at Independence, which was opened in May, 1873, and at the close of the year had 152 patients. Of the patients treated in the former during the two years ending with 1873, 28.16 per cent. had recovered, 21.65 per cent. had improved, and

* Partly estimated; some counties not having reported.

† Estimated, the valuation of realty being the same as the year previous.

27.64 per cent. had remained stationary. Iowa has three soldiers' orphans' homes, at Cedar Falls, Davenport, and Glenwood. The support of these institutions during 1873 cost the state \$146,050, besides \$12,000 expended for improvements and \$550 for libraries. At the end of the year there were in these homes 508 children, of whom 256 were at Cedar Falls, 154 in Davenport, and 98 at Glenwood. There is a reform school for boys at Eldora, and one for girls near Salem. In 1873 there were in the former 146 boys and in the latter 11 girls. The cost of the boys' school for the two years ending Nov. 1, 1873, was \$32,031, and of the girls' \$2,250. The penitentiary at Fort Madison has 318 cells, and at the close of 1873 contained 276 convicts, of whom 63 were sentenced by the United States. The labor of the convicts who are employed within the prison is disposed of by contract at 40½ cents a day for each laborer. The number thus employed in 1873 was 258, and the earnings from this source for two years amounted to \$54,081. These contracts will expire Jan. 1, 1875, when it is believed that much higher rates will be realized. The institution is self-sustaining. The total receipts for the two years ending Nov. 1, 1873, were \$134,899, and the expenditures \$118,912. Another penitentiary is in process of construction at Anamosa, in Jones county.—According to the census of 1870, the total number of educational institutions in Iowa was 7,496, having 9,319 teachers, of whom 5,663 were females, and 217,654 pupils. There were 7,322 public schools, with 8,866 teachers and 205,923 pupils; 21 colleges, with 139 teachers and 3,061 students; 34 academies, with 103 teachers and 2,333 pupils; and 100 private schools, with 136 teachers and 4,872 pupils. The total income of all the educational institutions was \$3,570,093, of which \$63,150 was from endowment, \$3,347,629 from taxation and public funds, and \$159,314 from tuition and other sources. The system of public schools is substantially the same as that adopted in 1858. The constitution of 1857 vested the management of the educational institutions of the state in a board of education, consisting of the governor, the lieutenant governor, and an elected member from each judicial district in the state. This body was not empowered to levy taxes or make appropriations of money for school purposes, but was required to provide for the education of all the youths of the state through a system of common schools; such schools to be organized and kept in every school district at least three months a year, and any district failing to do so for two consecutive years may be deprived of its portion of the school fund. The permanent school fund embraces all lands granted to the state by the general government for schools, and all estates of deceased persons who have died without leaving a will or heir. The money paid for exemption from military duty, and the net proceeds of all fines collected in the several coun-

ties for any breach of the penal laws, must be applied to the support of common schools or the establishment of libraries, as the board of education may provide. Educational funds must be distributed among the districts in proportion to the number of persons between 5 and 21 years of age. The board of education was abolished in 1864. The school system of the state contemplates a threefold plan of superintendence, state, county, and district. There is a state superintendent of public instruction, and a superintendent for each county, while the general supervision of the district is vested in a board of directors. The following are the most important statistics of the public schools for 1873:

Number of school districts.....	2,536
" of schools graded.....	419
" of schools ungraded.....	8,397
" of school houses.....	5,856
Average number of months schools have been taught.....	6½
Number of teachers (6,091 male and 10,193 female).....	16,284
Average compensation of males per month.....	\$36 28
" of females " ".....	\$27 63
Number of persons between 5 and 21 years of age.....	491,344
" of pupils enrolled in public schools.....	347,572
Total average attendance.....	204,204
Percentage of enrollment on total enumeration.....	71
" of attendance upon enrollment.....	58
" " " enumeration.....	42
Number of private schools.....	121
" of teachers in same.....	864
" of pupils " ".....	12,132

The amount of the permanent school fund on

Nov. 1, 1873, was \$3,294,742, on which the interest for 1873 amounted to \$275,789. The total expenditures for school purposes amounted to \$4,229,455, of which \$2,248,676 was for teachers' salaries. The total cost of education in 1873 was \$3 38 per capita based on the total population, \$8 60 on the school population (between 5 and 21 years old), \$12 17 on the enrollment, \$20 71 on the average attendance, \$17 76 on the number of heads of families, and \$15 17 on the number of adult males. Based on taxable property, the cost was 11·59 mills on the dollar, including 6·17 mills for tuition, 2·24 for incidentals, and 3·18 for the erection of school houses. Although normal instruction is afforded by several institutions in the state, Iowa has no state school devoted exclusively to the training of teachers. The state teachers' association meets annually, and there are numerous county institutes. Teachers in the public schools are required to hold certificates obtained by examination, and issued by county superintendents for a term not exceeding one year. Prior to September, 1873, examinations were conducted and perpetual state certificates granted by a state board of examiners consisting of the faculty of the state university; but this board has been abolished. The most important educational institutions of Iowa, with the number of instructors and pupils during the year 1873-'4, were:

TITLE.	Location.	Denomination.	When founded.	No. of faculty.	No. of students.

Norwegian Luther college.....	Decorah.....	Lutheran.....	1861	6	185
Burlington university.....	Burlington.....	Baptist.....	1853	5	51

The state university comprises academical, normal, medical, and law departments. In the first named, besides a preparatory course of two years, there is a four years' curriculum affording three courses, classical, philosophical, and scientific. The course in the law department covers one, and in the medical department two years. Of the 551 students of the university in 1873, 85 were in the law, 70 in the medical, and 17 in the normal department. The income from June 20, 1871, to Oct. 1, 1873, amounted to \$123,499, and the disbursements to \$103,415. The state agricultural college has received the congressional land grant for the promotion of instruction in agriculture and the mechanic arts.

In the regulation of this institution two interesting experiments have been made, and are regarded as successful: 1, the union of manual labor with intellectual exercise as a part of the course, students being required to devote an average of 2½ hours a day throughout the college year to manual labor; 2, co-education of the sexes. The institution has extensive grounds and valuable collections. Courses of instruction are provided in agriculture, four years; horticulture and forestry, stock breeding, mechanical engineering, civil engineering, mining engineering, architecture, "general science for ladies," military tactics and engineering, normal course, and course in bee-keeping. The Norwegian Luther college, the largest Norwe-

gian institution of the kind in the country, was established by the Norwegian Evangelical Lutheran synod of Iowa and adjacent states, and is under the direction of that body. It is supported by voluntary contributions, and affords instruction free to all students. The plan of the Iowa Wesleyan university embraces a department of the liberal arts, comprising classical, scientific, normal, and preparatory courses; a department of technology, including courses in fine art and industrial art; and departments of theology, law, and medicine. Both sexes are admitted. Instruction in theology is afforded by the Wartburg seminary (Lutheran) at Casstown, the Swedish Lutheran mission institute at Keokuk, the German theological school of the Northwest (Presbyterian) at Dubuque, and the theological department of the Wesleyan university (Methodist Episcopal) at Mt. Pleasant, with courses in English and German; in law, by the law departments of the state and the Wesleyan university; in medicine, by the medical department of the state university, the department of pharmacy in the Wesleyan university, and the college of physicians and surgeons established in Keokuk in 1849, which had 10 instructors and 142 pupils in 1873; and in science, by the state agricultural college.—According to the census of 1870, there were in Iowa 233 newspapers and periodicals, having an aggregate circulation of 219,090, and issuing 16,403,380 copies annually. There were 22 daily, with a circulation of 19,800; 3 tri-weekly, 1,650; 1 semi-weekly, 1,000; 196 weekly, 187,840; 3 semi-monthly, 3,400; 5 monthly, 3,950; 2 bi-monthly, 750; 1 quarterly, 700. The state census of 1873 returned as published in Iowa 22 daily newspapers, 2 tri-weekly, 6 semi-weekly, 272 weekly, 2 semi-monthly, 19 monthly, and 1 bi-monthly. The total number of libraries in 1870 was 3,540, containing 673,000 volumes. Of these, 2,387 with 295,749 volumes were private, and 1,153 with 377,851 volumes were other than private, including 1 state, with 11,000 volumes; 23 town, city, &c., with 22,808; 11 court and law, with 944; 15 school, college, &c., with 18,747; 999 Sunday school, with 278,251; 85 church, with 25,584; and 18 circulating libraries, with 20,367 volumes. The chief libraries are the state library in Des Moines, which in 1874 had 12,000 volumes, exclusive of 4,000 duplicates; the Keokuk library association, 7,000; state historical society, Iowa City, 3,300; public library of Burlington, 5,398; and Jefferson county library association, Fairfield, 3,480. The state historical society at Iowa City is partly supported and controlled by the state. A chief object is the collection and preservation of historical works, manuscripts, relics, &c., pertaining to the history of the state.—In 1870 the state contained 2,763 religious organizations, having 1,446 edifices with 431,709 sittings, and property valued at \$5,730,352. The various denominations were represented as follows:

DENOMINATIONS.	Organizations.	Edifices.	Sittings.	Property.
Baptist, regular.....	307	147	44,840	\$622,700

—Iowa derives its name (said to mean in the language of the Indians "the beautiful land") from the river so called, and was originally a part of the vast territories included in Louisiana, ceded to the United States in 1803. The first settlement of whites within the present limits of the state was made by Julien Dubuque, a Canadian Frenchman, who in 1788 obtained a grant of a large tract, including the present city of Dubuque and the rich mineral lands in its vicinity. Here he built a small fort, and carried on the mining of lead and trade with the Indians until his death in 1810. In 1834 the territory now included in Iowa was placed under the jurisdiction of Michigan, and in 1836 under that of Wisconsin. No steps were taken toward its further settlement till the spring of 1833, when several companies of Americans from Illinois and other states settled in the vicinity of Burlington; and at a later period settlements were made at other points along the Mississippi. On June 12, 1838, Iowa was erected into a separate territory; and on July 4 ensuing the new government was formally installed at Burlington. Under its territorial organization Iowa included all the country N. of Missouri, between the Mississippi and the Missouri and to the British line, and consequently the greater part of the present state of Minnesota and the whole of Dakota territory, with an area of 194,603 sq. m. In 1839 the government removed to Iowa City. In 1844 a state constitution was formed, and a petition sent to congress for admission to the Union. This was not granted, on account of the constitutional limits assumed; and by an act of March 3, 1845, congress defined the boundaries that would be acceptable. The next year the proposed boundaries were approved by a convention assembled for the purpose; and on Dec. 28, 1846, Iowa was admitted into the Union. The capital was removed to Des Moines in 1857. On Jan. 24,

1855, an act was passed by the legislature submitting to the people the question of calling a constitutional convention. The proposition having been approved, an election of delegates was held in November, 1856. On Jan. 19, 1857, the convention met in Iowa City and framed the present constitution, which was ratified on Aug. 3, 1857, by a vote of 40,311 to 38,681. The word "white," where it had been used in defining the qualifications of electors, the basis of representation, and the obligation of militia duty, was stricken out by acts of the legislature, subsequently approved by the people in 1868. The question of revising the constitution was submitted to the people in 1870, when a majority voted against it. A report on the geological survey of the state during 1866-'9, by Charles A. White, state geologist, was published in Des Moines in 1870 (2 vols.).

IOWA. I. A S. W. county of Wisconsin, bounded N. by Wisconsin river, and drained by the branches of the Pekatonica; area, 720 sq. m.; pop. in 1870, 24,544. The surface is irregular and thinly timbered. Lead is abundant, and copper and zinc are found. The Prairie du Chien division of the Milwaukee and St. Paul railroad passes along the N. border, and the Mineral Point railroad terminates at the county seat. The chief productions in 1870 were 760,166 bushels of wheat, 705,792 of Indian corn, 803,951 of oats, 40,867 of barley, 35,857 of flaxseed, 145,141 of potatoes, 48,758 lbs. of wool, 73,896 of hops, 84,023 of flax, 547,388 of butter, and 38,054 tons of hay. There were 9,871 horses, 10,064 milch cows, 17,460 other cattle, 13,756 sheep, and 28,235 swine; 22 manufactories of carriages, 7 of cabinet furniture, 5 of pig lead, 1 of paints, 8 of saddlery and harness, 3 flour mills, 4 breweries, and 2 zinc-smelting establishments. Capital, Mineral Point. **II.** An E. county of Iowa, intersected by the river of the same name and the N. fork of the English river; area, 576 sq. m.; pop. in 1870, 16,644. It has an undulating and well wooded surface, and a fertile soil. The Chicago, Rock Island, and Pacific railroad passes through the county. The chief productions in 1870 were 531,148 bushels of wheat, 1,281,123 of Indian corn, 267,049 of oats, 111,882 of potatoes, 499,379 lbs. of butter, 31,877 of wool, and 30,703 tons of hay. There were 6,564 horses, 6,481 milch cows, 10,995 other cattle, 8,806 sheep, and 21,590 swine; 4 manufactories of carriages, 4 of saddlery and harness, 1 of woollen goods, 4 of brick, 4 flour mills, and a cotton and woolen print works. Capital, Marengo.

IOWA CITY, the capital of Johnson co., Iowa, and from 1839 to 1857 the seat of the territorial and state government, situated on the left bank of the Iowa river (here navigable by steamboats), 80 m. from its mouth, and on the Chicago, Rock Island, and Pacific railroad, 130 m. E. of Des Moines; pop. in 1850, 1,250; in 1860, 5,214; in 1870, 5,914. Since the census the city has been enlarged, and the population

now (1874) is about 9,000. It is built upon the highest of three plateaus, 150 ft. above the river, and is surrounded, at the distance of a mile, by an amphitheatre of hills. It is the seat of the state university, which has an attendance of 600 students in the academical, law, and medical departments, an extensive laboratory, and a library of 6,500 volumes. The university occupies four buildings, the largest having been erected by the federal government for the territorial capitol. In connection with its medical department is Mercy hospital, with roomy wards and private apartments. (See Iowa.) The county offices and court house are the other principal public buildings. There are several flouring mills in operation, and the river furnishes motive power for various other manufactories. The city contains two national banks, the state historical society's rooms, with a library of about 3,500 volumes, four ward schools, three academies, a commercial college, a daily and three weekly (one Bohemian) newspapers, a semi-monthly periodical (published by the students in the university), and 15 churches.

IOWA RIVER. See IOWA.

IOWAS, a tribe of American Indians, belonging to the Dakota family. They call themselves Pahucha, "Dusty Nose," but were called by some Algonquin tribes Iowas, and by others Mascoutin or Prairie Nadouessis. Marquette in 1673 lays them down as the Pahoutet, back of the Des Moines. They consisted of eight clans: the Eagle, Wolf, Bear, and Buffalo, still existing, and the Pigeon, Elk, Beaver, and Snake, now extinct. Each of these was distinguished by a peculiar way of cutting the hair. The Jesuit Father André preached to a band of them about 1675, and ten years later a delegation met and wept over Perrot, according to the Sioux fashion, at his temporary fort on the Wisconsin. Their country was then in about lat. 43° N., 12 days' journey west of Green bay. In 1700 they were on the Mankato, and like the Sioux were at war with all the western Algonquin tribes. Charlevoix mentions that the great pipestone quarry was on their territory, and says they were famous in all the west as pedestrians, being able to travel 25 or 30 leagues a day when alone; and the names of chiefs show that they pride themselves on their walking. They were constantly at war, and about the beginning of this century were involved with the Osages, and soon after with the Omahas and Sioux. They seem to have numbered then about 1,500. They defeated the Osages in 1803, but soon after lost severely by smallpox; some years later many of them were killed and taken by the Sioux, and in 1815 they were again decimated by disease. The United States made a treaty of peace with Wyingwaha or Hardheart and other chiefs, Sept. 16, 1815. By another treaty, made with Gen. Clark on Aug. 4, 1824, Mahaskah or White Cloud, the greatest chief in the annals of the tribe, and Manehana or Great Walker,

ceded all the Iowa lands in the territory of Missouri, for \$500 down and \$500 annually for ten years, the United States agreeing to support a blacksmith and assist the tribe with agricultural implements, cattle, &c. Their chief villages at this time were on the Iowa and Des Moines. The next year Clark and Lewis Cass endeavored to establish peace between them and the Sioux. A part of the Sacs and Foxes were then jointly interested with them in some of the territory between the Iowa and Des Moines, and have continued to be their friends and neighbors. The intrusion of whites on their valuable lead lands led to trouble and complaints; but the influence of liquor, with war and disease, was beginning to destroy the tribe. The Iowas, numbering 992, were removed by the treaty of Sept. 17, 1836, and placed on the west bank of the Missouri above Wolf river; but a part broke off the next year and became vagrants, living by theft and hunting on grounds of other tribes. Every year showed a decline, the chiefs leading in intemperance, and many of the tribe being killed annually in liquor. A Presbyterian mission and manual labor school, earnestly maintained from 1835 to 1866, failed to save this people. By 1846 they had declined to 706 in number. Their territory was then bounded E. by the Missouri and N. by the Great Nemahaw. By the treaty of March 6, 1861, the tribe, reduced then to 305 souls, ceded all but a reservation of 16,000 acres. In 1869 they agreed to sell this and remove, but subsequently retracted, merely giving part to the Sacs and Foxes, who actually sold their reservation. Out of a population of only 293 the Iowas in 1864 had 41 men in the United States armies, who were improved by the discipline, and adopted civilized customs. Since the tribe has been placed under the charge of the Friends, some progress is said to have been made in sobriety and industry. In 1872 they numbered 225, and were quite favorable to the school, which contained 63 pupils all dressed in civilized garb, and to the orphans' industrial home. They had 700 acres cultivated, 13 frame houses, and 20 log houses. Their produce amounted to \$2,685, and their stock was valued at \$7,900. The United States government holds \$57,500 for the Iowas, the interest of which is paid yearly to the heads of families; and the usual Indian goods are not now furnished, being replaced by useful articles.—An Iowa grammar by the Rev. S. M. Irvin and William Hamilton, illustrating the principles of the language, and a primer, were published at the Iowa mission in 1848.

IPECACUANHA, a name given by the aborigines of Brazil to various roots which possess emetic properties. The root thus designated in the pharmacopœias does not appear to be one of these, but of the *cephælis ipecacuanha*, called *poaya* in Brazil, a small plant of the natural order *rubiaceæ*, suborder *cinchonaceæ*. It grows in the thick and shady woods of Brazil and Colombia, flowering in January and Feb-

ruary, at which season the root is collected by the native Indians and taken to the chief ports for exportation. The pieces are a few inches long and of the size of straws, much bent and sometimes branched, and in the genuine article always knotted on the surface by rings and depressions which have given it the designation of annulated. The central portion is ligneous, and possesses the virtue of the plant in a much less degree than the cortical covering of the root. The different colors of this portion, sometimes red, brown, or gray, have led to the mistake of referring the root to different varieties of the plant according to these colors. The alkaloid principle, called *emetia*, has been separated in an impure state from the cortical part of the brown root in the proportion of 16 per cent., and from the red of 14 per cent. This principle, to which the emetic property of the plant is owing, is hardly to be obtained pure, but is probably a salt,

Cephaelis ipecacuanha.

the alkaloid uniting with many acids to form crystallizable salts. It appears as a white powder without odor, and of slightly bitter taste. The root of *psychotria emetica*, growing in Peru and Colombia, has been known as *ipecacuanha striata*, and the root of various species of *Richardsonia* as *I. undulata*. Various species of *ionidium* produce white ipecac. All of these roots are emetic, and the *I. striata* and *I. undulata* have been found to contain emetia. The British government has made successful experiments in raising ipecacuanha in India, and supplies of the drug will probably hereafter be furnished by that country. The first plants were propagated at the Edinburgh botanic garden and sent out in Wardian cases, but they have since been propagated in India. The plant is readily multiplied by cuttings of the rhizome, but is of exceedingly slow growth.—Ipecacuanha was introduced into medical practice in Europe by John Helvetius, grandfather

of the celebrated author of that name, and with such success that a large sum of money and public honors were bestowed by Louis XIV. upon the physician for giving publicity to the remedy, which he had kept secret. In large doses it is an active and quick but mild emetic; in smaller, a diaphoretic and expectorant; and in still smaller, a stimulant to the stomach. It acts when injected into the blood as well as when given by the stomach, and is consequently entitled to be called a specific emetic. In very large doses it diminishes the rapidity of the pulse. Animals may be killed by it. It is used not only to empty the stomach, but also in small doses in diseases of the bowels especially dysentery and diarrhœa. When first introduced into European practice, it was known as *radix antidysenterica*. Ipecac is employed also in affections of the respiratory organs, especially in croup and the bronchitis of children. Its preparations are, besides the powder, a wine, fluid extract, and sirup. It is combined with opium in Dover's powder. The dose of ipecacuanha as an emetic is 20 grs. or more; as an expectorant, $\frac{1}{2}$ gr. to 2 grs. The dose of the wine varies from a few drops to a tablespoonful, according to the indications of the case. The sirup is weaker than the wine.

IPHICRATES, an Athenian general in the first half of the 4th century B. C. At the battle of Cnidus he captured one of the Spartan trierarchs. In 393 he commanded the Athenian auxiliaries at the battle of Lechæum, in which the allies were defeated by the Lacedæmonians under Praxitas. The guerilla system subsequently adopted by the belligerents in that war seems to have suggested to Iphicrates the formation of a body of light-armed foot soldiers called *peltastæ*, with whom he attacked a division of the Lacedæmonian army near Corinth, and almost destroyed it. He next captured Sidus, Crommyon, and Cenoë from the Spartans; but the Athenians, listening to Argive calumnies, deprived him of his command. In 389 he was reinvited with authority, and sent to the Hellespont to counteract the operations of the Lacedæmonian Anaxibius, who was defeated by him and slain in the following year. After the peace of Antalcidas, Iphicrates entered into alliance with Cotys, a Thracian prince, who gave him his daughter in marriage, and allowed him to found the town of Drys in his territory. In 377 he was sent with 20,000 Greek mercenaries to aid the Persian satrap Pharnabazus in reducing Egypt to obedience. The policy of Iphicrates was too daring for the wary barbarian. The commanders quarrelled, and the Greek, fearing for his safety, fled to Athens, where he was denounced by Pharnabazus for causing the failure of the expedition. The Athenians promised to punish him, but in the next year (373) they appointed him to the joint command of the armament which they sent against Corcyra. That town was brought over to the Athenian alliance, and the fleet which the Syracusan tyrant Dionysius had sent

to the assistance of the Lacedæmonians was defeated. In the war which grew out of the seizure of Thebes by the Spartans, Iphicrates commanded the Athenian forces sent against the Thebans. He afterward commanded in Thrace and in the social war, in conjunction with Timotheus, Menestheus, and Chares, the last of whom sought to shield himself from the consequences of his ignorance by prosecuting his colleagues. Iphicrates was acquitted, and spent his latter days at Athens.

IPHIGENIA, a daughter of Agamemnon and Clytemnestra, or, according to some authorities, of Theseus and Helena. Agamemnon, having once killed a stag in the grove of Diana, sought to appease the offended goddess by vowing that whatever, most beautiful, was born to him in that year should be sacrificed to her. His daughter Iphigenia chanced to be born within the period specified; but the king from time to time put off the performance of his vow, until the Grecian armament was assembled in the port of Aulis to sail against Troy. The winds proving unpropitious, Calchas the seer was consulted, and replied that the sacrifice of the daughter of Agamemnon was indispensable to propitiate the gods. But Agamemnon still resisted, and only yielded to the importunities of Menelaus. When Iphigenia was about to be immolated, Diana herself intervened to save her, and bore her in a cloud to Tauris, where Iphigenia became her priestess. Her brother Orestes came thither in order to steal the image of Diana, which was believed to have fallen from heaven, and to transport it to Hellas. Iphigenia recognized him, and aided him in obtaining the desired image, with which they fled to Argos. Iphigenia afterward carried it to Sparta, where she acted as priestess of Diana till her death.

IPSAMBUL, *Abu Sambul*, or *Abusimbel*, a place in lower Nubia, on the left bank of the Nile, 30 m. S. W. of Derr, lat. 22° 22' N., lon. 31° 40' E., remarkable for two of the most perfect and magnificent specimens of Egyptian rock-cut temples. Both have front walls of sandstone, and the interiors are excavated from the solid rock. The smaller temple, which Wilkinson thinks was dedicated to Athor, stands 20 ft. above the level of the Nile, and has a front of 90 ft. adorned with six gigantic statues. There is an interior hall of six square pillars, a transverse corridor with a small chamber at each extremity, and an asylum. The whole is apparently almost as perfect as it was when completed. Burckhardt saw and first described this temple of Isis, as he believed it to be, on March 22, 1813, and 200 ft. in the rear he discovered the heads of four colossal statues, the bodies of which were buried in sand. These he judged to belong to the finest period of Egyptian sculpture. The rear wall, covered with well executed hieroglyphics, displayed a figure of hawk-headed Osiris surmounted by a globe, and Burckhardt predicted that the clearing away of the sand

would reveal a temple to that deity. In 1817 Belzoni, assisted by Capts. Irby and Mangles, removed 31 ft. of sand, when the top of the entrance was reached. This second and larger temple, standing 100 ft. above the water level, has a front 120 ft. long and 90 ft. high, surrounded by a moulding, and adorned with a cornice and frieze. In front, seated on thrones, are four colossal figures 65 ft. high, the largest in Nubia or Egypt. The third statue from the north has been shattered by an avalanche from the mountain, and a portion of the head lies in the lap of the figure. One of these colossi has a face 7 ft. long and measures 25 ft. 4 in. across the shoulders. According to Wilkinson, the figures are statues of Rameses II. The interior

Tomb, Ipsambul.

presents first the colonnade, the pilasters of which bear figures of Osiris 30 ft. high, and the walls exhibit sculptures representing battles and triumphs. Next is the great hall extending 200 ft. into the rock, with ranges of massive square columns adorned with statues. Beyond are an antechamber and the sanctuary with several side chambers. In the background is a colossal figure seated on a bench, and there are similar statues in the side chambers. In the centre of the sanctuary is a pedestal on which Heeren thinks a sarcophagus once stood, and hence he argues that the monument was not a temple but the sepulchre of a king. He believes, too, from the scenes of war and triumph sculptured on the walls, and

especially from four painted figures, one of which in red he takes to be a king, that the smaller monument also was a royal sepulchre. Burekhardt says that Ipsambul served as a refuge to the inhabitants of Beillany, 8 m. distant, against the annual incursions of a western tribe of Bedouins. In 1812, the year previous to his visit, the natives took refuge there with their cattle, and the Bedouins, after losing several men, failed to force the place.

IPSARA, or **Psara**, a barren and rocky island belonging to Turkey, in the Grecian archipelago, 10 m. W. of Scio; greatest length about 6 m., breadth 5 m. Those parts of it which are covered with a thin soil have been carefully cultivated, and before the Greek revolution the island was prosperous and densely populated, forming one of the most important marine stations under the control of Greeks. During the war it earned a national fame by the devotion and bravery of its mariners, but was captured and almost depopulated by the Turks (July 3, 1824); since that time it has been of little importance. There is but one town upon the island, also called Ipsara, and having hardly more than 500 inhabitants. It is situated on the S. side, where a small bay affords good anchorage; but it has little commerce, and the people are chiefly supported by fishing.

IPSUS, a town of ancient Phrygia in Asia Minor, probably about 10 m. S. E. of Synnada, and a short distance N. W. of the modern village of Bulavadin, 28 m. E. of Afium-Karahissar. It is famous on account of the battle fought in 301 B. C. (or in 300, as Grote conjectures), in the plain near it, when Antigonos and his son Demetrius were disastrously defeated by the forces of Seleucus, Cassander, Lysimachus, and Ptolemy. Antigonos fell, and the victory of his enemies was followed by a new division of the dominions of Alexander the Great, which terminated a bloody struggle of 20 years. In the 7th and 8th centuries Ipsus was the seat of a Christian bishop.

IPSWICH, a town of Essex co., Massachusetts, on both sides of Ipswich river, at its mouth, and on the Eastern railroad, 25 m. N. N. E. of Boston; pop. in 1870, 3,720. The river, which is here crossed by two stone bridges, one built in 1764 and the other in 1861, affords valuable water power, and in a bay of the same name at its mouth there is an excellent harbor. A number of vessels are owned here, and the town is interested to some extent in the coasting trade, and has small ship yards. There is a woollen mill, producing repellants, but the principal manufactures are of hosiery, employing 14 establishments, and of boots and shoes. The town contains a county insane asylum, a county house of correction, a female seminary established in 1828 and having in 1872 9 instructors and 60 pupils, a classical school founded in 1650, 10 public schools, including a high school, a weekly newspaper, a public library, and six churches. It was settled in 1633. Its Indian name was Agawam ("fishing station").

IPSWICH, a parliamentary borough and river port of England, capital of the county of Suffolk, on the river Orwell, 10 m. from the sea and 65 m. N. E. of London; pop. in 1871, 43,136. It is situated on a gentle declivity near the junction of the Orwell and Gipping, the latter of which, according to Camden, gave the town its name, which was originally Gippeswich. The streets are generally narrow and irregular, but are well paved and are lighted with gas. It has 42 churches and places of worship, a mechanics' institute, a working men's college, large iron founderies and soap factories, breweries, corn mills, and ship-building docks. Among the principal buildings are Queen Elizabeth's grammar school, the town hall, hall of commerce, corn exchange, county jail, hospital, assembly room, and barracks. The grammar school was founded originally in the reign of Edward IV., and was revived by Cardinal Wolsey, who intended to make it a

ny, rivalling Brisbane in business importance. It is the starting point of the southern and western railways.

IRAK-AJEMI, a central province of Persia, comprising a portion of the great desert, and bounded N. by a range of mountains dividing it from the provinces on the Caspian sea, E. by Khorasan, S. and S. W. by Fars and Khuzistan, and W. and N. W. by Luristan, Ardehan, and Azerbaijan; area estimated at about 100,000 sq. m., pop. at 1,250,000. The surface consists chiefly of a high table land traversed by several mountain ridges and fertile valleys. The Kizil Uzen in the north and the Kerah in the southwest are the principal rivers. The country is almost destitute of trees, and a considerable portion of arable land is uncultivated, but there are excellent pasture lands. Some of the valleys which are well watered produce large crops of rice, wheat, and other grains; and fruits, opium, tobacco, cotton, saffron, and silk are staples. Ispahan, Teheran, Hamadan, Casbin, Kermanshah, and Kum are the principal towns.

IRAK-ARABI, or **Irak-i-Arabi**, the Arabic name, and a common designation among orientalists, for the S. E. portion of Asiatic Turkey, and some adjoining territory to the east. It corresponds to ancient Babylonia and Elam or Susiana, and includes the pashalic of Bagdad, excepting the northern portion, and the S. W. frontier land of Persia, principally Khuzistan. It comprises therefore the alluvium at the head of the Persian gulf as far north as about lat.

Queen Elizabeth's Grammar School, Ipswich.

nursery for Christchurch college, which he had founded at Oxford. Its charter was confirmed by Queen Elizabeth. The present building, the corner stone of which was laid by Prince Albert in 1851 on a different site from the ancient school, is 168 ft. front by 110 ft. deep. It accommodates, besides the grammar school, a public library and museum. The town has considerable foreign and coastwise trade, chiefly in grain, coal, timber, and local manufactures. Ipswich was sacked by the Danes in the years 991 and 1000.

IPSWICH, a town of Queensland, Australia, on the river Bremer, 25 m. W. of Brisbane; pop. in 1871, 5,092. It has several churches and chapels, a hospital, a grammar school, a mechanics' institute with a library of 2,000 volumes, and two newspapers. Ipswich was incorporated into a municipality in March, 1860, and is now the second town of the colo-

ny, in the neighborhood of Hit on the Euphrates, and between the Syrian desert on the west and the mountain ranges of Kurdistan, Luristan, and Khuzistan on the east. This alluvium is said to increase with extraordinary rapidity, and it is supposed that its growth was still more rapid in ancient times, and that when the first Chaldean monarchy was established the Persian gulf reached 120 or 130 m. further inland than at present. Rawlinson says of this region that nothing is more remarkable than its featureless character. It is a dead level, broken only by single solitary mounds, the remains of ancient temples or cities, and by long lines of embankment marking the course of ancient and recent canals. Near the streams and canals are lands of great fertility, but the rest, except in early spring, is almost as parched and arid as the most desolate districts of Arabia. The principal rivers are

the Tigris and Euphrates. A wide and deep channel, branching off near Hit, skirting the Syrian desert, and entering the Persian gulf by a separate mouth, was probably the ancient western limit. The part east of the Tigris is the most fertile, and forms in a large measure the storehouse of the remainder of this district. Nearly all of Turkish Khuzistan, however, is but little cultivated, though its soil has every characteristic of luxuriant fertility. The climate and products of the region are mainly described in the articles upon the two principal towns, Bagdad and Bassorah.

IRAN. See PERSIA.

IRANIC RACES AND LANGUAGES. The Iranic or Persian races form a branch of the Aryan or Indo-European family. They inhabit a territory in the immediate vicinity and west of the Indic races or Aryans proper. The first traces of the Iranic branch are found north of the Hindoo Koosh, near the elevated plateau of Pamir, and at the sources of the Oxus. In historic times the Iranians appear on the shores of the Oxus and of the rivers of upper Sogdiana, and spreading southwest through Badakhshan and Balkh, they people the entire country of the vast plateau known in a limited sense as Iran or Persia, excepting the S. E. corner, inhabited by the Brahooses, a Deccanese or Dravidian race. The Afghans have an Iranic language strongly interwoven with Sanskritic elements, for which reason some class them among the Indic races. Beyond the Persian district the Iranic branch extends over the mountainous region of Armenia into Asia Minor. It is probable that in the flourishing period of the Persian empire the Iranic races were spread also over the plateau on the Kur as far N. as the Caucasus; it is less probable that, as some suppose, they were scattered over the regions beyond the Caucasus, and mingled with the Slavs. Colonies of Iranians, however, were to be found as far as the Crimea, and mingled with the Thracians. It is thus established that the Iranians were in ancient times the connecting link between the Indo-Europeans of Asia and of Europe. At an early period the Iranians and Indians probably formed but a single group of races. The *Arya* of the Indic was the *Airya* of the Iranic race, and apparently they had the same religion. In what period their separation took place is unknown.—The first Iranic race that appears in history is that of the Medes. Their earliest territory is not clearly defined, but it probably comprised very nearly the same regions as their strictly historical habitat, reaching in the east as far as the Caspian gates, and in the north not quite as far as the mountains N. of Atropatene. The southern boundary was Susiana, and in the west the territory was separated from that of the Assyrians and Babylonians by the Zagros. According to Berosus, the Medes were an important race as early as 2400 B. C., at which time, he says, there was a Median dynasty in Babylonia. Syncellus calls Zoroaster

the founder of this dynasty; but though this name may have been furnished by Berosus himself, as Eusebius intimates, it does not follow that this Zoroaster was identical with the founder of the Iranian religion. More important than this single statement by Berosus are the contents of the Assyrian cuneiform inscriptions, which do not speak of the Medes as the conquerors, but as the subjects of the Assyrian empire. The oldest notice is probably one found in the inscription of the elder Tiglath-pileser, about 1100 B. C., in which a country named Amadana is spoken of in connection with Elam as a conquered territory. The Medes are mentioned again on the black obelisks of the 9th century, and more frequently in the inscriptions of Sargon toward the close of the 8th century. He and his successors Sennacherib and Esarhaddon speak of Media as if it were a distant country, and the Assyrians evidently did not consider it as important to conquer as Asia Minor and Egypt. It is therefore probable that the Semitic race was spread at that time much further over the mountainous districts of the Zagros than they were in more recent historical times. The Assyrian inscriptions agree with the statement of Herodotus that the Medes were at an early period subjects of Assyria. He adds that they were the first people to cast off the yoke after 520 years, and with this period of the revolt of the Medes he begins the history of the foundation of the Median empire. (See MEDIA.)—The oldest sources we possess for the history of the Iranians represent them as divided into several races. Those most frequently mentioned are the races of the western territory. Herodotus distinguishes among the Medes the Busæ, the Paretaceni, the Struchates, the Arizanti, the Budii, and the Magi. The Persians he divides into Pasargadæ, Maraphians, Maspian, Panthialæans, Derusiæans, and the Germanians, all of whom were engaged in husbandry, and four nomadic tribes, the Daans, Mardians, Dropicans, and Sagartians. The special territories occupied by these tribes are not known. The remark of Herodotus that the Pasargadæ were the principal tribe, and that the Achæmenides were one of its clans, shows that each of these tribes consisted of several subdivisions. The Iranic races are also to this day subdivided into numerous tribes. The Indus is now the eastern boundary of these races. Near this river dwell the Belooches and Afghans. In the *darmawen* or borderland of India are several Afghan tribes which are sometimes collectively designated as Lohani, and others further west, on the Solyman mountains, forming together the transition from the Indic to the Iranic race. A very few of them are still nomadic; the others are husbandmen and traders. Still further west are the Afghans proper, and S. of them the Belooches, the latter not of purely Iranic origin. (See AFGHANISTAN, and BELOOCHISTAN.) The Afghans are a well built people, with an elongated head, horizontal eyes, and

a dark velvet-like skin. The Tajiks are also of Iranian blood and speech. Khanikoff has completely disproved the tradition hitherto accepted by many scholars, that the Tajiks are a Semitic people from Babylonia. They are met with among the Afghans and Belooches, but are found in largest number in Bokhara and Badakhshan, and many have settled in Khokan, Khiva, and Chinese Tartary. They are of good middle height and powerful frame, but have a broader head than the Afghans, and a thicker cheek and nose. In Bokhara and Khiva they form the literary class. They compose the largest part of the population of Cabool, Candahar, Ghuzni, Herat, and Balkh. Their superstitious practices clearly show that fire worship was their ancient form of religion; they are now Sunnis. The Barekis and the Permulis are considered branches of the Tajiks.—Further west, mainly on the borderland of Afghanistan, Khiva, and Persia, live the Aimags, whose language is of a very ancient type and but little mixed with Arabic. They consist of four peoples, the Timuri, Timeni, Ferozkohi, and Jamshidi. Among the Iranic populations of Persia, the Bakhtiaris and Feilis of Luristan deserve special mention. The Persians are considerably fairer than the Afghans, and their features are more regular, their physiognomy having been much improved by admixtures of Georgian and Circassian blood. (See PERSIA.)—Modern research has established that the Kurds also belong to the Iranian race. They are found in Khorasan, and inhabit the northern slopes and valleys of the Elburz, but the bulk of the eastern Kurds live on the Zagros mountains. The western Kurds have inhabited for a long period a portion of the Armenian mountain ranges on the northern limit of the Mesopotamian desert. (See KURDISTAN.) Khanikoff praises the beautiful heads and prepossessing features of the Kurds. The Yezids, who dwell in the Sinjar mountains, N. of Mosul, are also classed with the Kurds as Iranians. Among the Kurds live an agricultural people, called Gurans, whose dialect is more closely related to Persian than the Kurdish.—N. of the Kurds the principal Iranic populations are the Armenians (see ARMENIA), the inhabitants of the southern shores of the Caspian sea, the Tats, who live in Baku, and the Ossetes, on both sides of the Caucasus, near the Dariel pass. These generally surpass the Persians in complexion. The large black eyes of the Armenians are admired.—LANGUAGES. The recovery of the ancient languages of Persia is mainly an accomplishment of this century, and is principally due to the knowledge of Sanskrit. The two oldest phases of Iranic speech lay buried in the sacred books of the Parsees and in the cuneiform characters. Subsequent to the destruction of the Persian empire by Alexander the Great, the documents of the religion of Ormuzd, founded by Zoroaster, were neglected under the reign of the foreign princes. The new Persian dynasty of the Sassanides

(226–651) reestablished the ancient religion in its former dignity, and the extant fragments of the holy books were carefully gathered. The conquest by the Arabs dethroned the native religion again, and almost wiped it out of existence. A few succeeded in retaining the ancient worship in Persia, as in Yezd and Ker-man, and others introduced it into India. The remains of the holy books extant at the time of the Arab conquest are still preserved, partly in the original language, but mostly in an ancient translation. The oldest Iranic form of speech known to us was probably an eastern language, and Spiegel has given it the name of Old Bactrian. Others designate it as Zend, which was originally intended to be applied to the translation, but was subsequently used by mistake for the language of the text. The language of the translation is Huzvaresh, which is the literary form of the Pehlevi. Anquetil-Duperron published in 1771 a French translation of the text under the title *Zend-Avesta*. (See ZEND-AVESTA.) The hints which he gave of the language were sufficient to prove its Sanskrit character, and Sir William Jones was the first to identify it as such (1789); but a whole generation passed before any real progress in the recovery of the language was noticeable. When the labors of Bopp and Schlegel had given a solid foundation to Sanskrit philology, the Iranian languages soon gained a similar basis through the labors of Olshausen, Burnouf, Hermann Brockhaus, Spiegel, Westergaard, Haug, Justi, Lagarde, and Lassen. The first attempt at a grammar of the Old Bactrian or Zend language was made by Haug in his "Essays on the Sacred Language, Writing, and Religion of the Parsees" (Bombay, 1862). In 1867 appeared Spiegel's *Grammatik der Alt-baktrischen Sprache*, containing also an appendix on the dialect of the Gathas. Justi published in 1864 a *Handbuch der Zendsprache*, in which he furnished a lexicon of Old Bactrian, to which Paul de Lagarde has made valuable additions in his *Beiträge zur baktrischen Lexikographie* (1868). (See ZEND LANGUAGE.) For the old Persian language of the time of the Achæmenides, as found on the monuments of Cyrus, Darius, and Xerxes, see CUNEIFORM INSCRIPTIONS. Benfey, Mordtmann, and others are of opinion that the second column of the trilingual cuneiform inscriptions contains the language of the ancient Medes.—The language called Pehlevi, Pahlavi, or Huzvaresh, is Iranic, but it is not positively known where and when it was spoken. Spiegel assigns it to the western portion of the empire of the Sassanides, and considers its Semitic elements of Nabathæan origin. It was probably used as a literary language from about the 3d century to the downfall of the Sassanian empire, and continued in use for religious documents. It is known through the translation of the *Avesta*, and through a few other religious works, as the *Bundehesh*, and through inscriptions, coins, and gems. It is not always the same, but dif-

fers in these various remains principally in a smaller or larger infusion of Semitic elements. Müller, Haug, Windischmann, Dorn, Mordtmann, Olshausen, De Sacy, and Levy are probably the most eminent scholars of Pehlevi. The language called Parsee or Pazend resembles Pehlevi in grammar, but its vocabulary has few words of Semitic origin, and is purely Iranic. It was probably in use at the same time as the Pehlevi, the literary language of the Sassanian empire, and finally became its successor. It maintained itself as such until the development of the modern Persian. When used in explanation of ancient religious texts, the Parsee language is styled Pazend. Spiegel published in 1851 a grammar of this language.—The modern Persian is purely Iranic in its older documents, but since the adoption of Islam the vocabulary has been full of Arabic words, though the grammar has remained essentially Iranic. (See PERSIA, LANGUAGE AND LITERATURE OF.) East of the territory of modern Persian are the Iranic dialects of the Afghans and Belooches, and west those of the Ossetes, Kurds, and Armenians, noticed in the articles relating to them.—See F. Spiegel, *Erânische Alterthums-kunde* (2 vols., Leipzig, 1871-'3).

IREDELL, a W. county of North Carolina, partly bounded W. by Catawba river, and drained by branches of the Yadkin; area, 695 sq. m.; pop. in 1870, 16,931, of whom 4,643 were colored. It has an uneven surface and a good soil. The Western railroad passes through it. The chief productions in 1870 were 67,687 bushels of wheat, 315,972 of Indian corn, 108,657 of oats, 67,071 lbs. of tobacco, 13,233 of wool, 86,058 of butter, 40,273 of honey, and 408 bales of cotton. There were 1,920 horses, 980 mules and asses, 2,738 milch cows, 4,608 other cattle, 9,723 sheep, 15,731 swine, and 1 cotton factory. Capital, Statesville.

IREDELL. **I. James**, an American jurist, of Irish ancestry, born in Lewes, England, Oct. 5, 1751, died in Edenton, N. C., Oct. 20, 1799. He emigrated to America at the age of 18, and was made comptroller of the customs at Port Roanoke, now Edenton, N. C., retaining the office for several years. He was admitted to the bar in 1770, was deputy attorney general in 1774, judge of the supreme court of the state in 1777, and attorney general in 1779-'82. In 1787 he began the collection published as "Iredell's Revision of the Statutes of North Carolina" (1791). In 1790 he was appointed a justice of the United States supreme court. His judicial opinion in the case of *Chisholm v. Georgia* contains the germs of all the later doctrines of state rights. The "Life and Correspondence" of Judge Iredell has been published by Griffith J. McRee (2 vols. 8vo, New York, 1857). **II. James**, son of the preceding, born in Edenton, Nov. 2, 1788, died in Raleigh, April 13, 1853. He graduated at Princeton in 1806, studied law, and served for ten years in the North Carolina house of commons, being twice speaker. In the war of 1812 he commanded a company of

volunteers. In 1819 he occupied during one circuit a seat on the bench of the superior court, declining a further appointment. In 1827 he was governor of the state, and from 1828 to 1831 a member of the United States senate. He afterward resumed the practice of his profession at Raleigh, and for many years was the reporter of the state supreme court. He published 13 volumes of law and 8 of equity reports. In 1833 he was appointed one of three commissioners to collect and revise all the statutes in force in North Carolina; the result was the work known as the "Revised Statutes." He afterward published a "Treatise on the Law of Executors and Administrators."

IRELAND, a European island, forming part of the United Kingdom of Great Britain and Ireland, situated between lat. 51° 26' and 55° 21' N., and lon. 5° 20' and 10° 26' W. It is bounded N., W., and S. by the Atlantic ocean, and E. by St. George's channel, the Irish sea, and the Northern channel, which separate it from England and Scotland. In shape it is a rhomboid, the greater diagonal of which is 300 m. and the smaller 210 across; greatest meridional length 230 m., greatest and smallest breadth 180 and 110 m.; area, 32,531 sq. m. It is divided into four provinces, Leinster, Munster, Ulster, and Connaught, and 32 counties, which, with their population and chief towns, are as follows:

PROVINCES AND COUNTIES.	POPULATION.		Chief towns.
	1861.	1871.	
LEINSTER.			
Carlow.....	57,187	51,472	Carlow.
Dublin.....	410,252	405,625	Dublin.
Kildare.....	90,946	84,198	Naas.
Kilkenny.....	124,515	109,802	Kilkenny.
King's.....	90,043	75,751	Tullamore.
Longford.....	71,694	64,408	Longford.
Louth.....	90,773	84,198	Drogheda.
Meath.....	110,873	94,480	Navan.
Queen's.....	90,650	77,071	Maryborough.
Westmeath.....	90,879	75,416	Mullingar.
Wexford.....	143,954	132,506	Wexford.
Wicklow.....	56,479	75,509	Wicklow.
MUNSTER.			
Clare.....	166,805	147,994	Ennis.
Cork.....	544,818	516,046	Cork.
Kerry.....	201,800	196,014	Tralee.
Limerick.....	217,277	191,818	Limerick.
Tipperary.....	249,106	216,210	Tipperary.
Waterford.....	184,252	122,825	Waterford.
ULSTER.			
Antrim.....	378,588	419,782	Belfast.
Armagh.....	190,086	179,221	Armagh.
Cavan.....	153,906	140,555	Cavan.
Donegal.....	287,395	277,775	Donegal.
Down.....	299,302	217,992	Downpatrick.
Fermanagh.....	105,768	92,688	Enniskillen.
Londonderry.....	184,209	173,932	Londonderry.
Monaghan.....	126,482	112,785	Monaghan.
Tyrone.....	238,500	215,668	Dungannon.
CONNAUGHT.			
Galway.....	271,478	243,257	Galway.
Leitrim.....	104,744	95,324	Carrick-on-Shannon.
Mayo.....	254,796	245,855	Castlebar.
Roscommon.....	157,272	141,246	Roscommon.
Sligo.....	124,845	113,311	Sligo.
Total.....	5,798,624	5,402,759	

In 1821, when the first complete census was taken, the population amounted to 6,801,827; in 1831, to 7,767,401; in 1841, to 8,199,853; in 1851, to 6,514,473. The great decrease from 1841 to 1851, amounting to about 1,600,000, was due to the intervening famine and the increasing emigration. The number of inhabited houses was 995,156 in 1861, 960,352 in 1871.—The coast line is about 750 m. long. From Malin head in the extreme north to Cape Clear in the south, it is comparatively but little broken, and is low and flat, except in the northeast, where the shore is rugged and precipitous; and navigation in the east is much obstructed by sunken rocks, bars, and sand banks. Between the two points named the chief openings in the coast are the loughs of Foyle, Belfast, Strangford, and Carlingford; the bays of Dundrum, Dundalk, and Drogheda; that of Dublin with the artificial harbor of Kingstown, those of Wexford, Waterford, Dungarvan, and Youghal; the magnificent harbor of Cork, including Queenstown; and Kinsale, Courtmacsherry, Clonakilty, Rosscarbery, Baltimore, and Skibbereen harbors. On the southwest, west, and north the coast presents the aspect of the southern and western coasts of Norway, being broken into narrow strips and ragged fragments by firths and arms of the sea. These form numerous bays and harbors, among which are: on the southwest and west, the bays of Dunmanus, Bantry, Kenmare, and Ballinskelligs, Valentia harbor, the bays of Dingle and Tralee, the estuary of the Shannon, navigable for large vessels to Limerick, Liscanor and Galway bays and the Killarries, Clew bay with the harbors of Westport and Newport, Blacksod bay, and Broad Haven; further north, Killala, Sligo, and Donegal bays, with Sheep Haven and Lough Swilly. The shores on this side of the island are composed of lofty cliffs; on the coast of Donegal they form in some places a perpendicular wall of 760 ft. On the northern coast are the celebrated colonnades of the Giant's Causeway, near Coleraine, and of the promontories of Bengore and Fairhead, where the basalt rests on chalk-white limestone, beneath which appear the greensands of the lias. Scattered along the coast are 196 islands, the principal of which are: on the E. coast, Lambay; on the S. E., the Saltees and Tuscar rock; on the S., Clear island; on the W., the Skelligs, Valentia, the Blaskets, the South Arran isles, Inishbofin, Inishturk, Clare in Clew bay, the Achill islands, and the Inishkea islets; and on the N., the North Arran isles, the Tory isles, and Rathlin. The total number of harbors is 90, of which 14 receive ships of any draught, 17 admit frigates, upward of 30 are deep enough for coasting vessels, and 25 for good summer roadsteads. There are also numerous inlets which afford a shelter to the largest fishing craft. There are 62 lighthouses, of which 26 are first-class lights.—The surface is divided into a central basin and mountain masses fringing the coast, with two great open-

ings on the east and west. Between these openings the central plain extends from Dublin to Galway and Clew bay, reaching northward as far as Lough Neagh and southward to the borders of Waterford and Cork. It is diversified by rich and rolling uplands rising to 200 and 320 ft. above the sea, and by flat tracts of sterile bog lying like huge black patches amid the universal green. The high hills and mountains are covered to their summits with heather. As compared with England, the country has but few trees and patches of forest, although in former times it bore the name of Island of Woods. Strictly speaking, there are no mountain ranges, if we except the Slieve Bloom and Devil's Bit mountains, which stretch in an irregular curve of about 30 m. through N. E. Munster and W. Leinster. Elsewhere the mountains form isolated masses near the coast, subsiding rapidly as they recede from it. The principal groups are: in the northwest, the Donegal mounts, highest point Errigal, about 2,500 ft.; in the northeast, those of Down, highest point Slieve Donard, 2,800 ft.; in the west, Truskmore in Sligo (2,100 ft.), Nephin and Mulrea in Mayo (about 2,700 ft.), and Twelve Pins in Galway (2,400 ft.). Kerry boasts the loftiest peaks in Ireland: Brandon, 3,120 ft., and Carn Tual, 3,414 ft. Of the Waterford mountains, Mona Vullagh is 2,600 ft.; of the Wicklow, Lugnaquilla is 3,000 ft.; of the Dublin, Kippure is 2,470 ft. In Antrim the hills form an elevated plateau intervening between Lough Neagh and the North channel; Mt. Divis near Belfast is 1,560 ft., and Trostan further north 1,800 ft.—The great interior basin is chiefly covered with mountain limestone, through which protrude the Slieve Bloom and Slieve Baughta mountains, both consisting of clay slates between red and yellow sandstone. This clay-slate formation is the second in extension. It flanks the limestone plain to the east, abutting on the Wicklow granite mountains, extending thence westward into Kildare and eastward through Wicklow and Wexford to the sea, and from the western side of the Wicklow mountains reaching in a series of elevations southward and westward through Kilkenny and Tipperary to Limerick, Cork, and Kerry. They compose the mountain masses of Slievenamon, Knockmeledown, and Galtee, together with those which cover Kerry, terminating at Brandon head. Clay slates appear on the S. W. border of the Antrim trap bed, covering Down, Armagh, Monaghan, and Louth, with parts of Cavan, Meath, Longford, and Roscommon. Through this clay-slate tract in the north protrude the granite ridges of Mourne and Slieve Gullion. The granitic rocks form the Wicklow and Mt. Leinster groups, and appear to the north of Galway bay mixed with greenstone and quartz, Mulrea being the culminating point. From Mulrea northward to Killala lie a series of primitive rocks, principally mica slate and protruded quartz, forming the barrier between the ocean and the great central plain. This

barrier is broken only by the limestone plain of Mayo, extending to the shore of Clew bay. Mica slate and granitic ridges extend northward and eastward through Sligo to Donegal, forming almost the entire surface of the latter county and a great portion of Londonderry and Tyrone. In the N. W. part of this district the granite and quartz are intermixed with veins of primitive limestone, which also mingles with the mica slate constituting the remainder. East of this granite and mica slate district lies the great trap field of Antrim, the erupted rock over an extent of 800 sq. m. capping a stratum of indurated chalk, which rests on lias. Patches of the same metamorphic rocks also appear on the coast of Kerry, and on that of Antrim, where they terminate in Fair head. The ancient Irish annals contain many accounts of land eruptions proceeding from volcanic action; and in more modern times two are noticeable: one in 1490 at the Ox mountains, Sligo, by which 100 persons and numbers of cattle were destroyed; and a volcanic eruption in May, 1788, on the hill of Knocklade, Antrim, which poured a stream of lava 60 yards wide for 39 hours, and destroyed the village of Ballyowen and all the inhabitants save a man, his wife, and two children. The immense extent of bog is a great obstacle to a perfect knowledge of Irish geology. The coal fields, with the exception of a small field of bituminous coal in the west and a few patches in the north, are south of the centre of the island. The quality of the coal is inferior. The most valuable bed is in Kilkenny, and is made up of seven workable seams of anthracite, the coal containing from 94 to 96 per cent. of pure carbon. The largest field covers a considerable tract in the southwest; but the coal is not well adapted for domestic use, and is chiefly employed in malting and lime burning. In Tyrone, the district of Coal Island produces coal of good quality used in the neighborhood; the beds seldom exceed a few inches in thickness. In 1772, at Ballycastle, Antrim, a colliery was discovered, with gallery and branches, which, from the stalactite pillars and the sparry incrustations on the sides and supports, is believed to have been worked before the Norman invasion. Lignite, the only tertiary deposit, is found on the S. shore of Lough Neagh. The clay-slate formation contains copper ore, the chief mineral wealth of Ireland, the principal mines of which are in the counties of Wicklow, Waterford, Cork, and Tipperary. Lead is more abundant than copper; but in Ireland the mountain limestone is much less liberally supplied with it than in England. The coal measures are rich in iron; and silver is found in connection with lead ore in proportions varying from 7 to 120 oz. per ton. Native gold associated with magnetic ironstone was found toward the end of the last century in Wicklow, but all the efforts of the government to discover an available vein proved fruitless. Tinstone also exists in the same locality, but no working deposits have been discovered. Recent explorers have found

in the new red sandstone beds of salt promising an inexhaustible supply. The other minerals known to exist are antimony, zinc, nickel, iron pyrites, alum, clays of various kinds, gypsum, ochre, building stone, marble, and paving and roofing slates. Mineral springs occur at Mallow, where the water is 20° warmer than the atmosphere, and at Castle Connell, near Limerick, where the waters are chalybeate; and sulphur springs at Swanlinbar in Cavan, and at Lucan near Dublin.—Of the two kinds of bogs, the red or fibrous consists chiefly of bog moss (*sphagnum palustre*); it is reddish brown, approaching to olive when dry. Its surface is generally covered with heath. The black bog varies from dark brown to perfect black; in the latter case it becomes very hard and close-grained, and breaks into angular fragments. The deepest layers are still denser and darker, and very compact, resembling pitch or coal, and emitting when lighted an offensive odor. The average depth of these bogs is 25 ft.; in some places they attain a depth of 40 ft. They are always above the sea level, their greatest height being 488 ft. and lowest 25 ft. The peat is found to rest on a blue clay, and ultimately on gravel. The area of bog available for peat fuel is about 2,830,000 acres. This physical disposition accounts for the hydrographic features of Ireland. From any part of the country navigable water can be reached within a distance of 50 m. Few countries are so well supplied with rivers and lakes. The principal river is the Shannon, the largest in the United Kingdom, which has its source in the county Cavan at the foot of Mt. Cuilcagh, and in a course of 250 m. forms Loughs Allen, Ree, and Derg. The other principal streams are the Blackwater, which has its estuary near Youghal; the Suir, the Nore, and the Barrow, which have their estuary near the city of Waterford; the Slaney, emptying into St. George's channel at Wexford; the Boyne, flowing N. E. from the elevated plain of Linstear into the Irish sea at Drogheda; the Bann, rising in the Mourne mountains, and flowing northward through Lough Neagh till it empties into the Atlantic at Coleraine; the Foyle, emptying into the lough of that name, and formed by the union of four streams from the interior of Ulster; the Erne, falling into Donegal bay; and the Liffey, flowing into Dublin bay. The principal of the numerous lakes are Lough Neagh in Ulster, the largest lake in the United Kingdom, covering 98,255 acres, and exceeded in extent on the continent of Europe by only a few lakes outside of Russia and Sweden; Lough Erne in Fermanagh, consisting of two lakes 5 m. apart, connected by the fine river of that name; Lough Corrib and Lough Mask in the west of Connaught, separated by an isthmus 3 m. broad; Lake Conn in the north of the same province; and the lakes of Killarney in Kerry, renowned for their beauty.—Giraldus Cambrensis praises the mild and equable climate of Ireland. At Dublin the mean annual temperature is a little

lower than 50° F.; the mean winter temperature is 40°, spring and autumn 50°, and summer 60°. There is a difference of 3° between the average temperatures of the extreme north and south. The average temperature of any month in each season varies but slightly from the above figures. There is perpetual moisture, which fosters vegetation and maintains unfailing pasturage; this is due to the prevalence of westerly winds which bring with them the tepid vapor-laden atmosphere of the Gulf stream. Hence the climate of the W. coast of Ireland is milder than that of the W. coast of England in the same latitude. The average spring temperature of Queenstown is 50°, the highest in the British isles. The average annual rainfall is estimated at 36 in., but in some elevated regions, as in Kerry, it is much higher. In the west the rainfall is much greater in winter than in the other seasons. Prolonged frosts and snows are rare, and thunder storms are neither frequent nor violent. The prevalent winds are from the west and south, the S. E. wind predominating in the early part of the year. Easterly winds are dry and keen and much dreaded by invalids. The climate on the whole is very salubrious. The frequency among the poorer classes of fevers and dysentery is attributed less to the humidity of the atmosphere and the exhalations from marsh and bog, than to unwholesome and insufficient diet, imperfect clothing, damp and close dwellings, and want of cleanliness.—One fourth of the entire surface is covered with sterile rock, water, marsh, and bog; arable soil of a mediocre quality composes another fourth; and the remainder is a deep rich loam generally covering a calcareous subsoil. This rich loam, with a subsoil of inferior depth, and producing a luxuriant herbage, is found throughout Roscommon, in some parts of Galway, in Clare, and in other districts. Both the loam and the subsoil attain their greatest depth in Meath, Longford, Tipperary, and Limerick; the Golden Vale district, belonging to the last two counties, is celebrated for its fertility. On the banks of the Fergus and Shannon the soil is different, though equally productive, and very marshy in appearance. These districts are called "caucasses;" the substratum is a blue silt deposited by the sea and partaking of the quality of the upper stratum, thus allowing the whole to be advantageously ploughed to any depth. In Limerick and Tipperary is another kind of rich soil, consisting of a dark, friable, sandy loam, which if kept clean will yield grain for several generations; it is equally well adapted for tillage and pasture, and seldom suffers either from extreme drought or excessive rain. The subsoil, being calcareous, needs no manuring. In the north the quantity of rich soil is not very considerable; but valleys of uncommon fertility are found in every county, even amid the bleak mountains of Donegal. In some parts, as in Galway, the rock protrudes above the surface in wave-like projections, and the interstices are filled with a

mould producing a thick sward very grateful to sheep. The only large tract exclusively devoted to sheep grazing is the Curragh of Kildare. The mountains are capable of cultivation to a considerable height, and their summits with few exceptions are fit for pasturage in summer. Indeed, both from soil and climate, Ireland is naturally a pastoral country; nor was it till 1727 that any systematic effort was made at large culture, when Primate Boulter, as one of the lords justices, urged on the English government the necessity of enforcing a tillage system. In the northern counties the farms are generally small, cultivated with the spade, and yield potatoes, oats, and flax. In the northern part of Fermanagh the farms are larger, the tillage better, and wheat is largely grown, oats however being the chief crop. In the five counties forming the northwest of Ireland, oats is the principal crop, and barley is raised near the sea; and since the famine of 1846 much of the land formerly under tillage has been converted into pasturage. In the southwestern counties grazing is more resorted to, tillage backward, and the farms small. In Tipperary and King's and Queen's counties the best farming is to be seen, wheat forming the staple crop. In Meath, Westmeath, Louth, and Kildare the tillage is inferior, the farms larger and treated after the English manner, and the chief crop is wheat. As the mean summer heat is 56°, the finer sorts of grain ripen in the island; while the open winters, by lengthening the period of grazing, favor the rearing of cattle. The country is very deficient in wood, although it is said to have been formerly covered with forests. The timber found in the bogs is oak, fir, yew, holly, and birch. The progress of agricultural improvement, and the timber act, which secures to the tenant at the expiration of his lease a pecuniary interest in the trees he has planted, promise a large supply of wood in future. Ireland is rich in cattle, horses, especially hunters, and sheep (with less wool than the English). There are many rabbits, but little game excepting deer. Fish abound, especially the salmon, pike, eel, and trout. The sunfish frequents the W. coast, which is occasionally visited also by whales. Seals are met with about the exposed headlands. There are frogs, but no toads or serpents. Bones of the elk or moose deer have been found in several places. Wolves were once numerous, and the Irish wolf dog was kept for hunting them. Of poultry the product is extensive. The flora of Ireland includes the *arbutus unedo* along the lakes of Killarney; new species of saxifrage and ferns have been discovered on the Kerry mountains; rare alpine plants are met with in Connemara (Galway), Benbulbin mountain (Sligo), and in the county Antrim, and peculiar kinds of algæ on various parts of the coast.—The majority of Irishmen resemble in temperament the southern rather than the northern races of Europe. This is most apparent in those parts of Ireland where English and Scotch

settlers do not preponderate. They are more impulsive and warm-hearted than the people of England and Scotland. As settlers in other parts of the world, especially in the United States, the Irish have proved very useful and industrious in various kinds of manual occupation, but at home they are principally tillers of the soil. A marked improvement in the condition of the country has taken place within the last 30 years. The work of bringing waste lands into cultivation reduced the uncultivated land from 6,295,735 acres in 1841 to 5,023,984 in 1851, and to 4,357,338 in 1871. Emigration, which had been powerfully stimulated by the potato disease of 1846-'7, showed a steady decrease for several years after 1852. In that year it was 190,322; 1853, 173,148; 1854, 140,555; 1855, 91,914; 1856, 71,724; 1858, 64,337; 1865, 101,497; 1866, 99,467; 1867, 80,624; 1868, 61,028; 1872, 72,763; whole number from 1851 to 1872, 2,157,257. The total number of paupers relieved was, in 1848, 2,043,505; 1850, 1,174,267; 1851, 755,347; 1852, 519,775; 1853, 409,668; 1854, 319,616; 1857, 190,851; 1861, 217,430; 1863, 317,624; 1866, 270,173; 1868, 339,728; 1871, 282,492. The following statement shows the progress of the agricultural wealth of the country: land under cultivation in 1854, 5,570,610 acres; 1858, 5,882,052; 1868, 5,498,278; 1872, 5,486,522. Of the last number, 2,090,673 were under cereal crops, 991,802 under potatoes, 346,464 under turnips, 135,650 under other green crops, 122,003 under flax, and 1,799,930 were meadow and clover. The produce in 1871 was as follows: wheat, 705,939 quarters; oats, 7,410,814; barley, bere, and rye, 965,709; beans and peas, 49,690; potatoes, 2,793,641 tons; turnips, 4,246,332; mangel and cabbage, 761,863; flax, 12,929. The live stock in 1872 consisted of 560,500 horses and mules, 180,036 asses, 4,057,153 cattle, 4,262,117 sheep, 242,310 goats, 1,385,386 pigs, and 11,612,207 poultry. The aggregate value of the live stock was estimated in 1841 at £21,105,808; in 1851, £27,737,395; 1861, £33,434,385; 1871, £37,515,111.—The linen manufacture is the most important branch of Irish industry. The spinning wheel of the Ulster cottier gave place to the spindle in the early part of this century, when the first flax-spinning machinery was erected. The number of flax factories has increased from about 70 in 1849 to 154 in 1870, with 916,660 spindles and 14,834 power looms, employing 55,039 persons. One of the chief seats of this manufacture is Belfast. Of cotton factories there were 14 in 1870, woollen factories 61, and worsted factories 3. The silk manufacture, which was introduced into Dublin by French emigrants at the end of the 17th century, proved unprofitable; almost the only branch now flourishing is a fabric of mixed worsted and silk, known as Irish poplin or tabinet. Lace is manufactured to some extent in Limerick. Great progress has been made within the last few years in the manufacture of embroidered muslin. The chief
